The reversible reaction of deoxyribonucleic acid (DNA) and Hg^{II} has been known for some nine years[1] during which it has been studied by a wide variety of techniques[1-4]. All the studies concur in demonstrating that the binding is quite strong but can nevertheless be completely reversed by a variety of common chemical reagents which complex Hg^{II}. After reversal the DNA is both structurally and functionally intact despite the large changes in physical properties which accompany and characterize the reaction. Initially thought to be a reaction which occurred primarily with phosphoryl groups[1] it was later convincingly suggested by Thomas[2] that the reaction occurred primarily at the bases. A few years later this observation was confirmed and extended to a greater variety of polydeoxyribonucleotides[3,5] and most recently to the polyribonucleotide of tobacco mosaic virus[6].

The mechanism of the reaction has remained a puzzle, however, in spite of many suggestions. The purpose of this communication, therefore, is to outline briefly a step-function mechanism which can incorporate the known facts and is capable of predicting many as yet unknown experimentally.

In their recent work Yamane and Davidson[5] showed that H$^+$ is released when Hg^{II} reacts with DNA. They examined the hydrogen ion release as a function of added increments of Hg^{II} and were able to obtain plots of $\Delta H^+/\Delta Hg^{++}$ as a function of r for several kinds of DNA as well as *A–T* polymer, a synthetic polydeoxyribonucleotide. The quantity ΔH^+ is the average release of hydrogen ion when a small quantity ΔHg^{++} is added to a solution of a polynucleotide^{II}. The quantity r is the number of moles of Hg^{II} added per mole of nucleotide.

The mechanism assumes that all or nearly all the Hg^{II} added up to $r = 0{\cdot}5$ reacts to form 2 : 1 base—Hg^{II} complexes; that the complexes bridge the double strands of the DNA helix; that Hg^{II}—(thymidine)$_2$ complexes are much more readily formed than any of the other possible 2 : 1 compounds; that a chain shift induced by Hg^{II} occurs such that complementary bases opposite each other in the original unperturbed structure are displaced by an Hg^{II} bridge to the nearest (opposite) neighbour and that as a first approximation the bases in the natural DNA's are distributed as random along the chain. Knowing the formulæ of all the 1 : 1 nucleoside—Hg^{II} complexes[6] it is not hard to make reasonable formulæ for all the 2 : 1 nucleoside complexes (the 2 : 1 adenosine—Hg^{II} complex has been reported[6]) and with these and the assumptions given above to construct step functions to fit the curves of Yamane and Davidson. Fig. 1 shows an example of the fit of such a function to the data for *E. coli* DNA. The curves for calf-thymus and *M. lysodeikticus* DNA's and *A–T* polymer can be similarly constructed. The positions and extents of the plateaux and abrupt drops which are obvious in the curves of Yamane and Davidson find a natural and general explanation in the mechanism. In addition, the mechanism lends itself readily to the more elaborate treatments of 'binding' available[7]. It is already sufficiently successful quantitatively to permit the prediction that the Hg^{II} reaction of polynucleotides can be used in fundamental studies of nucleotide sequence and in determination of the base composition of polynucleotides. These and other ramifications will be discussed at length elsewhere.

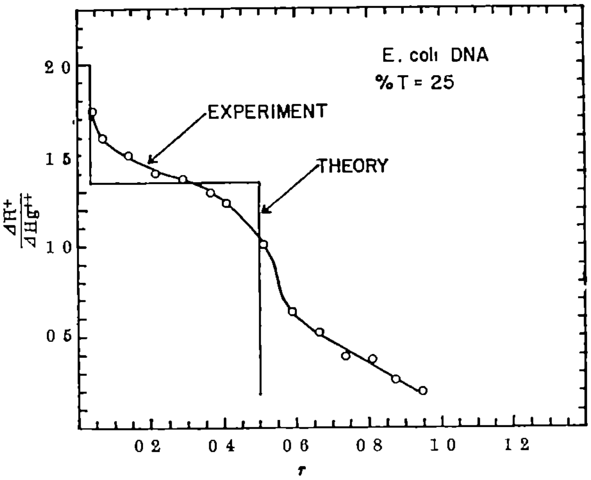

Fig. 1. The fit of a step-function theory to the data of Yamane and Davidson

CHEMISTRY

A Transparent Semiconducting Indicator Electrode

During the course of an investigation of the photosensitivity of silver halide precipitates, the need for a transparent, conducting electrode sensitive to halogens became evident. A new practical solution to the problem has been found by the use of thin

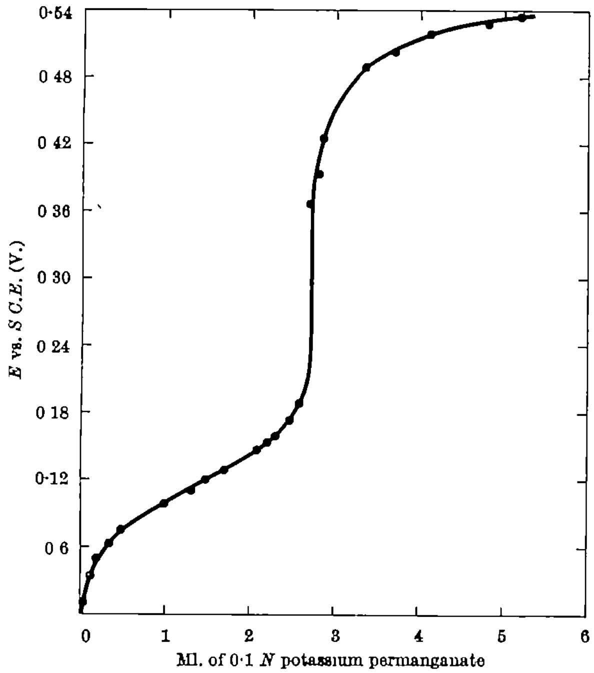

Fig. 1. Titration of 10 ml. of 0 0269 *N* ferrous sulphate with 0 1 *N* potassium permanganate

layers of stannic oxide coated on glass (*NESA* *) as an indicator electrode.

The electrode is prepared from a piece of *NESA* glass 4 cm. × 2·5 cm. in area and 3 mm. thick; the semiconducting layer on one surface is 0·05–0·5μ thick and has a specific resistivity of about $2{\cdot}5 \times 10^{-4}$ ohm-cm. Since stoichiometric tin oxide ordinarily has a far higher specific resistivity, the layer probably contains added impurities; for example, layers of stannic oxide containing antimony oxide, deposited on glass, are known to exhibit low specific resistivity[1]. Silver paste is applied over the semiconductor layer at the upper end to facilitate good electrical contact, by means of an 'alligator' clip, with the external circuit. The lower half of the electrode is partially immersed in the solution to be titrated; the reference electrode is either platinum sheet connected to the titration solution by a salt bridge or a fibre-tipped saturated-calomel electrode. Changes in potential are measured by a Keithley 200*B* vacuum-tube voltmeter.

The electrode is highly sensitive to halogen solutions added to 0·001 *M* potassium halides, acquiring a positive potential with respect to the reference electrode. At bromine concentrations from $2{\cdot}5 \times 10^{-6}$ to 8×10^{-5} *M*, the potential at the stannic oxide electrode was found to vary linearly with the square root of the bromine concentration. Small, but distinct, break points in plots over a larger concentration-range suggest the formation of charged polynuclear halide species, or of hydrolysis products which contribute to the potential. The latter is a distinct possibility since hypobromite ion was found to yield a potential at the electrode. At a given concentration of halogen, the potential decreased in the order: $Cl_2 > Br_2 > I_2$. The order is similar to that for the oxidation potentials of halogens referred to the normal hydrogen electrode.

The electrode was highly sensitive to the following ions: MnO_4^-, Ce^{++++}, $Cr_2O_7^{=}$, $S_2O_3^{=}$, Ti^{+++}, Tl^+ and NO_2^- ions. These observations suggested the feasibility of the stannic oxide as an indicator electrode for potentiometric investigation of oxidation-reduction reactions.

Fig. 1 shows a titration of ferrous ion with standard permanganate ion in 1 *N* sulphuric acid solution. On addition of the titrant, electrode equilibrium was rapidly established. It can be seen that the rate of change of potential at the equivalence point is large, enabling a ready determination of the end-point. To illustrate further the utility of stannic oxide as an indicator electrode, iodine was titrated by standard thiosulphate ion. Rapid changes of potential also occurred at or near the equivalence point for the titration. However, on the addition of excess thiosulphate ion, the electrode responded sluggishly and came slowly to equilibrium.

The results seem to show that stannic oxide can be utilized as an indicator electrode and that the properties of transparency in the visible region, reproducibility and durability suggest a variety of uses. For example, in certain circumstances, such as oxidation-reduction in concentrated chloride solutions, stannic oxide might be superior to platinum as the indicator electrode, for the formation of $PtCl_4^{=}$ tends to make the latter inaccurate[2].

Hydrogen–Deuterium Exchange on Iso-structural Sesquioxides of the First Long Period

Investigations of the relationship between the electronic structure and the catalytic activity of transition metal oxides have tended to centre around either the electron (or positive hole) concentration[1] or the population of atomic *d* orbitals[2]; but there have been no attempts so far to follow up in this field the newer studies on electrical and magnetic properties which reflect the extent of *d* orbital overlap in the oxides of the first long period[3,4]. Moreover, although it is now widely recognized that the energy-levels of transition metal ions in solids are strongly influenced by the symmetry of the crystal field, there are no correlative studies of catalytic activity in which this important parameter has been standardized. It is for these reasons that we have undertaken a short study of the H_2–D_2 exchange on sintered specimens of titanium, vanadium and chromium sesquioxides. The ions Ti^{3+}, V^{3+} and Cr^{3+} follow in the sequence d^1, d^2 and d^3, and in the almost cubic field of the corundum lattice (which is common to all three oxides) one would expect the progressive filling of the degenerate $d\varepsilon$ set to ensure a gradual decrease in the amount of orbital overlap along this sequence.

Ti_2O_3, V_2O_3 and Cr_2O_3 are immune to bulk reduction by hydrogen, so the H_2–D_2 exchange can be examined at quite high temperatures and the use of well-crystallized specimens becomes practicable. Ti_2O_3 was prepared by reduction of TiO_2 in a $TiCl_4/H_2$ stream at 750° C.; V_2O_3 was prepared by reduction of V_2O_5 in hydrogen at 800° C.; Cr_2O_3 was obtained by ignition of $(NH_4)_2Cr_2O_7$ at 800° C. A circulating

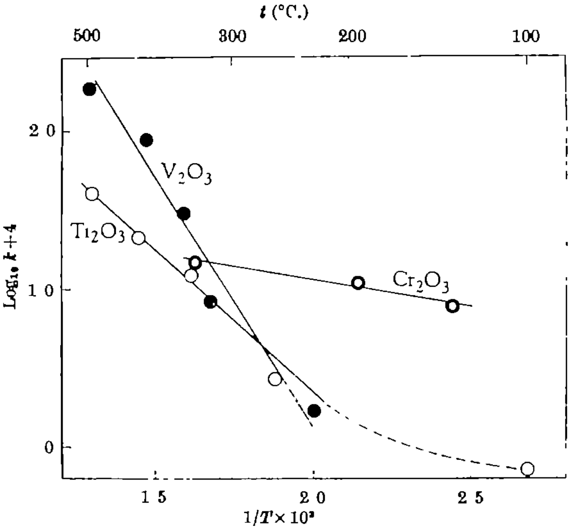

Fig. 1. The activity of Ti_2O_3, V_2O_3 and Cr_2O_3 in H_2–D_2 exchange

system[1] was used for the exchange experiments. The course of the reaction was followed by withdrawing samples from time to time and analysing them in a mass spectrometer. The kinetics can be expressed in terms of a first-order rate constant k, referred to unit surface area. Thus:

$$k = \frac{1}{At}\ln\{[HD]_\infty/([HD]_\infty - [HD]_t)\}$$

where A is the area of catalyst used. Arrhenius plots showing the values of k(m.$^{-2}$min.$^{-1}$) at various temperatures between 100° and 500° C. are given in Fig. 1.

It is immediately apparent that the simple correlation of an activity increase in the sequence d^1, d^2, d^3 claimed for this reaction by Dowden, Mackenzie and Trapnell[2] is not borne out by the results presented here. $V_2O_3(d^2)$ is the most active oxide at high temperatures and the least active at low temperatures. Below 300°, however, the well-known activity of chromia for this reaction is clearly demonstrated. H_2–D_2 exchange has normally been studied on 'unglowed' chromia gel, which is active even at −196°; but the crystalline oxide evidently retains the characteristic property which determines catalytic activity at low temperatures. It suggests that Cr^{3+} stabilized in the octahedral holes of the oxide lattice is genuinely responsible. The greatest interest is attached to the high activity of Ti_2O_3 and V_2O_3 at high temperatures, as reflected by their much larger activation energies. Now the corundum structure is basically a hexagonal close-packed lattice of oxide ions with the cations regularly occupying two-thirds of the octahedral holes. There is, however, some distortion. The result is that each cation has one near neighbour and three other cation neighbours somewhat farther away. A pair-wise interaction due to the overlap of the occupied d orbitals of the near neighbours is then possible in these transition metal sesquioxides[5], and, other things being equal, this overlap will be greatest for Ti^{3+} with its smaller nuclear charge. The resultant coupling of the spins leads to an unusual antiferro magnetism in Ti_2O_3 and V_2O_3, but Cr_2O_3 has much more conventional magnetic behaviour, suggesting that this pairing is either absent or very weak. It would appear that the onset of catalytic activity in Ti_2O_3 and V_2O_3 does not occur until these spins are uncoupled. This begins to occur with V_2O_3 at about −100°, but is not complete until 300° (ref. 6). With Ti_2O_3 the unpairing begins at about 100°, but is much less susceptible to a rise in temperature[7]. The catalytic activity is seen to follow this general pattern, suggesting that the critical step is indeed the formation of a covalent d bond between the metal and adsorbed hydrogen, as Dowden, Mackenzie and Trapnell have surmized[2]. The relationship with conductivity is also interesting. Once the temperature is high enough for the magnetic exchange interaction to be removed, the semiconductivity of Ti_2O_3 and V_2O_3 disappears and the band structure approximates to that of a metal[3,4]. The d-metals are generally good catalysts for hydrogen chemisorption and for the H_2–D_2 reaction, and the relatively high activity of Ti_2O_3 and V_2O_3 which we find above 300° now extends the analogy.

Reduction of Osmic Acid by Ultrasonic Waves

It is assumed that water decomposes under the influence of the ultrasonic waves into free radicals according to the equation:

$$H_2O = H + OH$$

The radicals are responsible for some secondary reactions which depend on the medium treated.

In aqueous solutions some substances react with hydrogen atoms, others with OH radicals. On the other hand, in an ultrasonic field reduction or oxidation occurs according to the properties and structure of the reacting ions and particles.

Beuthe[1] has observed that a dilute solution of potassium permanganate becomes decolorized when, under ultrasonic treatment, and mercuric chloride, to which ammonium oxalate has been added, is reduced to mercurous chloride. Moreover, it has been shown that some other substances, inorganic and organic, are reduced in an ultrasonic field[2–6].

In our experiments an ultrasonic generator (quartz) of 500-kHz. frequency and 5-W./cm.^{2} power, and a cylindrical glass vessel with a very thin bottom the diameter of which (3·5 cm.) was equal to the diameter of the vibrating quartz plate, were used.

The quartz plate and the reaction vessel were cooled down by flowing oil through. Solutions of osmic acid, in concentrations of 1–2 per cent, were at first saturated with hydrogen and in the course of the ultrasonic treatment about 50 hydrogen bubbles per min. were passed through them. After subjection to ultrasonic treatment the solution was poured into a long test-tube. In every case 20 ml. of osmic acid solution were treated with the ultrasonic waves.

Effect of Osmium Tetroxide on the Efficiency of the Reaction. Osmium tetroxide solutions (0·1–1·9 per cent) were treated with ultrasonic waves for 3 min. The interdependence of the concentration and the

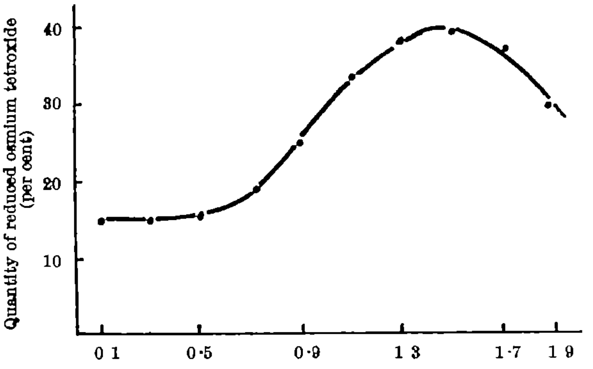

Fig. 1

amount of reduced osmium tetroxide is shown in Fig. 1. A decrease in the efficiency of the osmium tetroxide reduction reaction in solutions of concentration higher than 1·5 per cent is explained by the fact that a certain maximum concentration of colloidal osmium tetroxide particles disperses a part of ultrasonic energy.

After treatment, the solutions of low concentration (0·1–0·5 per cent) were of an ashen colour with a bluish shade while the solutions of higher concentration (above 0·5 per cent) were dark blue.

Osmic acid in the ultrasonic field is reduced under the influence of hydrogen to colloidal OsO_2 according to the equations:

$$H_2 = H + H$$

$$OsO_4 + 4H = OsO_2 + 2H_2O$$

The degree of the colloidal division of OsO_2 is so great that only after a few days do OsO_2 particles show a tendency to settle in the solutions of the highest concentration. But when 0·5–1 ml. of the saturated solution of ammonium sulphate is added, then a sudden coagulation of OsO_2 particles takes place. A visual observation of the velocity of the sedimentation of OsO_2 particles leads to the conclusion that most of them belong to a monodispersal system, as the absolute number of OsO_2 particles settles down with the same velocity. The solutions of colloidal OsO_2 obtained are able to decompose hydrogen peroxide.

The solutions of osmic acid acidified with 2 *N* hydrochloric acid give less colloidal OsO_2. Under these conditions H radicals at *p*H less than 3 change into H_2^+ ions according to the equation:

$$H + H^+ = H_2^+$$

with strongly oxidizing properties.

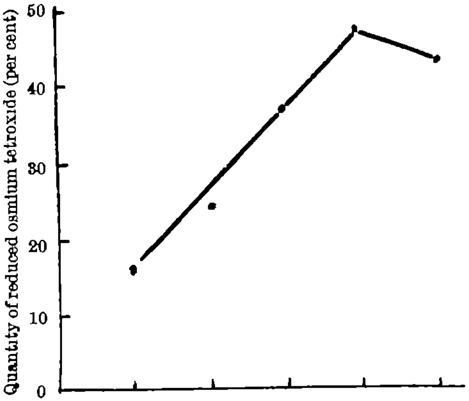

Fig. 2

Effects of Duration of Ultrasonic Treatment on the Quantity of Reduced Osmium Tetroxide. 20 ml. of 0·7 per cent osmium tetroxide solution were treated for 2, 4, 6, 8 and 10 min. The interdependence of the quantity of reduced tetroxide and duration of the treatment are shown in Fig. 2.

After the treatment for 1 min. no change occurred. Probably after that duration of treatment the concentration of H radicals is too low to start the reduction of osmium tetroxide. During the course of further treatment the solutions turned blue because colloidal OsO_2 was formed, the particles of which showed no tendency to sediment even after some days. Colloidal OsO_2 precipitated by ammonium sulphate and then air-dried turned black. Precipitated OsO_2 can decompose hydrogen peroxide.

Centrifugal Fractionation of Wool Wax

It has recently been reported[1,2] that complete or almost complete fractionation of wool wax into oxidized and unoxidized fractions occurs during centrifugal recovery from the scouring liquor. We have already[3] found evidence of a rapid fall in the high peroxide value of the wax emulsified in the hot scouring liquor, a slow fall continuing even in the cold, and unless centrifugal separation takes place during or immediately after scouring, all the wax in the liquor is almost peroxide-free and centrifuging does not give fractions of very different peroxide value. The peroxides presumably break down to the usual ultimate oxidation products such as ketones and fatty acids, and these fatty acids tend to remain in the alkaline liquor as soap, thus contributing to the fractionation of oxidized products during centrifuging. This is supported by the much higher acid value which Anderson and Wood[1] found in their 'unrecovered' compared with their 'recovered' wax.

That fractionation occurs, involving not only fatty acids, has long been accepted in the British lanolin industry. Thus, pharmaceutical-quality wool fat (anhydrous lanolin) refined from centrifuged wool grease, compared with wool fat refined to a similar acidity and general standard from the 'unrecovered' grease (which, in Britain, is often recovered by 'acid-cracking'), differs in odour, colour, melting-point, free cholesterol content, etc., and individual users of pharmaceutical wool fat often show a preference for one particular type, not necessarily that of centrifugal origin.

It seems unlikely that centrifugal fractionation of oxidized substances is as complete as has been claimed. Anderson and Wood[1] found centrifuged wool grease to have approximately four times the acid value and hydroxyl value of new wax solvent-extracted from the base of the fleece, and their ultra-violet absorption spectra of the two waxes showed considerable differences. Also new wax has been reported[4-6] as substantially colourless, neutral, and of saponification value as low as 73, whereas most centrifuged wool grease is very different in all these respects (for example, the saponification value is usually > 90).

It appears probable that more than direct oxidation is responsible for the darkening in colour and other changes which are undergone by wool wax on the fleece and which are involved in the centrifugal fractionation. In contrast to the lightening in colour which occurs during oxidative bleaching or surface autoxidation of most types of wool wax, we have found that when peroxides in wool fat are rapidly broken down by heating or treatment with sulphur dioxide, potassium iodide, etc., the colour darkens and the acid value rises, the breakdown being accelerated by presence of metals (iron, copper, etc.) or by an acid pH such as prevails in oxidized wool fat[7]. The causes of the change may possibly be summarized as: autoxidation, catalysed by metallic impurities present[5,6], the resultant peroxides undergoing natural or accelerated decay under the influence of chemical or biological reduction (possibly catalase-like[8]) and/or metallic catalysts, with simultaneous formation of dark-coloured metallo-organic compounds and absorption of substances (including nitrogen, phosphorus and perhaps sulphur[4,10]) from the suint, excreta and, possibly, degraded wool.

BIOCHEMISTRY

Incorporation of Carbon-14 from Labelled Sodium Bicarbonate into the Retina of the Rat

Since respiration and glucose metabolism in retina are more rapid if bicarbonate is added to the incubation medium[1,2], it was of interest to investigate the metabolic pathways by which carbon dioxide can be assimilated during such incubation. In the experiments reported here the bicarbonate was labelled with carbon-14 and the radioactive products formed during incubation were separated and located by chromatography followed by autoradiography.

One or two rat retinæ were placed in 200 μl. phosphate Ringer solution containing 1 μmole glucose and 1 μmole sodium bicarbonate; the solution was gassed with oxygen and incubated for 10 min. at 37°. 50 μl. aqueous carbon-14 labelled sodium bicarbonate (containing 0·4 μmole/10 μc.) was then added and incubation was continued for 5–30 min. and stopped by addition of 1 ml. absolute ethanol. The metabolites soluble in aqueous ethanol were separated and located by chromatography and autoradiography by a method similar to that described by Moses[3].

Ten active compounds were detected by this treatment, but in most of them radioactivity was very slight. The more active compounds were identified by co-chromatography of the extract with suitable markers. The identification of fumaric, malic, aspartic and glutamic acids and of glutamine was confirmed by elution of these compounds on to fresh chromatograms, which were run with authentic markers, in two different solvent systems. The remaining compounds had low activity and were not identified; one may have been lactic acid. An attempt was made to isolate keto acids from an *m*-phosphoric acid extract of the incubation mixture as the 2 : 4-dinitrophenylhydrazones[4]. The hydrazone fraction showed an activity of 100 counts/min./retina compared with 2,000 counts/min./retina for the whole extract, but it was not possible to identify individual keto acids. The activity both of the whole extract and of the hydrazone fraction was similar for extracts incubated for 5 or for 30 min. The count for the whole extract corresponded to the incorporation of approximately 0·1 per cent of the added bicarbonate. This is lower than that recorded by Katz and Chaikoff[5] for rat liver and the pattern of incorporation is also different from that reported for other mammalian tissues[5,6]. A higher rate of incorporation might have been expected from Crane and Ball's[7] results, but these workers added pyruvate as well as glucose to the incubation medium. In our experiments carbon-14 was distributed among a number of intermediary metabolites; much shorter incubation periods would have been required to prevent further reaction of the first products of fixation, but the small amount of carbon-14 assimilated would probably have precluded their identification, and experiments of this kind are unlikely to throw light on the effect of bicarbonate in glucose metabolism in retina.

Micro-fractionation on Paper of Acidic Polysaccharides and Related Substances

In 1955, Scott[1,2] described a method for the preparative separation of polysaccharides containing different amounts or types of anionic residues, based on the formation of insoluble complexes with cetyl pyridinium chloride (CPC) or similar long-chain cations. The resulting complexes can be selectively dissociated by varying concentrations of electrolytes (sodium sulphate, sodium chloride, magnesium chloride)[3,4].

We have now extended this principle for the separation of polyuronides, sulphated polysaccharides and related substances, on paper strips in the quantitative range 5–70 μgm., using upward elution from the corresponding CPC complexes in a magnesium chloride gradient (0–3·5 *M*).

The elution apparatus consists of a glass cylinder (7·5 × 42 cm.) fitted for magnetic stirring and containing 10 ml. of water. Into this, a saturated solution (20° C.) of magnesium chloride is introduced by an electrically driven syringe at a rate of 1·8 ml./hr. The polysaccharide mixtures are prepared for separation in the following way. The end (4–5 cm.) of a strip (5 × 46 cm.) of Whatman No. 4 paper (with a line ('origin') drawn 3 cm. from its lower edge) is dipped in 10 per cent (w/v) solution of CPC in 95 per cent ethanol for 10 min. The paper is dried and a solution (in 50 μl.) of polysaccharides (5–70 μgm. of each constituent) is applied as a spot on the 'origin'. Up to three samples can be examined simultaneously, arranged as in conventional chromatography. The paper is dried gently, and excess CPC is then removed by washing in 95 per cent ethanol or other suitable solvent. The paper is again dried, and it is then equilibrated with water vapour by being suspended in a moist chamber for 12 hr.

The resulting paper is rapidly transferred to the elution apparatus, where it is suspended with the lower edge just immersed in the eluting medium, which is gently stirred magnetically. The apparatus is closed and the introduction of magnesium chloride is commenced at once. In the course of 5 hr., the solvent rises to a height of about 30 cm. The electrolyte gradient is approximately linear up the paper.

The eluted paper is washed (5 min.) in 95 per cent ethanol and the separated components may be detected by a variety of methods, for example, Alcian Blue[5], a general reagent for mucoproteins, hyaluronic acid, etc., mucicarmine[6], for mucopolysaccharides, etc., Azur *A*[7] for metachromatic substances such as chondroitin sulphate and for some sialic acid-containing substances, and periodic acid–Schiff reagent[8] for components containing oxidizable carbohydrates. The method has also been used successfully with mucopolysaccharides labelled with carbon-14 or sulphur-35 and for their dinitrophenyl derivatives.

The procedure gives clear and reproducible separations of substances such as: heparin, chondroitin sulphates, colonic mucoproteins, dextran sulphate, hyaluronic acid.

In a typical separation, lasting 4 hr. 40 min., in which the solvent front was at 32·0 cm. (measured from the origin), heparin migrated 4·2 cm., chondroitin sulphate 8·4 cm., hyaluronic acid 12·9 cm. The procedure appears to offer considerable promise for the separation and comparison of these types of mucosubstances.

Effect of Adenine Nucleotides on Phagocytizing Guinea Pig Leucocytes

PHAGOCYTOSIS has been used predominantly as an indicator for estimating the effect of chemical agents on the reticuloendothelial system[1]. As an outcome of investigations on the mechanism of action of biologically interesting compounds on phagocytosis, it has now been found that adenosine triphosphate (ATP) is a powerful inhibitor of this phenomenon without affecting respiration, glucose utilization and lactic acid production of the leucocytes. Similar effect was observed, though less pronounced, with adenosine diphosphate (ADP), adenosine monophosphate (AMP) and diphosphopyridine nucleotide (DPN).

The effect of ATP at various concentrations on phagocytosis by guinea pig exudate mononuclear cells of the heat-treated *Mycobacteria X* was investigated (Fig. 1). Leucocytes were collected by saline washing the peritoneal cavity of bled animals 5 days after intraperitoneal injection of 10 ml. 12 per cent sterile solution of sodium caseinate. The centrifuged (10 min. at 220*g*) leucocytes were resuspended for the phagocytosis experiments in *p*H 7·4 bicarbonate buffered Krebs-Ringer solution containing 5 per cent heat-inactivated rabbit serum and 0·15 per cent glucose. The total yield was 50–150 × 10^6 leucocytes (80–85 per cent monocytes) per animal. Three times saline-washed and heat-treated (1 hr. at 60° C. in saline) *Mycobacteria X* (ref. 2) from 3–4-week-old cultures on Dubos-'Tween'-albumin medium were used as a 0·100 optical density (625 mμ) saline stock suspension. Phagocytosis was measured by a modification of the method described by Suter[3] using 0·2 ml. of the *Mycobacterium X* stock suspension per 0·8 × 10^6 leucocyte. After incubation for 1 hr., in presence or absence of the compound to be tested, the coverslips were washed in saline twice to eliminate the extraneous bacteria, fixed in methanol, dried, stained with cold carbolfuchsin[4] for 8 min., washed with water, decolorized, counterstained for 1 min. with 0·3 per cent aqueous methylene blue, dried and mounted. Counting was effected until a total of approximately 100 bacteria-containing leucocytes were enumerated. The phagocytic index (*P.I.*) was calculated by using the formula:

$$P.I. = \frac{\text{no. of leucocytes containing bacteria}}{\text{total No. of leucocytes counted}} \times 100$$

Each point on the graph represents the mean values of five experiments. Statistical analysis, by calculating the probabilities on the basis of the null hypothesis for true difference between the control and test values,

a, Resting cells. *b*, phagocytizing cells.

* Uptake of oxygen was examined in a Warburg respirometer. The main compartment contained $35–40 \times 10^6$ cells in a total volume of 2 5 ml. phosphate buffered Krebs-Ringer solution, containing 5 per cent heat-inactivated rabbit serum and 100 mgm per cent glucose. The side arm contained either (*a*) 0 5 ml. of Krebs-Ringer solution, or (*b*) the compound in the medium alone, or (*c*) *Mycobacterium X* (same count as for phagocytosis experiments) in the medium alone, or (*d*) *Mycobacterium X* and the compound tested together in 0 5 ml. of the medium. The centre well contained 0 2 ml. of 10 per cent potassium hydroxide. After equilibration for 20 min., the side-arm was tipped 30 min. after the start of the readings. Measurements of uptake of oxygen were continued for a total period of 210 min. The reaction was stopped by the addition of $10^{-4} M$ sodium azide and the contents of the flasks were centrifuged. The supernatant fluid was used for the glucose (ref. 14) and lactic acid (ref. 15) determinations

gave $P < 0{\cdot}001$ for all concentrations above $1 \times 10^{-6} M$, $0{\cdot}05 < P < 0{\cdot}1$ for $1 \times 10^{-6} M$ and $0{\cdot}1 < P < 0{\cdot}2$ for $1 \times 10^{-7} M$.

Fig. 1 shows that, depending on the concentration, ATP slightly enhances or considerably inhibits phagocytosis by guinea pig leucocytes. In contrast to this effect on phagocytosis, ATP does not affect noticeably the respiration, glucose utilization and lactic acid production of resting and phagocytizing mononuclear cells (Table 1). At $1 \times 10^{-2} M$ AMP inhibited phagocytosis, but had no effect at lower concentrations. With ADP the cells came off the coverslips at concentrations of $1 \times 10^{-3} M$, $5 \times 10^{-3} M$ and $1 \times 10^{-2} M$. The drastic effect of ATP on phagocytosis, which involves cytoplasmic deformation, is not unexpected since cytoplasmic streaming, which is the basis of cell motility, has been considered to be akin to muscle contraction and relaxation processes[5–7]. That AMP also has some inhibitory action at the concentration of $1 \times 10^{-2} M$, where ATP exerts considerable inhibition, suggests, however, that the effect of ATP may not be solely related to its utilization as source of energy. This is also consistent with the absence of action of ATP on the glycolysis of leucocytes. Thus, simpler mechanisms, such as multipoint attachment to functional groups of the cellular surface structure (that is, cross-linking by secondary valence forces (cf. ref. 8)), should be considered for the observed inhibition of phagocytosis.

Also DPN has a marked inhibitory effect on phagocytosis at both $5 \times 10^{-4} M$ and $5 \times 10^{-3} M$ (22 and 45 per cent decrease of the phagocytic index relative to the control), while DPNH is an inhibitor only at $5 \times 10^{-3} M$ (38 per cent decrease). On the respiration and on the glycolysis of mononuclear cells, however, addition of DPN appeared to have some stimulatory effect. Only small difference was found in the uptake of oxygen by resting and phagocytizing leucocytes. There was no difference in glucose utilization and no change in lactic acid production[9].

In contrast to the findings of Sbarra and Karnovsky[10], and Cohn and Morse[11] on the effect of metabolic inhibitors on polymorphonuclear cells, iodoacetate, fluoroacetate and sodium fluoride at $1 \times 10^{-4} M$, and sodium azide and *p*-chloromercuribenzoate at $5 \times 10^{-5} M$ were either without effect on phagocytosis in our assay system, or produced slight stimulation. However, 2,4-dinitrophenol was markedly inhibitory at $5 \times 10^{-4} M$. Cysteine, glutathione and *p*-mercaptobenzoate at $5 \times 10^{-3} M$ were without effect, which is in general agreement with the observations of Lisowski[12] with various sulphydryl compounds. The sulphydryl inhibitor dicarbonyl compounds, diacetyl, acetylacetone and acetonylacetone (all at $5 \times 10^{-3} M$), were inhibitory to phagocytosis to various degrees. However, acetone and also ethanol had a considerable stimulatory effect both on the percentage of active leucocytes and on the number of particles taken up by the phagocytes.

The observations[13] that bacterial lipopolysaccharides stimulate the phagocytic activity of guinea pig polymorphonuclear cells could not be observed in our system. There was no effect with concentrations of 0·1–50 μgm./ml. Pre-incubation of the cells with this material had some inhibitory effect on phagocytosis.

Because it is conceivable that components of the serum may interact with some of the compounds tested, the use of media containing no serum was attempted. Considerable drop in the phagocytic index was observed when the experiment was carried out in bicarbonate buffered Krebs-Ringer solution in the absence of serum. Rabbit leucocytes were found to be much more sensitive (*P.I.* = 2·5) to the absence of serum than were guinea pig leucocytes (*P.I.* = 23·0), while control experiments conducted in presence of sera of various species and at various levels gave *P.I.* values between 55·0 and 69·0 for the leucocytes of both species.

This investigation was supported by the U.S. Public Health Service research grant *E*–1302 *C*2 to Dr. Emmanuel Suter, whom we thank.

Determination of Volatile Anæsthetics in Rhesus Monkey Tissue

METHODS for the facile quantitation by infra-red spectrophotometry of such anæsthetics as diethyl ether or chloroform and its congeners in animal tissues have been developed within our organization[1–3]. Extensive results which we obtained from anæsthetized dogs are being reported[3]. The results of experiments on higher primates are somewhat different and some of their peculiarities are of more general interest.

The healthy, large animals used were secured in a supine position and anæsthetized without premedi-

cation by inhalation of diethyl ether, chloroform, methoxyflurane ($CH_3OCF_2CCl_2H$) and halothane ($CF_3CBrClH$) vapours, administered by conventional clinical equipment for 2·5 hr. The ordinary details are described elsewhere[3] and followed modern human clinical practice on the whole[4].

Expired air samples were collected within 5 min. at 2 and 2·5 hr. of anæsthesia through a one-way valve leading into 2-litre gas-tight saran bags. The concentration of anæsthetic in the bag was determined directly in a 10-cm. gas cell in a Perkin-Elmer 221 infra-red spectrometer. Blood samples were taken from the femoral artery while the air samples were being collected. After 2·5 hr. of anæsthesia, the animals were killed abruptly by means of a large intravenous dose of sodium pentobarbitone. The tissues were immediately dissected out and prepared for analysis. Blood and tissue samples of diethyl ether, chloroform and methoxy flurane were extracted by carbon disulphide and the content of anæsthetic in the extract quantitated by infra-red spectrometry[1]. In the case of halothane, tissue samples were analysed by extracting into *n*-hexane with quantitation of the bromine contained in halothane by means of X-ray fluorescence spectrometry as explained elsewhere[2]. The overall analytic error is about ± 10 per cent with either method of analysis and all sources of error would lead toward lower than actual values.

The data obtained are presented in Table 1. The arterial blood-levels of all the drugs are several-fold lower than required in the dog for a comparable anæsthesia. Such data as exist for man[4,5] are most comparable with the monkey. Brain-levels, generally, of ether, chloroform and methoxyflurane were found to be higher than arterial blood-levels, while those of halothane are distinctly lower. This difference was not seen in the dog. No obvious differences in anæsthetic concentration among different brain areas were detected, although there is a trend toward higher concentrations in the cerebellum and medulla.

The very high concentration of all these anæsthetics found in the whole adrenal and in the thymus defies immediate explanation. It cannot be a simple solution, for in the cases of the fluorinated anæsthetics it exceeds the level found in omental fat. The low level of halothane in the ovary of the one female examined must be accepted with reservation, although we have no reason to doubt its correctness. The relative ease with which determinations of many anæsthetics can now be made, despite the complex apparatus required for quantitation, intimates that this, and many other questions, will soon be answered.

Anaerobic Formation of *n*-Hept-1-ene from *n*-Heptane by Resting Cells of *Pseudomonas aeruginosa*

Two of us (E. A. and J. C. S.) have previously shown[1,2] that *Pseudomonas aeruginosa* metabolizes anaerobically *n*-heptane through an adaptative dehydrogenase coupled with pyocyanin and/or diphosphopyridine nucleotide (DPN). The formation of the corresponding 1-olefine as the product of the reaction was suggested on the basis of certain indirect evidence, but still had to be analytically demonstrated. The

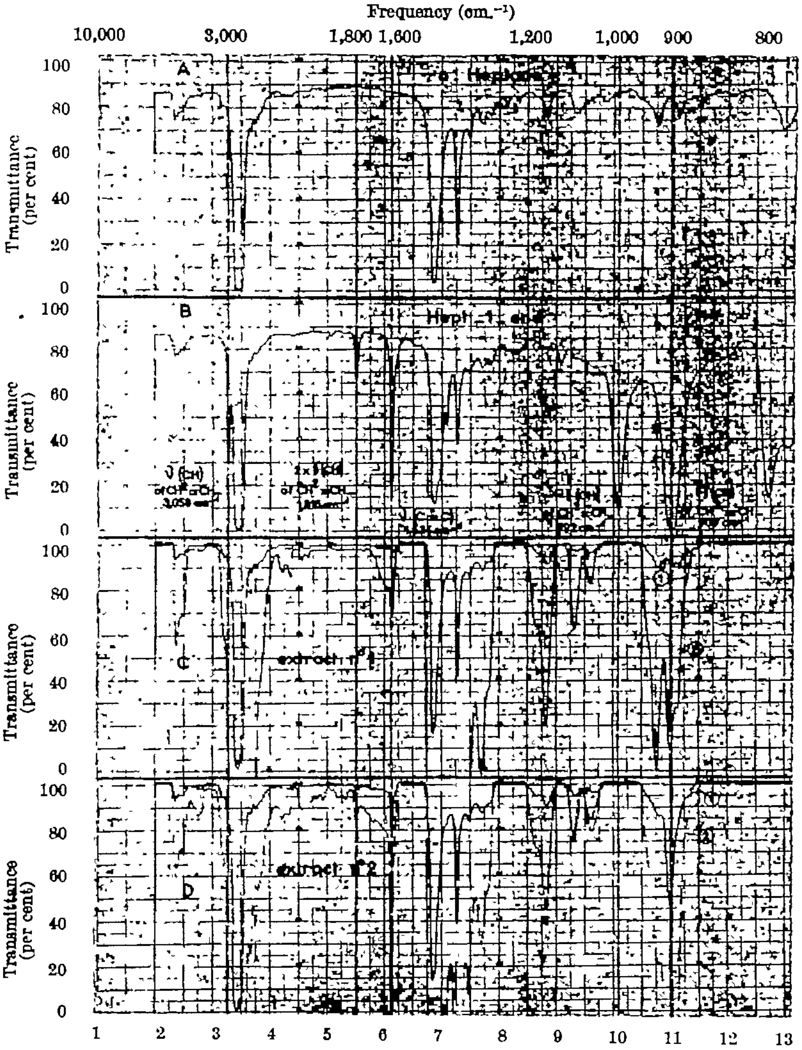

Fig. 1. *A* and *B*, Infra-red spectra of pure *n*-heptane and *n*-hept-1-ene in a 0·025-mm. cell; *C* (extract No. 1), carbon tetrachloride extract of an experimental system initially containing 70 mgm. *n*-heptane; 1·0 mm. cell; curve 1, without scale expansion, curve 2, with 10-times scale expansion; *D* (extract No. 2), spectra of a carbon tetrachloride batch utilized for successive extraction of nine experimental systems, each containing initially about 40 mgm. *n*-heptane; 1·0 mm. cell, curve 1, without scale expansion; curve 2, five-times scale expansion

results reported here provide an infra-red spectrophotometric confirmation of this pathway.

In order to minimize the possible interference of intra-cellular material with the spectrophotometric characterization of the olefine, the experiments were carried out with intact cells of *P. aeruginosa* (strain *S* 20) cultivated on *n*-heptane as already described[2]. The reactions were performed in Thunberg's tubes, under the following conditions: bacterial cells; 10–20 mgm. dry-weight; purified pyocyanin[4], 5 μmoles; *n*-heptane, 40–70 mgm.; total volume completed to 25 ml. with 0·05 *M* phosphate buffer (*p*H 7·0). Prior to the introduction of the substrate, the systems containing all the other constituents were frozen at − 15° C., this precaution excluding any possibility of an aerobic oxidation of the alkane by the bacteria during the interval of time between the preparation of the systems and the evacuation of the tubes.

In these experimental systems, the substrate (*n*-heptane) is in considerable excess, and complete reduction of the external electron acceptor (pyocyanin) theoretically corresponds to the formation of 490 μgm. (5 μmoles) of heptene.

After the evacuation of air, the systems were allowed to equilibrate at + 23° C. and the reaction pursued for about 30 min., until complete discoloration of pyocyanin. The tubes were then cooled again to 0° C., opened, and the systems were extracted with 4 ml. of cold carbon tetrachloride. The solvent was thoroughly mixed, separated by centrifugation at 0° C. and its spectrum recorded with a Perkin–Elmer model 21 infra-red spectrophotometer in a 1 mm. cell. The absorption of the solvent (carbon tetrachloride) was compensated for by using a variable thickness cell and adjusting for the absorption band of carbon tetrachloride at 9·4μ (1,064 cm.⁻¹).

The following products have been utilized for the dehydrogenation assays and the recording of reference spectra: (1) *n*-heptane A.P.I. grade, 99·8 per cent pure (commercial product from Phillips Co.); (2) *n*-hept-1-ene (purity 99·80 ± 0·10 per cent), *trans*-*n*-hept-2-ene (purity 99·85 ± 0·05 per cent), and *trans*-*n*-hept-3-ene (purity 99·80 ± 0·15 per cent), kindly provided by the British Petroleum Research Laboratories (Sunbury-on-Thames); (3) pure 1-*n*-heptanol, heptanal, heptanoic acid and methylheptanoate kindly provided by Organico Research Laboratories (Marseilles).

Preliminary assays have shown that the initial quantity of *n*-heptane introduced in the bacterial systems must not exceed 70 mgm., in order to avoid the masking of the olefine spectrum by the excess alkane. The minimum concentration of *n*-hept-1-ene detectable in carbon tetrachloride with a 20-times ordinates scale expansion is of about 70 μgm./ml. Under these conditions, only the characteristic bands of absorption described by Sheppard and Simpson[5] at 909 cm.⁻¹ [γ(CH)] and 1,634 cm.⁻¹ [ν(C = C)] are faintly visible. With the same scale expansion, the peak at 3,058 cm.⁻¹ [ν(CH)] becomes apparent for a concentration of 700 μgm./ml. With a concentration ten times higher, the two last peaks at 1,815 cm.⁻¹ [2 × γ(CH)] and 992 cm.⁻¹ [γ(CH)] become faintly visible without scale expansion and are quite marked with a 5-times scale expansion.

It has been verified that repeated extraction of control systems containing the bacteria, pyocyanin and buffer in the absence of *n*-heptane does not introduce into the carbon tetrachloride any contaminating material which could interfere with the spectrophotometric detection of the olefine.

The original spectra reproduced in Fig. 1*C* (extract No. 1) correspond to a single carbon tetrachloride extraction of an experimental system initially containing 70 mgm. of *n*-heptane. The characteristic bands of hept-1-ene at 909 cm.$^{-1}$ and 1,634 cm.$^{-1}$ are clearly visible without scale expansion (curve 1) and much more marked with a 10-times scale expansion (curve 2). On curve 2, the absorption band at 3,058 cm.$^{-1}$ forms a distinct shoulder on the adjacent band of *n*-heptane. The spectra in Fig. 1*D* have been recorded on a sample of carbon tetrachloride which had been used for the successive extraction of 9 experimental systems, each containing initially about 40 mgm. *n*-heptane. On these spectra, the three aforementioned bands are clearly visible and also the band at 1,815 cm.$^{-1}$. The absence of the fifth characteristic band (992 cm.$^{-1}$) is due to the fact that the very strong absorption of carbon tetrachloride in this range cannot be exactly compensated for and was actually overcompensated.

The chemical structure of the olefine formed in the reaction is demonstrated by the absence of the single characteristic absorption band[3] of *trans*-hept-2-ene and *trans*-hept-3-ene. The absorption bands of the corresponding *cis*-heptenes[3] are not interfering with the bands of the other *n*-heptenes and are too weak to be apparent in the carbon tetrachloride mixtures. The complete absence of the characteristic bands of 1-*n*-heptanol, *n*-heptanal, heptanoic acid and methylheptanoate should be also noted.

Increased Sensitivity of Ethylenediamine Analysis for Norepinephrine

ATTEMPTS have been made to increase the sensitivity of analysis for catecholamines using the ethylenediamine condensation method described by Weil-Malherbe and Bone[1]. The objective was to be able to determine catecholamine-levels of 0·05 μgm. and below. Examination of the intensity of fluorescence of norepinephrine after various periods of heating demonstrated, in agreement with others[2,3], that 1–2 hr. heating at 50° C. was optimum. It was also possible to obtain the same intensity of fluorescence by permitting the reaction to proceed at room temperature for about 7 hr. or at 5° C. overnight. At 50° C. the intensity of fluorescence was found to be maximum in 20 min. for epinephrine and in 40–50 min. for dopamine. When using the Klett fluorimeter, the fluorescence for epinephrine was stable while that for norepinephrine and dopamine was not.

As reported previously[2], intense ultra-violet light caused a rapid decrease in intensity of fluorescence. In the Klett fluorimeter, the intensity of the ultraviolet light was great enough to cause a significant drop in fluorescence during the time it took to null the meter. Exposure to the incident beam for more than 5 sec. could be avoided by measuring the deflexion of the galvanometer beam rather than using the galvanometer as a null point meter. During this time the decrease in fluorescence was minimal. With the Aminco-Bowman spectrophotofluorometer, the fluorescence from norepinephrine and dopamine decreased more slowly, and, for practical purposes, could be considered stable. When the proper activation and fluorescent wave-lengths were used, the intensity of the fluorescence from norepinephrine was somewhat greater than from epinephrine. This improved sensitivity of the method still would not permit the analysis of 0·05 μgm. or less of norepinephrine. Examination of the extractability of the fluorescent product of norepinephrine with various volumes of isobutanol yielded the results given in Table 1. It was observed that a 12-fold concentration of the fluorescent product is possible by decreasing the volume of isobutanol from 3·0 to 0·25 ml. By using micro-cuvettes and the following slit arrangement: (1/16, 1/32, 1/8, none, none, none and 1/16 in. openings for slits No. 1, 2, 3, 4, 5, 6 and 7 respectively), one is able to detect as little as 0·0075 μgm. of norepinephrine.

Table 1. FLUORESCENCE OBTAINED WITH 0 2 μGM. OF NOREPINEPHRINE FOLLOWING EXTRACTIONS OF 5 ML. OF 0·2 *N* ACETIC ACID WITH VARIOUS VOLUMES OF ISOBUTANOL

Sample No.	Isobutanol Vol. (ml.)	Fluorescent units
1	3 00	0 012
2	1 50	0 024
3	0·75	0 045
4	0 50	0 075
5	0 25	0 162

This simple modification of the procedure has been used successfully for the determination of catecholamine-levels in isolated rabbit arterial strips.

Phytic Acid as a Phosphorus Reservoir in the Developing Potato Tuber

PHYTIC acid is present in the mature potato tuber, as a mixture of dicalcium monomagnesium salts of inositol hexa- and penta-phosphoric acids[1,2]. The present communication provides information on the effect of maturity and post-harvest storage temperature on the phytic acid content of the potato tuber. Table 1 shows that the phytic acid phosphorus content of freshly harvested tubers increases with increasing maturity, but does not change greatly on subsequent storage at either 25° or 0°. Table 1 also shows that the percentage of total phosphorus present as phytic acid increases with increasing maturity, especially during later stages of development. Thus two-thirds of the increase in phosphorus content per 100 gm. of tuber observed between 80 and 102 days after planting appears as phytic acid phosphorus, whereas at earlier stages of development the incoming phosphorus is preferentially incorporated into starch[3]. Between two-thirds and four-fifths of the total organically bound acid-soluble phosphorus is present in the tuber as phytic acid phosphorus[2]. Although the phytic acid contributes a substantial portion of the total phosphorus of the tuber, its concentration in tubers amounts to less than 0·1 per cent of the fresh weight of the tuber.

Table 1. PHYTIC ACID CONTENT OF POTATO TUBERS

Post-harvest conditions	Days after planting 60	80	102	60	80	102

* Phytic acid phosphorus was estimated as the sum of the phosphorus content of (*a*) the acid insoluble precipitate from treatment of a trichloroacetic acid extract of potatoes and (*b*) that fraction of acid soluble phosphorus that is retained on a 'Dowex-1-chloride' column after chromatography with eluting agents of Khym and Cohn (ref. 5). The phytic acid fraction can be quantitatively removed from the column by elution with 1 *M* hydrochloric acid. Proof of the identity of at least 99 per cent of the phosphorus of fractions (*a*) and (*b*) with phytic acid phosphorus has been published elsewhere (ref. 6).

These results suggest that phytic acid, together with starch, may function as a reservoir for accumulating phosphorus in the maturing potato tuber. By preventing the accumulation of relatively high concentrations of inorganic phosphate and thereby limiting the metabolic activity of the tuber[4], phytic acid might serve to prepare the tuber for post-harvest dormancy. In this sense phytic acid phosphorus, in contrast with starch phosphorus, can be considered as ballast material rather than as a ready source of phosphorus.

2-Hydroxyphenylacetic Acid, a New Constituent of Higher Plants

IN connexion with our work on the biogenesis of plant stilbenes the formation of hydrangeic acid in *Hydrangea macrophylla* was studied[1]. To evaluate possible intermediates we attempted to identify all phenolic and acidic constituents of the species *Hydrangea macrophylla* by a new technique which uses fractional sublimation in a horizontal tube prior to paper chromatography. This makes possible the clear identification of those constituents which are present in very small amounts.

This work was extended to 19 species of 9 genera of the family of Saxifragaceae[2]. Most of the compounds found are well known as plant constituents, for example, caffeic, *p*-coumaric, *p*-hydroxybenzoic, vanillic, gentisic and ferulic acids. The only compound found which has so far not been detected in higher plants was 2-hydroxyphenylacetic acid. The only natural occurrence of this C_6–C_2 compound so far reported seems to be in the mother liquor of *Penicillium* cultures[3]. This compound could be isolated from various species of the genus *Astilbe*. In *Astilbe chinensis* it is the major acid constituent and amounts up to 0·05 per cent dry weight of the leaves whereas in roots only 0·005 per cent was found.

After extraction by ethanol and evaporation of the ethanol the free acids were obtained by treatment of the residue with ether. The glucosides remained in the aqueous phase and their aglucones were extracted after acid cleavage. Sublimation of the crude acids (140°, 0·01 torr) yielded a mixture consisting mainly of 2-hydroxyphenylacetic, vanillic and 4-hydroxybenzoic acid. These compounds were separated by thin-layer chromatography ('Kieselgel *G*,' Merck, diethylether: di-*n*-butylether, 100 : 1). 2-Hydroxyphenylacetic acid was eluted from the gel. After a second sublimation white crystals of m.p. 148° were obtained. Identity with an authentic sample of this compound was proved by mixed melting point, infra-red and ultra-violet spectra (absorption maxima 275 mμ ($\varepsilon = 2{,}090$) and 227 mμ ($\varepsilon = 2{,}250$), minimum at 243 mμ).

Since 2-hydroxyphenylacetic acid seems to be present only in the genus *Astilbe* and could not be found in any other genus of the family of Saxifragaceae (*Hydrangea*, *Philadelphus*, *Rodgersia*, *Ribes*, *Escallonia*, *Bergenia*, *Deutzia* and *Heuchera*) which have been investigated so far, the occurrence of this compound seems to be of some taxonomic value.

Organic Acids of the Rhizome of *Iris pseudacorus* L.

SHIKIMIC, quinic, succinic, malic, citric, fumaric and lactic acids have been separated on 'Dowex 1' ion-exchanger from combined aqueous and alcohol extracts of *Iris pseudacorus*, using the method of Hulme and Wooltorton[1]. These acids have been identified from their elution positions, their R_F values in various solvents and by chemical tests where appropriate.

The major acid was identified as shikimic acid: (*a*) by its R_F values of 0·19 in 1-pentanol/5 *N* formic acid (1 : 1; v/v) and 0·54 in phenol/90 per cent (w/v) formic acid/water (300 : 4 : 100; w/v/v)[2]; (*b*) by co-chromatography with an authentic sample of shikimic acid (Light and Co.); (*c*) by its colour reactions with potassium permanganate[2] and with sodium metaperiodate/piperazine/sodium nitroprusside[1]; (*d*) by the similarity of its infra-red spectrum with that figured by Davis *et al.*[3] (Fig. 1).

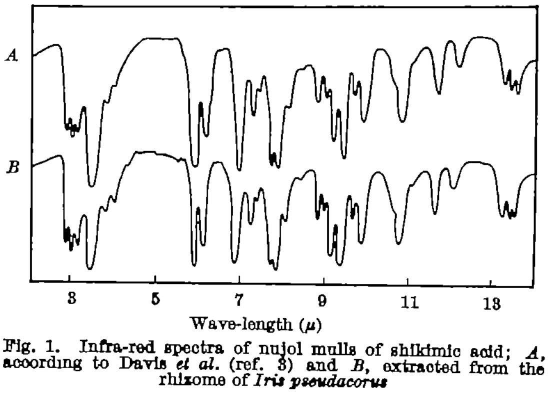

Fig. 1. Infra-red spectra of nujol mulls of shikimic acid; *A*, according to Davis *et al.* (ref. 3) and *B*, extracted from the rhizome of *Iris pseudacorus*

Table 1. Seasonal Variation in Acid Content of Iris Rhizome
(Expressed in mgm 100/gm fresh wt.)

Date	Shikimic	Quinic	Malic
Feb. 17	739	99	163
March 8	878	167	225
April 1	610	85	137
June 10	545	93	67

Table 1 shows the changes in amounts of the three principal acids, as extracted from *Iris* rhizome on four occasions during the first six months of 1960.

These results show that there is a build-up of all three acids during the late winter months, and a pronounced drop following leaf emergence. Quinic-U-^{14}C has been shown to give rise to radioactive shikimate in several higher plants[4], and the presence therefore of quinic acid in *Iris* rhizome in concentrations related to those of shikimic is of considerable interest. The importance of shikimic acid in further biosynthesis is under investigation.

Alkaline Phosphatase of *Escherichia coli* and the Inactivation of Tryptophanase

In continuation of the studies on pyridoxamine phosphate oxidase and pyridoxal phosphatase activities by *Escherichia coli*[1,2] and their significance in the control of amino-acid metabolism, we have now prepared both acid and alkaline phosphatases from extracts of the strains of *E. coli* which we are using in Leeds and examined their action on the tryptophanase system. We had previously shown that such extracts had a high acid phosphatase and low alkaline phosphatase activity, but that a mammalian acid phosphatase did not dephosphorylate pyridoxal phosphate whereas an alkaline phosphatase did[3].

The acid phosphatase from *E. coli* is without activity on pyridoxal and pyridoxamine phosphates whereas the alkaline phosphatase hydrolyses the aldehyde phosphate but not the amine phosphate. This appears to contrast with the mammalian enzyme[1,3,4].

In the extracts of *E. coli* which we are using as a source of tryptophanase, 8 mgm. of extract protein dephosphorylates approximately 20 μgm. pyridoxal phosphate in 80 min. under conditions applied in the study of the kinetics of the tryptophanase system[5]. We have consequently investigated the role of this alkaline phosphatase in the inactivation of the enzyme by ageing.

The extract (tryptophanase) has been incubated at 37° for varying periods of time in a solution comprising a 0·05 *M tris* buffer *p*H 7·8, magnesium sulphate (0·2 × 10^{-2} *M*), potassium chloride (0·05 *M*), pyridoxal phosphate or water, both with and without the alkaline phosphatase preparation. The total volume of these systems has been 2·5 ml. After the desired time, 0·5 ml. of 1·96 × 10^{-2} *M* DL tryptophan has been added and the activity of the tryptophanase assessed by the amount of indole produced during a further incubation for 5 min.

Table 1

System tested	Indole produced (μgm.) after incubation of the system for			
	0 min.	60 min.	135 min.	200 min.
Tryptophanase	11	9	2·5	2·5
Tryptophanase and phosphatase	11	3·5	1·0	1·0
Tryptophanase and Pal.P 20 μgm	52	52	50	52
Tryptophanase and Pal.P and phosphatase	45	13	2·5	2·5

Table 1 shows the results taken from a number of similar experiments in which variations in the concentration of reactants have been used.

The concentration of Mg^{++} is less than the optimum required for the alkaline phosphatase studies of Turner[3], but corresponds to that used in studies on the enzymatic conversion of pyridoxamine phosphate to pyridoxal phosphate[5,6].

The results indicated: (1) a rapid loss in activity of the tryptophanase extract due to added phosphatase; (2) that added pyridoxal phosphate which stabilizes the tryptophanase for a time against the small amount of phosphatase present in the extract is also rapidly dephosphorylated by added phosphatase. It would appear from further experiments that the combined pyridoxal phosphate in tryptophanase is protected somewhat against the phosphatase, but further kinetic studies are proceeding.

PHYSIOLOGY

Post-Operative Intra-Abdominal Adhesions

The ætiology of the persistent fibrous adhesions which may develop after an abdominal operation presents an important and as yet incompletely solved problem. The accepted view is that, in most cases, these adhesions represent the fibrous tissue laid down in the healing of raw peritoneal surfaces which may result from surgical trauma or from severe infection. The observations presented here are the results of experiments on adult rats.

Division of the mesentery of the small intestine, sufficient to impair its blood supply, resulted in adhesions which were confined to the region of the devascularized segment; the bulk of adhesion formation was roughly proportional to the length of the ischæmic bowel. Even in the presence of diffuse peritonitis, fibrous (as distinct from fibrinous) adhesions were localized to the ischæmic bowel. These adhesions were essentially nutritive; thus a sheet of fine polythene film placed around the devascularized segment to prevent the adhesions from reaching the gut wall was invariably followed by gangrene.

When the omentum with its blood supply intact was sutured as a pedicled graft around such segments of devascularized intestine, the graft would rapidly become attached to the underlying ischæmic intestine. It could then be shown by injection studies, using micro-radiography and micro-dissection methods, that these adhesions were vascular in nature and provided a graft of blood vessels to the ischæmic bowel.

In contrast, detached (and therefore ischæmic) omental grafts wrapped around similar devascularized segments of intestine had no such protective effect; in fact the extra bulk of ischæmic tissue merely provoked a tremendous adhesive reaction to adjacent healthy viscera.

Large defects produced by excision of the parietal peritoneum were found to have healed smoothly in 7 days; in contrast, meticulous repair of such raw areas precipitated adhesion formation to them presumably because of the inevitable local ischæmia which resulted from the dragging together of peritoneal flaps under tension.

Moreover, any other procedure which produced dead tissue on the parietal wall—crush injuries, tightly applied ligatures or free peritoneal grafts to parietal defects—produced adhesions to intra-abdominal viscera. Injection studies showed that these adhesions conveyed blood vessels which bridged across from adjacent healthy tissues into the devascularized area.

These experiments suggest that it is ischæmic tissue which stimulates the formation of persistent adhesions which are, at least in their early stage, essentially in the nature of a vascular graft to the devitalized zone.

The exact mechanism of the stimulus is unknown. It is not merely a foreign-body reaction and is not produced by suture material loosely stitched into the parietal peritoneum. It may prove to be a specific chemical stimulus to capillary growth produced by anoxic cells.

Intracellular Localization of Catecholamines in Tissues of the Rat

PREVIOUS work in this laboratory has shown that radioactive catecholamines are removed from the circulation and retained at or near sympathetic nerve endings[1]. This fact has made it possible to study in detail the intracellular localization of these compounds. Epinephrine was found to be stored in relatively heavy granules in the adrenal medulla[2], and in similar granules in chromaffin cells of cyclostome hearts[3]. Recent work has suggested that norepinephrine is also retained in particulate material, as yet unidentified, in splenic nerves[4,5], brain[6], and puppy hearts[7]. We wish to report that norepinephrine is predominantly localized in small particles which sediment with the microsomes.

Sprague–Dawley male rats weighing 140–160 gm. were given 50 μc. of tritiated-norepinephrine (20 mc./mgm.) intravenously, and were killed 30 min. later by a blow on the head. Tissues were removed immediately and washed in ice-cold sucrose. Homogenization in 5 vol. of isotonic sucrose was performed with a loose-fitting glass pestle for 2 min. (heart) or 0·5 min. (other tissues) in a salted ice bath.

Subcellular fractions were separated by a single centrifugation in a continuous sucrose density gradient prepared as follows. A small vertical tube containing isotonic sucrose was tightly fitted over a 5-ml. flask so as to communicate through a fine needle. The lower flask was initially filled with 60 per cent sucrose and was mixed by a magnetic stirrer. A side-arm with a fine tip at the bottom of the flask permitted slow outflow into an ultracentrifuge tube. The dilute solution dripped slowly into the flask, progressively diluting its contents and producing a gradient in the outflow varying from 60 to 10 per cent sucrose. Tissue homogenates were carefully layered on the surface of the sucrose gradients, and the tubes were centrifuged in the Spinco ultracentrifuge using an *SW*39 rotor at 35,000 r.p.m. for 30 min.

Fig. 1 shows the appearance of a sucrose gradient with heart homogenate, after centrifugation. Five distinct layers were found: a nuclear and cellular sediment on the bottom, a hazy band of muscle debris, a thin red hæmoglobin layer, a yellowish mitochondrial region, and a faintly cloudy microsomal band below the clear supernatant fluid. Approximately 70 drops were collected with a needle through the bottom of each tube, and these were analysed for tritiated and endogenous catecholamines and succinic acid dehydrogenase activity. Total radioactivity was assayed in a liquid scintillation counter; about 90 per cent of the total radioactivity was found to be tritiated-norepinephrine by specific assay[8]. Endogenous catecholamines were assayed fluorometrically, either directly or after alumina column purification[9]. Results were found to be the same by the two techniques. Succinic acid dehydrogenase activity was assayed by a modified tetrazolium dye reduction method[10].

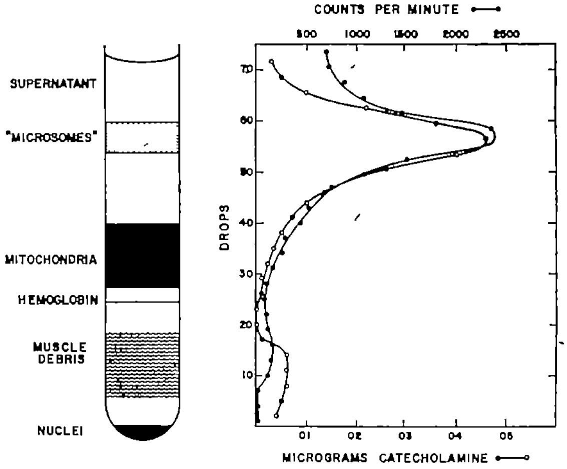

Fig. 1. Intracellular localization of tritiated norepinephrine and catecholamines in the rat heart

Fig. 1 shows the intracellular distribution of endogenous and tritiated-norepinephrine in the heart. The predominant peak of these catecholamines coincided with the 'microsomal' band. Small amounts were found in the nuclear pellet (1,092 c.p.m.) and muscle fragments. Negligible quantities were present in the mitochondrial fraction, where virtually all the succinic acid dehydrogenase activity was found. When the 'microsomal' particles from the heart were sedimented by centrifugation and then resuspended by gentle homogenization in isotonic sucrose, they retained 80 per cent of their tritiated norepinephrine. Particles suspended in water, however, lost more than 80 per cent of their ^{3}H-norepinephrine. In similar experiments, administered tritiated-epinephrine was also found in the 'microsomal' layer of the heart whereas tritiated-DOPA, tritiated-dopamine, and tritiated-normetanephrine appeared wholly in the supernatant fluid.

In the salivary glands both radioactive and endogenous epinephrine and norepinephrine were also found in the lightest particles. In the adrenal medulla most of the endogenous catecholamines and all tritiated-epinephrine and tritiated-dopamine were in heavy granules near the bottom of the tube. In contrast, tritiated-norepinephrine in the adrenal glands was predominantly found in the 'microsomal' band. Thus epinephrine and norepinephrine appear to be predominantly present in separate adrenal particles, but in the same heart particles. Tritiated-DOPA was found only in the adrenal supernatant. In the brain, radioactivity after the administration of tritiated-DOPA was found in an intermediate layer above the mitochondria, corresponding in sedimentation characteristics to the "pinched off nerve endings" studied by Whittaker[11]. Endogenous 5-hydroxytryptamine, assayed fluorometrically[12], was predominantly found in this layer as was tritiated-norepinephrine taken up by brain slices *in vitro*.

Potentiation of Narcotic Action by the Brain treated with an Electric Shock

Differences in the biological action on animals and man of homogenates from normal brains and from brains which had undergone electric shock have been shown. They take the form of pharmacological activity on sleep[1] and against phenol intoxication[2] as well as of a protective effect against neurotropic viruses[3-5] and the behaviour in clinical trials[6].

In the present work the effect of homogenates from brain subjected to an electric shock on barbiturate-induced sleep was examined in an attempt to estimate the active compounds present in them.

Hogs weighing about 100 kgm. received 15 electric shocks on alternate days and were killed one day after the last treatment. Brains were removed under sterile conditions and stored at − 20° C. until needed. Before each experiment a 10 per cent homogenate in physiological saline was prepared. Controls were made with normal brains obtained and treated under similar conditions.

Experiments were performed on rabbits of average weight 1·5 kgm. 'Evipan' (N methylcycloesenylmethylmalonylurea Bayer) dissolved in physiological saline was administered through the marginal vein of the ear as rapidly as possible. The threshold dose for immediate sleep was 15 mgm./kgm.

The period of sleep with 'Evipan' alone was first established for each animal. The effect of the administration of brain homogenates on narcosis was afterwards assayed by injecting the homogenates (2·5 ml./kgm.) into the gluteal muscles, 30 min. prior to 'Evipan'. Each animal was treated, in separate experiments, with brain subjected to electric shock and normal brain, one half the group receiving brain subjected to electric shock, the others normal brain. Three days elapsed between each treatment.

Two doses of 'Evipan' were used: a threshold dose for sleep of 15 mgm./kgm. and a larger dose of 25 mgm./kgm.

Results are given in Table 1.

Though a small increase in period of sleep is observed after administration of normal brain, little statistical significance can be given to it. On the other hand, the increase due to brain subjected to electric shock is more pronounced and significant.

Interference of effects due only to the administration of normal brain substance can be excluded, in evaluating the results, by directly comparing the results in columns III and I. It appears that the effect of substances produced in brain following electric shock treatment is particularly significant with doses of 'Evipan' larger than the limiting dose.

The presence in brain subjected to electric shock of substances acting on sleep was foreshadowed by Longhi[1], who, by instilling such brain homogenates, into the third ventricle of dogs, induced sleep immediately while he did not with homogenates from normal brain.

The substances active on 'Evipan'-induced sleep shown by the work reported here are likely to be related to those mentioned above. Little can be inferred, however, about their nature.

It can only be said that they act in very small doses: in fact 2·5 ml. of a 10 per cent homogenate correspond to only 65 mgm. dry brain substance[7,8] administered per kgm. of animal treated. Moreover, the absorption, after intramuscular injection, is slow and presumably

Table 1. Sleeping Period with and without Administration of Brain subjected to Electric Shock

Effect on the Thyroid Gland of Protracted Administration of Posterior Hypothalamic Extracts

As a follow-up of our investigations of the neurosecretory function of diencephalon[1] we have examined the effect on the histophysiology and respiratory function of the thyroid glands of rats of protracted administration of extracts of different regions of the hypothalamus and of the cortex.

Table 1. EFFECT OF EXTRACTS OF POSTERIOR HYPOTHALAMUS ON THE THYROID GLAND OF WHITE FEMALE RATS

	Treatment	Thyroid gland mgm./100 gm.	*P*	Acinar cell height*	*P*	K^{131}I intake (24 hr.)†	*P*
(I)	Rat cortex (10)	9·70 ± 0·43	< 0·01	5·04 ± 0·17	>0·05	—	—
	post. hypoth. (10)	13·41 ± 1·09		5·95 ± 0·54			
(II)	Cattle cortex (11)	11·37 ± 0·26	= 0·01	4·85 ± 0·14	< 0·01	—	—
	post. hypoth. (4)	18·10 ± 2·48		6·65 ± 0·55			
(III)	Rabbit cortex (8)	10·61 ± 0·50	< 0·01	—	—	31·51 ± 2·42	= 0·02
	post. hypoth. (7)	14·07 ± 0·71				22·66 ± 2·50	

(I) 0·1 per cent extract; daily dose, 1·0 ml.; length of treatment, 14 days.
(II) Filtrate of 25 per cent homog.; daily dose, 1·0 ml.; length of treatment, 14–26 days.
(III) Extract containing 1/6 of posterior hypothalamus for one day. Length of treatment, 14 days.
* In units of ocularmicrometer 100 cell/thyroid gland.
† Activity of 10 mgm. tissue of thyroid gland in per cent of injected activity.

Daily administration for at least a fortnight of a physiological saline extract obtained from the posterior hypothalamus of rats, cattle and rabbits increased, statistically significantly, the weight of the thyroid gland of white adult female rats, kept on a standard mixed diet. This effect was not obtained by administration of saline extracts of the cortex. Quantitative examination of the height of thyroid acinar cells has shown an increase which was in the second experiment significant and in the first nearly so. The administration of an extract obtained from the anterior or medial part of the hypothalamus did not produce such a reaction. The increase of weight of the thyroid gland is not accompanied by an increased ability to concentrate iodine, and even the intake of radioactive iodine in 24 hr. is, referred to the unit of weight, lower than in the group treated with cortical extract (Table 1). The administration of posterior hypothalamic extracts, after previous treatment with thyrotropic hormone ('Ambinon'), impeded the decrease in weight of the thyroid gland to the normal size. The decrease in the height of acinar epithelium was moderately influenced by this treatment. Changes in the thyroid gland induced by previous treatment with 4-methyl-2-thiouracil (a 0·15 per cent diet for 15 days) were not influenced significantly by administration of a suspension of the posterior hypothalamus.

Administration of prepared suspensions of the brains of old rats (0·8 per cent), continued for a fortnight, did not cause any difference in the function of the thyroid gland. Treatment of infantile rats with a suspension of posterior hypothalami of rats (a daily dosage of an animal containing one-third of the posterior hypothalamus) for six days resulted in narrower acini which contained less colloid and had a higher epithelial lining as compared with the group treated with a cortical suspension. The increase in height of the acinar cells and the decrease of the acinar diameter is equally significant ($P<0\cdot01$, $P<0\cdot05$). In this experiment there was no difference in weight.

A systematic investigation of supposed diencephalic neurohumoral mediators affecting the thyroid gland has been initiated by other authors[2–5]. Ottaviani and Azzali[5], having injected a lipoid fraction of diencephalic extracts of cattle into dogs and hamsters for a variable period, noted in the case of low doses a histological picture which signified an increased secretory activity of the thyroid gland, and in the case of high doses a colloid storage. Shibusawa *et al.*[6] isolated from the raw extract of the urine an active thyroid-stimulating hormone, thought to be of anterior hypothalamic origin; and Schreiber *et al.*[7] demonstrated a hypothalamic factor, increasing the acid phosphatase activity of the thyreotrophic cells of the anterior pituitary.

Our own results indicate a hypothalamic factor appearing to be concentrated in the posterior hypothalamus, affecting the function of the thyroid even of infantile animals, which, however is considerably decreased or has even disappeared in old rats. From these results it may be supposed that this hypothalamic factor is distinguished from the TRF demonstrated by Shibusawa *et al.* not only by its localization but also by the fact that it decreases the intake of iodine simultaneously with increasing the weight of the thyroid gland. We do not think it likely that an effect which would primarily aim at the cortex of the adrenal gland would be based on adrenocortical-thyroid antagonism, because we have observed some adrenocortical stimulation only after administration of more concentrated anterior hypothalamic extracts without changes in the thyroid gland. At present we venture to suppose an inhibitory effect which seems to be similar to that of goitrogenic agents.

Bovine Bracken Poisoning

WHILE preparing a blood smear for the differential leucocyte count, it is found that the blood of cattle in the terminal stages of bracken poisoning does not spread evenly in the manner of a normal sample, but presents a blotched or streaky appearance[1] (Fig. 1). Bracken plasma contains increased amounts of fibrinogen[2], but streaking is not produced if commercial bovine fibrinogen is added to normal blood, to give equivalent concentrations[3]. Nevertheless, we have established that the streaking is connected with the fibrinogen, and have reason to suppose that a small, altered fraction is the cause. Ultracentrifuge readings suggest that since this fraction runs more rapidly, it has a larger molecular weight than the main body of fibrinogen which runs normally (Fig. 2).

Many references in the literature[4-6] indicate that heparinoid substances of large molecular weight with sulphated groups and strong negative charge have an affinity for fibrinogen, forming reversible polymers. (Compare the behaviour of polysaccharides containing sulphuric acid esters with dye molecules and the resulting metachromasia[7].) These abnormal fibrinogens have a tendency to be cold-insoluble and are often connected with a higher erythrocyte sedimentation-rate. They increase in amount in certain disorders notably of a rheumatic or febrile nature[5,8]. These considerations and the fact that the blood of irradiated rabbits contains increased amounts of heparin[9] led us to follow the blood heparin-levels in a calf with experimentally-induced bracken poisoning, the results obtained being positive with a terminal increase (Fig. 3). The release of heparin in abnormal amounts into the circulation suggests an involvement or destruction of body mast cells. Since these cells also store histamine, it is reasonable to suppose that this toxic amine may also be present in increased

Top, ○, Leucocytes × 10^3/mm.^{3}; ×, platelets × 10^5/mm.^{3}; ●, neutrophils (percentage of differential count); *B*, 2·5 per cent basophils in differential count.

Middle, ●, Fibrinogen (optical density at 540 mμ × 10^{-1}); ×, erythrocyte sedimentation-rate (mm. per 24 hr.); ○, blood heparin-level (γ's protamine sulphate × 10, required to clot blood); *, incoagulable with 35 γ-protamine sulphate. Injections: (1) 250 mgm. toluidine blue in 250-ml. saline (intravenous); (2) 150 mgm. 'Anthisan', 500 mgm. batyl alcohol dispersed in physiological saline by 'Tween' 20 and 80, 18 mgm. 'Predsolan' (intramuscular); (3) 250 mgm. toluidine blue in 250 ml. as before, 150 mgm. 'Anthisan' (intramuscular); (4) 100 mgm. 'Anthisan', 700 mgm. batyl alcohol (intravenous); 20 mgm. 'Predsolan' (intramuscular), 4 ml. 'Distavone' (intramuscular); (5) 4 ml. 'Distavone' only (intramuscular).

Bottom, ·——·, Temperatures (° F.) morning and evening; *S*, blood smears begin to show irregular streaking quantities in a biologically active form[10]. Our present experiments are directed to test this theory. An increase in free heparin and histamine would help to explain the prolonged clotting-time and increased capillary fragility known to accompany bracken poisoning.

In spite of lack of definite knowledge about histamine-levels, we tried the following combined therapy: (1) Toluidine blue, intravenous (anti-heparin); (2) 'Anthisan', intramuscular (anti-histamine); (3) 'Predsolan', intramuscular (hydrocortisone treatment); (4) batyl alcohol, intravenous (bone marrow stimulant); (5) 'Distavone', intramuscular (precautionary antibiotic indicated by leucopenia). (The dosages and time-intervals were purely experimental and both these and the use of cortisone treatment and 'Tween' will obviously be open to revision.)

The recovery of the five-month-old calf, together with clinical records and details of the therapy, are given in Fig. 3. Two field cases of four-month-old calves have also responded to this treatment. It should be pointed out that recovery of calves of this age from acute bracken poisoning is rare.

Since bracken poisoning is a radiomimetic condition, we suggest that these findings may be relevant to irradiation sickness. It would be interesting to know if a combined therapy of this nature would give similar hopeful results. One of us (I. A. E.) thanks the Agricultural Research Council for support and R. M. H. acknowledges a Ministry of Agriculture, Fisheries and Food postgraduate studentship. We thank Mr. J. T. Bowen, Department of Biochemistry, University of Leeds, for carrying out the ultracentrifuge runs.

HISTOLOGY

Histology of Omental Reactivity

Comparative histological examinations of the greater omentum have shown that the characteristic 'milk spots' of the human omentum are an equally constant and striking feature of this membrane in the pig but appear to be absent in dog and cat. These structures have been examined in whole spread preparations of human and pig material stained with Weigert's hæmatoxylin, Mallory and toluidine blue for cytological detail and by the Falgog method[1] for the vascular pattern.

In both species the spots consist of a thin reticular capsule and stroma, densely packed with cells and traversed by two or more blood-vessels which form a glomus-like network within the cellular mass.

In man, the cells of the milk spots are predominantly mature lymphocytes. In the pig, lymphocytes are replaced by large, pale-staining multi-nucleolated cells intermingled with plasma cells in a pattern essentially similar to the germinal centre of the lymphoid nodule. The very numerous mast cells distributed along the omental blood-vessels showed much the same abundance in man and in the pig.

Two preliminary types of experiment have been carried out in the pig: one, the induction of shock by traction on the omentum, and the other, the production of hæmorrhage in the peritoneal cavity by puncture of a gastro-epiploic vein. Traction shock produced a drop in the total apparent mast cell population. This was accompanied by an extrusion of the large, basophilic granules from approximately 40 per cent of the remaining mast cells. Intraperitoneal hæmorrhage produced a similar drop in the total apparent mast cell population and diffusion of the metachromatic intergranular substance from approximately 70 per cent of the remaining mast cells into the surrounding tissue.

Roberts[2] stated that antigen injected into the peritoneal cavity is taken up by the milk spots of the omentum and the draining lymph nodes. More recently, Walker and Rogers[3] have described the role of the rabbit omentum in antibody synthesis.

The experimental findings outlined here appear to throw some further light on the known reactivity of the omentum to trauma.

Further investigations are proceeding along two lines, namely, the significance of the glomus-like formations already mentioned and the histochemistry of the reactions which have been described.

The work is supported by a part-time fellowship Grant from the Medical Research Council of Ireland.

Staining Characteristics of Chromaffin Granules in Human Skin

Reports of the presence of chromaffin cells in human skin[1-3] are of importance, because this work could, if confirmed, open a new concept in the control of the peripheral circulation[4]. Changes have been found to occur in these cells in the cat's tail and nictitating membrane after reserpine and denervation which could indicate their association with the sympathetic system[5]. Burn and Rand[6] have further suggested that these cells might be the site of storage of noradrenalin in the sympathetic post-ganglionic mechanism.

Adams-Ray and Nordenstam[1,2] and Burch and Phillips[3] have emphasized the superiority of the Sevki stain (a modified Giemsa stain) for demonstrating red chromaffin granules in chromated skin. However, using similar techniques, Mercantini[7] found it impossible to differentiate mast cell granules staining purple or bluish-red from other granules staining clear-red or bluish-red presumed to be chromaffin granules. To support their claims that a red colour indicates chromaffinity Adams-Ray and Nordenstam[1,2] have referred to Pearse[8], but have, in addition, reported the same reaction in adrenal medulla treated identically. However, Pearse[9] states that the Sevki method applied to chromated tissue produces not a red colour but a green colour in the presence of adrenalin or noradrenalin. Also, Coupland[10] found that the Giemsa stain after formal dichromate fixation produced a green colour in adrenal medullary cells.

We have confirmed that the brown chromaffin substance in chromated adrenal medulla (Orth's solution) turns green when stained with the Sevki technique of Burch and Phillips[3]. This green colour in mouse adrenal was greatly reduced by previously treating the animal with reserpine.

We are unable to suggest why the previous investigators[1-3] did not find a green colour in adrenal medulla using similar techniques.

We have proceeded to examine fresh chromated human skin for the presence of chromaffin-positive granules which might turn green on staining with Sevki's method. The only cells producing a brown colour in the dermis were dermal chromatophores and red blood cells. The natural colour of the pigment in chromatophores was indistinguishable from that produced by a true chromaffin reaction whether or not the skin was chromated. These chromatophores frequently had bipolar cytoplasmic projections containing granules of variable size. On staining with the Sevki method the pigment in chromatophores frequently developed a green tinge whereas the brown chromaffin-positive red blood cells remained unchanged.

Many elongated cells with fine red granules, described by others to be chromaffin cells, were seen in the Sevki-stained sections. However, there was no suggestion of a green colour in these cells, which indicated that the granules were unlikely to contain adrenalin or noradrenalin.

Since mast cell granules stain in an identical manner and both these and 'chromaffin cell' granules are metachromatic with toluidine blue, we suggest that, despite differences in morphology, the 'chromaffin cells' in human skin are mast cells.

From these observations we conclude that if the post-ganglionic transmission theory of Burn and Rand[11] applies to human skin, the peripheral stores of noradrenalin are unlikely to exist in the 'chromaffin cells' described by Adams-Ray and Nordenstam.

HISTOCHEMISTRY

Immunohistochemical Localization of Drug-binding Protein in Tissues of the Electric Eel

A PROTEIN having a high affinity for *d*-tubocurarine has been isolated from ammonium sulphate fractions of extracts of electric organ of electric eel[1,2]. Although *d*-tubocurarine combines with a variety of macromolecules[3-5], the reaction with the electric organ protein appeared to be somewhat unique, especially since the resulting complex is very stable to high ionic strength[1]. The protein also combines in a more or less specific way with a large number of neurotropic compounds, the relative affinities in general paralleling the effectiveness of these compounds in their pharmacological action upon the single isolated electroplax[1,2,5,6] and squid giant axon[7,8]. Although it was proposed[1,2] that the protein might function *in vivo* as a 'receptor' for acetylcholine and other neurotropic compounds, more recent evidence has led to a suggestion of an entirely different role[9,10], namely, that the protein might be the drug-binding component of conducting membranes only and thus is not involved in the physiological effects of acetylcholine and other depolarizing agents. The distribution of this material in the electroplax is thus of primary importance in determining whether or not the conclusions regarding its proposed biological significance are justified.

The high solubility of the protein in aqueous solution, the fact that it does not gel on heating, and its antigenic properties (as described here), indicate that it most likely is not a component of connective tissue fibres. The protein contains a significant amount of phospholipid, primarily in the form of lecithin, and this suggests the possibility of a membranous origin. One method for rather precise localization of the protein is by means of the fluorescent antibody technique, the results of which are reported in this communication.

Rabbit antiserum was prepared to an alum precipitate of the purified protein and used as an immunohistochemical reagent. Pooled antisera were first subjected to sodium sulphate fractionation to obtain a crude globulin fraction. This was tested against the original protein antigen by the Ouchterlony gel diffusion method which revealed the presence of two bands, one of far greater intensity than the other. This finding correlates with results of free electrophoresis and ultracentrifugation, both of which showed the presence of a 10 per cent impurity in the preparation[11]. The crude globulin was then conjugated with a fluorescein derivative according to the method of Coons and Kaplan[12]. After appropriate absorption and dilution procedures, the fluorescein-labelled antibody was used as a (specific) stain for the detection of the original antigen (receptor protein) in frozen sections of various electric eel tissues, including single isolated cells (electroplax) from the main organ. After staining, sites at which the protein is present were rendered visible as areas of bright green fluorescence under the fluorescence microscope. Specificity of staining was established by conventional means including the demonstration of: (1) inhibition of tissue staining by pre-treatment with unlabelled antibody; (2) failure of tissue staining by a fluorescein-globulin preparation with unrelated or no antibody activity.

When sections of single eel electroplax were examined by this method, the receptor protein was found to be present in, or in close proximity to, both

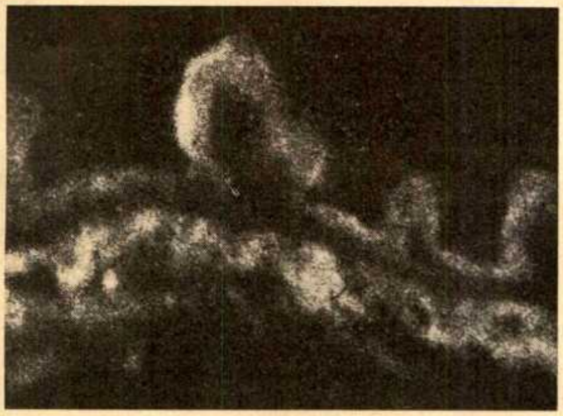

Fig. 1. Localization of drug-binding protein in the electroplax of electric eel. Areas where the protein is present are white. Specific staining may be seen at both the innervated (bottom) and non-innervated membrane (top), as well as in the loose connective tissue on the innervated side

the innervated and non-innervated membranes (Fig. 1). No protein could be demonstrated in the cell interior. In these sections, there appeared to be some specific fluorescence in the region of the nerve supply to the electroplax. Interestingly, prior application of either *d*-tubocurarine or protamine, both of which precipitate the protein *in vitro*, failed to reduce the intensity of tissue staining, suggesting that the drug combining sites and antigenic sites of the protein are distinct. This finding was confirmed in test-tube experiments, that is, neither *d*-tubocurarine nor protamine reduced the amount of receptor-antibody precipitate.

In other work using the fluorescent antibody technique[13], receptor protein was found to be absent in eel serum and in eel red blood cells. In eel muscle, it was found in the form of a fine trabecular network which surrounds and enmeshes muscle fibres. Muscle sarcolemma and muscle cell interior do not contain the protein. There was no observable difference in the pattern of staining in muscle which had previously been denervated. Heart muscle stained in a manner similar to that described for skeletal muscle. The protein could not be demonstrated in nerve cell bodies or in heavily myelinated axons. It was found, however, in the form of a membrane surrounding vagus nerve fibres.

Skeletal muscle and heart taken from other species did not stain with the fluorescein-tagged antibody, thus confirming the specificity of the reaction with electric tissue component.

These results point to a sharply localized and apparently characteristic distribution of this drug-binding protein in excitable tissues; together with the somewhat unique *in vitro* properties of this material, they strengthen the suggestion for an *in vivo* role in neurophysiological processes. However, the weak binding of acetylcholine and other potent depolarizing compounds, for example, decamethonium, carbamylcholine, etc., together with the fact that the protein is in or near both the innervated and non-innervated membranes of the electroplax, constitute difficulties in assigning to this protein the function of physiological acetylcholine receptor substance of the end-plate region. The present results would appear to strengthen the newer hypothesis[9,10] that the protein may serve as a model for the component of conducting membranes of electroplax and squid axon with which drugs in general combine when they exert their actions on these systems. On this basis, the weak actions of acetylcholine, decamethonium, carbamylcholine, prostigmine and eserine, on specially treated nerves, for example, cobra venom[8], or cationic detergent[14], are predicted, as is the much greater effectiveness of *d*-tubocurarine, chlorisondamine and protamine under similar circumstances.

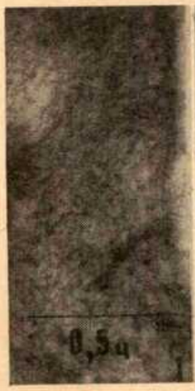
PATHOLOGY

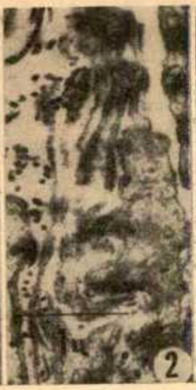
Fine Structure of Tumour Stroma and Blood Vessel Stroma in Human Supratentorial Meningioma

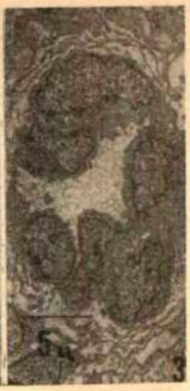
Meningiomas generally provoke a higher degree of vascular proliferation than do other benign tumour cells. Vascularization in the different meningioma groups is in some respects similar to, in others different from, the vessel systems in the respective tissue of origin.

The material used consisted of samples of supratentorial meningioma and tissue of origin, that is, dura and arachnoidea, from 14 patients and samples of normal cerebral tissue containing blood vessels from 5 patients with other brain diseases. The specimens were fixed in osmic acid, stained with phosphotungstic acid or uranylacetate and embedded in methacrylate and araldite. Ultra-thin sections were cut on a Porter–Blum microtome and examined with a Philips *EM* 100 *B* electron microscope. The material was also analysed with a light microscope, using different connective tissue stains.

Electron microscopic examination of the vessels in endotheliomatous meningiomas showed an abundance of structures generally formed of polysaccharides. Basement membranes could be seen in nearly every border area between endothelial cells, connective tissue processes and perivascular cells. Basement membranes were seen even within the connective tissue processes (Fig. 2) and in the cytoplasm of endothelial cells (cf. ref. 1). In the larger vessels the







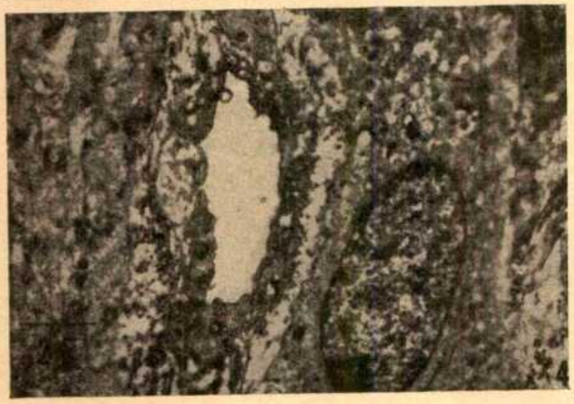


Fig. 1. Collagenous microfibrils in endothelium of vessel wall in a sphenoidal, fibromatous meningioma. (× 40,500)

Fig. 2. Basement membranes in connective tissue processes of vessel wall in a parasagittal, endotheliomatous meningioma. (× 15,200)

Fig. 3. Proliferation of endothelium of a capillary in an angiomatous meningioma. (× 1,800)

Fig. 4. Arteriole in an endotheliomatous meningioma of tuberculum sellæ. The number of collagen fibrils per area unit of ground substance is nearly the same in the vessel stroma (centre) as in the tumour stroma (right). (× 4,800)

amount of ground substance in the walls was more important in relation to the frequency of collagenous and reticular fibrils in the substance than in the vessel walls of fibromatous and angiomatous meningiomas. The periodicity of the collagen was about 640 Å. The breadth of the basement membranes was generally 500–1200 Å., but thicknesses of up to 2000 Å. could be observed. It has been emphasized[2] that meningiomas in their degenerative state, and especially as cysts, are rich in polysaccharides, and that the process of regression starts from the basement membranes.

Fibromatous meningiomas closely associated with the dura generally showed a sparser vascular network than the endotheliomatous meningiomas. The endothelial cells and the connective tissue layers in the vessel walls of fibromatous meningiomas contained bunches of microfibrils (Fig. 1). It is possible that these microfibrils mark a stage in the homogenizing collagenosis of vessels, typical of these meningiomas. The elastin frequently was situated peripheral to this layer, and collagenosis probably had begun from the inside of the vessel (cf. ref. 3). The elastic fibres had a very 'looping' course, but they were of normal fine structure. In the light microscopic examination this 'looping' elastin had a 'granular' appearance in cross-section. In the electron microscopic examination the number of collagen fibrils per area unit of ground substance was much greater in the tumour stroma than in the stroma of vessel walls. This relation was the same in the tissue of origin, that is, in the dura. In the endotheliomatous meningiomas the number of collagen fibrils per area unit of ground substance was nearly the same in the vessel walls, in the tumour stroma and in the tissue of origin, that is, the arachnoidea, of the same cases (Fig. 4). The periodicity of all collagen fibrils was the same in fibromatous and endotheliomatous meningiomas.

In the angiomatous meningiomas the blood vessels showed a high degree of endothelial proliferation (Fig. 3). Total obliteration of the vessels has been stressed as a contributing factor in the calcification process which is typical of this tumour[3]. Vascular dilatation was frequently observed. Dilated vessels have been seen even in the normal subdural appendicular vessel layer[2]. The number of fibrils per area unit of ground substance in the angiomatous meningiomas and in the subdural appendicular vessel layer in the same cases was greater in the vessel stroma than in other tissue stroma. The periodicity of collagen was the same as in other types of meningiomas.

The present findings seem to confirm the mesenchymal origin of all meningioma types as well as to clarify some reasons for the type of regressive alterations in meningiomas.

Urethan Induction of Thymic Lymphoma in *C57bl* Mice

URETHAN (ethyl carbamate) has been reported to augment the induction of lymphoid leukæmias by X-ray, œstrogen or methyl cholanthrene[1]. Since urethan alone did not augment the incidence of tumours in these low-leukæmia strains, it was suggested that it be classified as a 'co-leukæmogen'. The drug has not been found to affect the incidence of leukæmia in the high-leukæmia *AKR* and *C58* strains[2], and it has caused only a slight shortening of the latent period in them. However, in Swiss albino mice injected at birth[3,4], as well as in adults given toxic amounts of the drug in the drinking water in two divided 10-day intervals[5], there has been a moderate augmentation of leukæmia incidence and shortening of the latent period. Untreated mice of this strain have a fairly low incidence of leukæmia that is influenced by the sex. Berenblum and Trainin[6] found that urethan augmented leukæmogenesis by X-ray in the low-leukæmia *C57bl* strain only if it was given during or after the X-ray treatment. They have presented evidence that the tissues of *C57bl* mice immediately after irradiation contain a factor which, together with urethan, augments the incidence of leukæmia in this (low-leukæmia) strain[7]. This factor was not found in the tissues of non-irradiated mice but it was still present in the tissues 30 days after irradiation. They suggest that urethan acts as a 'promoter' in a two-stage mechanism that implies the necessity of an 'initiating' factor.

The radiation-induced leukæmia of *C57bl* mice has been shown to arise in the thymus[6]. This communication reports the induction of thymic lymphoma in 12 out of 13 *C57bl* mice surviving repeated toxic dosages of urethan alone. The stock of mice was obtained from the Texas Inbred Mouse Company, Houston, Texas. The incidence of thymic lymphoma in untreated mice in this colony is 3 per cent at 15 months of age (Dmochowski, L., personal communication).

Urethan was injected subcutaneously into mice less than 24 hr. old at a dose of 1 mgm./gm. body-weight. Seven further injections at the same dose were given at weekly intervals. The young were separated from their mothers for the period of anæsthesia following injection. Despite this precaution, a high mortality was observed, due in part to maternal cannibalism. Thirteen animals survived the injection series, although one dying at 10 weeks of age was too autolysed for histological examination, leaving a total of 12 determinate mice. Tumours were found in all twelve of these at autopsy (Table 1) between 12 and 27 weeks of age. The mean age (17 weeks) at which tumours were discovered was considerably less than the mean latent period (24 weeks) reported for the radiation-induced lymphoma in this strain[9]. We have observed no lymphoid tumours in 30 untreated animals in this laboratory followed to about one year of age.

Table 1. INCIDENCE OF THYMIC LYMPHOMA IN URETHAN-TREATED *C57bl* MICE

				Tumour-bearing mice	
litter No.	No. of mice	Died during treatment	Net No. of mice	No.	Mean age (weeks)
1	7	3	4	4	16
2*	7	3	3	3	20
3	4	3	1	1	12
4	6	2	4	4	15
Total	24	11	12	12	(av.)17

* One animal in this litter died at 10 weeks without histological examination.

The tumours were indistinguishable histologically from the thymic lymphoma which is induced by irradiation in this strain[8]. However, the pattern of dissemination (Table 2) was not identical to that reported for the radiation-induced thymic lymphoma. Dissemination was found in 7 of the 12 animals (58 per cent). Sections of thymus, lymph nodes, lung, liver, spleen, kidney, testis and small intestine were examined routinely. A noteworthy absence of identifiable dissemination to the spleen may be a result of the early deaths.

Table 2. DISTRIBUTION OF LYMPHOMA IN TUMOUR-BEARING MICE

		Local spread	Dissemination			
	Thymus	Mediastinum	Liver	Lung	Kidney	Lymph nodes
No. examined	12	12	12	12	8	9
No. with tumour	12	9	6	5	3	2
Per cent with tumour	100	75	50	42	37·5	22

We have also injected *C57bl* mice intraperitoneally with the same dose of urethan beginning between 4 and 5 weeks of age and continuing weekly for a total of 4 treatments. Of 19 mice receiving this treatment, and followed to one year of age, only one developed lymphoma at 10 months.

It is apparent that urethan administered to newborn *C57bl* mice will induce thymic lymphomas with a frequency approached only by that following divided doses of whole body X-irradiation. It remains to be shown whether urethan acts directly on the thymus as the initiator of these tumours or whether its effect, like that of X-rays[10], is indirectly mediated. It may be significant that urethan has been shown to affect mitosis and maturation of bone marrow cells[11] and that it abolishes the protection of bone marrow shielding against radiation-induced thymic lymphoma[1].

Lipid Content in Hyperdiploid and Hypertetraploid Cells isolated from the Hyperdiploid Ehrlich Ascites Tumour

THE hyperdiploid Ehrlich ascites tumour, described by Hauschka *et al.*[1], contains about 5 per cent hypertetraploid cells. A varying amount of non-tumour cells (leucocytes) always occurs. By counter-streaming centrifugation a fraction of hyperdiploid cells could be obtained free from hypertetraploid cells which were concentrated into another fraction[2]. Inoculated into another mouse this fraction developed into a tumour with a higher proportion of hypertetraploid cells than the original one. Repeated fractionation followed by inoculation of this fraction increased the mean number of chromosomes per cell to about twice the original one, the mean number of chromosomes being estimated as the amount of deoxyribonucleic acid phosphorus (DNAP) per cell.

The hypertetraploid cells with a volume twice that of the hyperdiploid ones could be expected to have the highest relative sedimentation-rate of all the cells of the tumour. Nevertheless at counter-streaming centrifugation they behave as if they were smaller or specifically denser than the hypderdiploid cells. When investigating the reason for this unexpected distribution it was observed that small structures, previously referred to as 'vacuoles'[3] and occurring on the surface as well as in the interior of the tumour cells, are more abundant in large than in small cells[2]. These vacuoles are spherical, are strongly refractive, stain intensely black when treated with sudan *B* according to Baker, and Chiffele and Putt[4], and are thus made up of lipids. Accordingly their specific density is low as appears from the fact that, when liberated from the surface of the cells by handling of the suspensions, they accumulate on the top of the supernatant on prolonged centrifugation (cf. also ref. 5).

Fairly pure suspensions of hyperdiploid and hypertetraploid cells were prepared as previously described[2]. DNAP was analysed by Schneider's method[8]. DNAP/cell varied slightly around $1\cdot00 \times 10^{-6}$ μgm. for the hyperdiploid and about $2\cdot00 \times 10^{-6}$ μgm. for the hypertetraploid suspensions. Total lipids were extracted with alcohol ether mixture by Bloor's method[6], and analysed for different fractions of lipids the amounts of which are referred to 1·0 μgm. DNAP (Table 1). As the volumes of the two kinds of cells are proportionate to their contents of DNAP, the figures obtained may be looked on as amounts per unit cell volume. It appears that the amount of 'total lipid fatty acids and cholesterol' is more than twice as great in the hypertetraploid cells as in the hyperdiploid ones. About half the difference is due to cholesterol, the other half being due to fatty acids. Although the amount of cholesterol is about four times higher in the hypertetraploid than in the hyperdiploid cells, the relationship between free and esterified cholesterol is the same. The amount of phospholipids is, however, only slightly higher in the hypertetraploid cells than in the hyperdiploid ones.

Table 1. LIPID FRACTIONS IN HYPERDIPLOID (6 SAMPLES) AND HYPERTETRAPLOID CELLS (7 SAMPLES) IN μGM. PER μGM. DNAP

	Total lipid fatty acids and cholesterol*	Total lipid fatty acids†	Phospholipids*	Free cholesterol‡	Total cholesterol‡
Hyperdiploid cells	22·0	12·0	9·3	1·7	3·7
Hypertetraploid cells	47·9	21·9	11·3	8·4	16·3

* Analysed according to Bloor (ref. 6).
† Analysed according to Stoddard and Drury (ref. 6).
‡ Analysed according to Schoenheimer and Sperry (ref. 7).

Analyses of lipid fractions in tetraploid and octoploid ascites tumour cells of other origin are being made.

The reported results suggest a lower specific density of the hypertetraploid than of the hyperdiploid cells. It is furthermore obvious that doubling of the chromosome number induces a remarkable change in the lipid metabolism.

IMMUNOLOGY

Use of Ferritin-Conjugated Antibody to identify Nephrotoxic Sera in Renal Tissue by Electron Microscopy

EXPERIMENTAL acute glomerulonephritis is readily produced in rats by the injection of rabbit antibody into rat kidney[1]. It has been found by radioautography that labelled nephrotoxic antibody was present in glomeruli[2]. Investigations with the fluorescent antibody technique afterwards showed the deposition of nephrotoxic globulin in what appeared to be basement membranes[3,4]; but lack of resolution made precise localization difficult.

The conjugation of ferritin with globulin[5] has now provided a method for detecting the sites of antigen–antibody reaction within cells by means of electron microscopy[6]. The purpose of this communication is to report the use of this technique for the precise localization of nephrotoxic globulin.

Following injection of rabbit antibody against rat kidney, the rats were lightly anæsthetized and the kidneys removed. Very thin pieces of cortex were excised and fixed for 1 hr. at 4° C. in 5 per cent formalin phosphate buffered at *p*H 7·2. In view of the injury to fine structure caused by freezing, it was decided to facilitate the penetration of ferritin by cutting the tissue into very small fragments under a dissecting microscope at 4° C. These fragments were then immersed for 20 min. at room temperature in ferritin-conjugated antibody to rabbit globulin. (The antiserum was produced in the duck and conjugated with ferritin as previously described[5,7]. Before use it was absorbed with acetone-extracted, dried rat and mouse liver powders successively.) After a thorough washing in Tyrode's solution the tissue was fixed in osmium tetroxide, dehydrated in graded dilutions of ethyl alcohol and embedded in methacrylate. Sections 0·25μ thick were cut on a Porter–Blum microtome, and the glomeruli identified in a phase-contrast

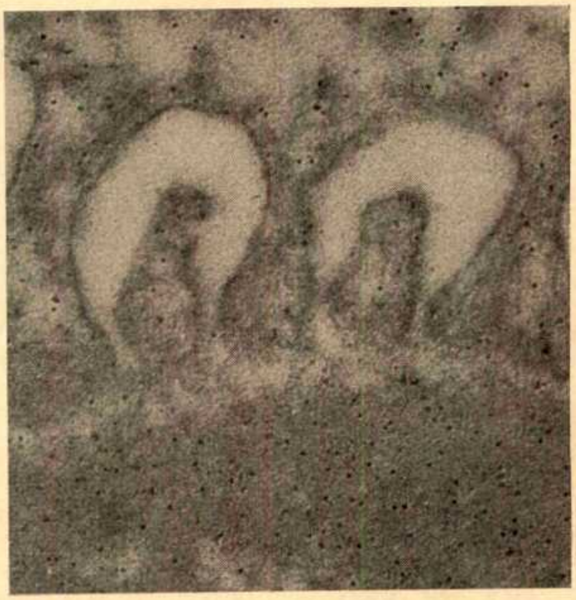

Fig. 1. Glomerular capillary wall of a rat kidney 10 days after intravenous injection of 0·8-ml. rabbit anti-rat kidney serum. The tissue was immersed in ferritin-conjugated antibody against rabbit globulin. Ferritin granules in the basement membrane and in the epithelial cytoplasm indicate the presence of the nephrotoxic rabbit globulin. (× 77,000)

microscope. The block was then trimmed so that the glomeruli could be thin-sectioned for electron microscopy.

Fig. 1 illustrates part of a glomerular capillary wall from a nephritic kidney treated with ferritin-conjugated duck antibody to rabbit globulin. The basement membrane occupies the lower third of the field, the cytoplasm of an epithelial cell with characteristic 'foot-processes' the upper two-thirds. Numerous dense ferritin granules are present within the basement membrane as well as the epithelial cytoplasm. Ferritin was also encountered in the cytoplasm of the endothelial cells (not shown in Fig. 1). There was no ferritin in the nuclei.

The specificity of the reaction of ferritin-conjugated antibody with rabbit globulin was determined by the following experiments. Pretreatment of the tissue with unconjugated duck anti-rabbit-globulin blocked subsequent tagging with ferritin-conjugated duck anti-rabbit-globulin. Purified ferritin alone and ferritin-conjugated antibody against influenza virus failed to localize in the glomerular capillary walls. Finally, specific ferritin-conjugated antibody to rabbit globulin did not tag normal rat kidney.

These results reveal that in nephritic rat kidneys the injected antibody is localized not only in the glomerular basement membrane but also in the cytoplasm of the epithelial and endothelial cells. The technique which has thus been developed should have application to many problems concerned with diseases originating from antigen–antibody reactions in tissues.

RADIOBIOLOGY

Changes in Metabolic Activities of Hepatoma Cells following Increasing X-Ray Doses

IT has been reported that ærobic and anærobic glycolysis in the Yoshida ascites sarcoma are markedly impaired following *in vitro* irradiation with a dose of 20 kr. of X-rays. In these conditions uptake of oxygen is slightly decreased[1]. A lowered incorporation of alanine labelled with carbon-14 into protein of the ascites-sarcoma cells was also noted under anærobic conditions[2]. More recently the *in vitro* irradiation of Ehrlich ascites tumour cells with different doses of X-rays (20–300 kr.), was found to stimulate both oxygen consumption and ærobic glycolysis whereas anærobic glycolysis decreased as the X-ray dose increased up to about 200 kr. (ref. 3).

Preliminary experiments in this laboratory showed that *in vitro* X-irradiation with a dose of 20 kr. did not affect ærobic glycolysis and oxygen consumption but led to a marked inhibition of anærobic glycolysis in the Yoshida ascites hepatoma cells. The incorporation of labelled glycine into protein was impaired under anærobic but not under ærobic conditions. Further investigations dealt with the effect of increasing doses of *in vitro* X-irradiation on respiration, glycolysis and incorporation of labelled leucine into protein of ascites-hepatoma cells.

The experiments were carried out as follows: well-packed ascites cells, freed from blood elements, were resuspended 1 : 15 (v/v) in ice-cold medium. In glycolysis experiments, the Ringer phosphate-bicarbonate used for resuspending the cells contained sodium chloride 108 m.mole; potassium chloride 4·7 m.mole; calcium chloride 1·3 m.mole; magnesium sulphate 1·2 m.mole; sodium-phosphate buffer, *p*H 7·4, 5 m.mole; sodium bicarbonate 26·6 m.mole. When uptake of oxygen was studied, Ringer phosphate buffered solution contained: sodium chloride 139 m.mole; potassium chloride 5·5 m.mole; calcium chloride 1·0 m.mole; magnesium sulphate

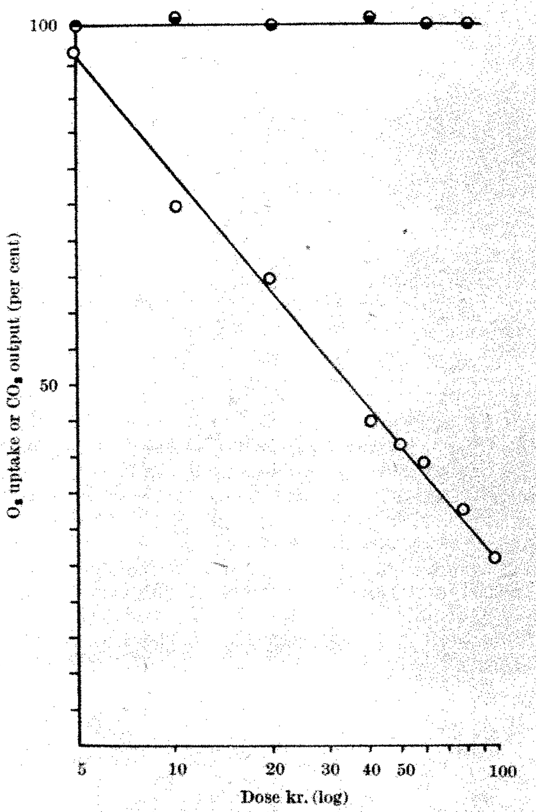

Fig. 1. Effect of increasing doses of X-rays on uptake of oxygen and anærobic glycolysis of the Yoshida ascites-hepatoma cells. ○, Anærobic glycolysis. Each flask contained 2·65 ml. of the cell suspension in the main chamber; 0·15 ml. of 0·3 *M* glucose and 0·2 ml. of a solution containing 20 μc. 5·25 μmoles of D–L leucine per ml., in the side-arm. Gas phase was N_2—CO_2 (95 : 5). 100 = 585 μl. CO_2. ◒, Oxygen uptake. Each flask contained 2·80 ml. of the cell suspension in the main chamber; 0·2 ml. of the above amino-acid solution in the side-arm; 0·2 ml. of 20 per cent potassium hydroxide in the centre well. Gas phase as air. 100 = 205 μl. O_2. The contents of the side-arm were tipped after a 10-min. equilibration

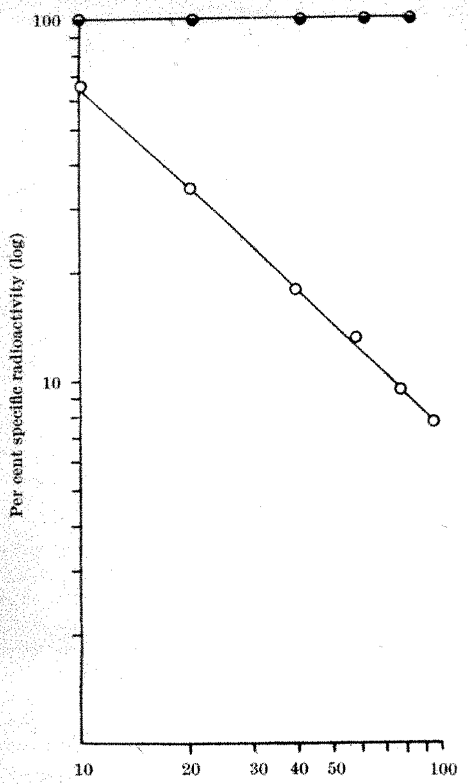

Fig. 2. Effect of increasing doses on incorporation of 1-^{14}C-leucine into protein of the hepatoma cells. ○, Anaerobic incorporation 100 = 380 c.p.m./mgm. protein; ●, aerobic incorporation 100 = 655 c.p.m./mgm. protein

1·4 m.mole; potassium dihydrogen phosphate 1·4 m.mole; sodium-phosphate buffer, *p*H 7·4, 10·6 m.mole.

The cell suspension was placed into a cylindrical 'Perspex' container and irradiated at room temperature with filtered X-rays delivered by a therapeutic beryllium-window X-ray tube operated at 80 kVp. and 5 m.amp., using a 0·1-mm. aluminium filter so that the half-value layer was 0·11 mm. aluminium (equivalent 2·2 mm. water) and the dose-rate at the target distance used (7·5 cm.), 6,800 r./min., measured in air. The depth of the irradiated cell suspension was made up to 3 half-value layer with respect to water. Care was taken to resuspend cells by frequent stirring during irradiation.

About 30 min. after irradiation, cell suspensions were incubated in conventional Warburg apparatus at 38° C. and anærobic glycolysis or uptake of oxygen determined by the conventional methods[4]. After addition of glucose and amino-acid, manometric readings were taken for 60 min. The reaction was then stopped by adding ice-cold trichloroacetic acid (final concentration 1 per cent). Proteins, purified according to Rabinowitz, Olsen and Greenberg[5], were homogenized with absolute ethanol, plated in stainless-steel planchettes and counted with a thin mica-window Geiger–Müller counter.

The results, presented in Fig. 1, show that following irradiation with increasing doses of X-rays respiration is practically unaffected whereas anærobic glycolysis appears progressively impaired. The decrease of glycolysis is directly proportional to the logarithm of the dose of X-rays administered.

Results presented in Fig. 2 clearly show that the aerobic incorporation of 1-^{14}C-leucine into protein, in the absence of glucose, is essentially unaffected even at the highest doses while the anaerobic incorporation of the amino-acid is progressively impaired. When specific radioactivity of protein and X-ray doses are plotted logarithmically, a linear relationship is obtained. The regression equation relating specific radioactivity of protein to *in vitro* X-ray dose is therefore of the form:

$$\log I_D = \log I_0 - K \log D$$

which can be rewritten in the terms of a power law relationship:

$$I_D = I_0 D^{-K}$$

where I_0 represents the value of specific radioactivity of protein at the lowest inhibition dose, taken as zero point at the origin of the co-ordinates, and I_D the value of specific radioactivity of protein corresponding to any dose D. Values of K, that is, the slope of the incorporation curve, were calculated from the dose which halves incorporation ($D_{\frac{1}{2}}$):

$$K = \frac{\log 2}{\log D_{\frac{1}{2}}}$$

The values of K, so calculated, were practically the same in all experiments performed (0·94 in my experimental conditions).

The results presented indicate that when glycolysis is linearly inhibited, incorporation of amino-acids into protein is exponentially inhibited.

The finding that incorporation of leucine is unchanged in ærobic conditions, in the absence of glucose, strongly suggests that enzyme systems involved in protein synthesis are not damaged in the irradiated cells.

The behaviour of aerobic glycolysis and incorporation in the presence of glucose are now under investigation.

Radiation-induced Hyperpyrexia in Rabbits

The response of rabbits to 25,000–50,000 r. radiation exposure is death within 3–4 hr.[1]. Even at lower levels of radiation exposure to 600–1,000 r. a shock-like death occurs in a few animals within 24–48 hr.[2]. However, other biological responses which occur more consistently at these lower radiation dose-levels are depression of the white cell count and reduction in bone marrow activity[3]. This investigation presents evidence that a rise of body temperature is also a regular effect of acute radiation exposure in rabbits.

Virgin female Dutch rabbits weighing 1·2–2·0 kgm. were used for measurement of influence of radiation exposure on rectal temperature. These animals were housed in an animal room with temperature maintained at 70°–72° F., and they were fed a commercially available balanced rabbit diet ('Ambler Simplex

Table 1. THE EFFECT OF X-RADIATION ON RECTAL TEMPERATURE OF RABBITS DURING 4-HR. POST EXPOSURE

Temperature	No. of animals	Average* rectal temperature change (° F.)
Controls (sham radiated)	19	−0·18 ± 0·11
100 r. exposure of head	6	0·12 ± 0·20
200 r. exposure of head	6	1·08 ± 0·20
800 r. exposure of head	6	2·05 ± 0·20
800 r. exposure of head preceded by 200 mgm./kgm. of aminopyrine orally	6	0·13 ± 0·20

* Average change represents the mean difference between the average of 4-hourly post-radiation rectal temperatures and pre-radiation control temperatures and the associated standard errors.

Rabbit Pellets' prepared by the Ambler Milling Co., San Gabriel, California).

Clinical type rectal thermometers were used according to the manufacturer's specifications for accurate observation. (Apex No. 313 rectal thermometers manufactured by the Faichney Instrument Corp., Watertown, New York, were used.) Rectal temperature measurements were carried out according to methods found acceptable in regular laboratory practice[4,5].

The rectal temperatures of rabbits were determined before radiation exposure and at 4-hourly intervals thereafter in a temperature-controlled animal room. Between measurements the animals were maintained in cages without food or water. For measurement of control temperature response a group of animals received a sham radiation exposure as part of the treatment. Temperature response was determined as the change between the pre-radiation control temperature-level and the average of the four post-radiation readings.

For X-radiation of each rabbit, the subject was placed in an animal box through one end of which the animal's head was held in position. For radiation of the head alone, a piece of lead plate 1-cm. thick was placed on top of the animal box to protect the body from the direct radiation beam. A Picker 250 kVp. industrial X-ray unit, operated at 15 m.amp., provided a radiation beam having a half value layer of 1·93 mm. copper at a rate of 80 r./min.

A summary of experimental measurements is given in Table 1, while representation of fever curves are presented in Fig. 1. By variance analysis techniques[6], the results can be shown to substantiate the occurrence of a hyperpyretic response following a sufficient amount of radiation of the head alone. The consistent febrile response following radiation of the head is shown to have an apparent threshold between 100–200 r. and that oral administration of aminopyrine at an optimally effective dose[7] of 200 mgm./kgm. clocks the appearance of the fever.

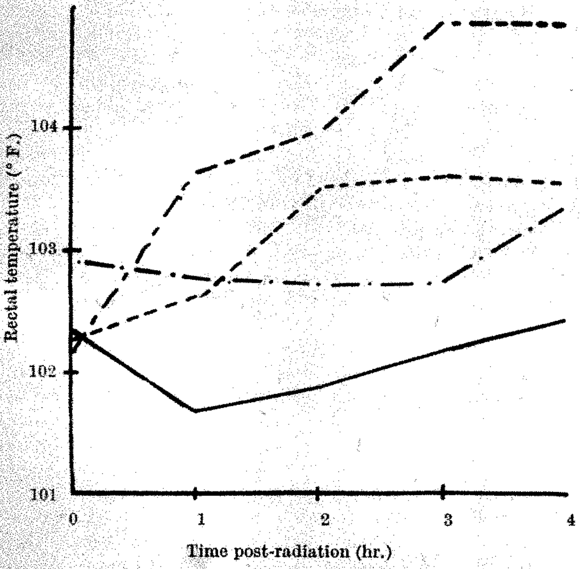

Fig. 1. Change in rectal temperature following acute radiation of the head. ——, Control; —·—, 100 r.; - - -, 200 r.; — — —, 800 r.

The results strongly indicate the susceptibility of the cephalic region of the rabbit toward radiation-induced hyperpyrexia. The significance of this finding is enhanced by the work of Ransom[8], who demonstrated that the site of temperature regulation is situated in the hypothalamus. In the instance of the rabbit, also, it has been well shown that an intact sympathetic nervous system is essential for a febrile response[9]. That the response mechanism is not incited in the effector sequence controlled by the hypothalamus is shown by the capacity of aminopyrine to block the response. This antipyretic has been established to act directly on the thermoregulatory centres[10].

Thus, the radiation-induced febrile response would seem to be evoked through the hypothalamus following an exposure as low as 200 r., but that direct radiation of the hypothalamus is not necessarily the immediate cause of the hyperpyrexic response.

BIOLOGY

Effects of Pre-Inoculation Host Temperature on Infection of Cereal Seedlings by *Puccinia striiformis*

THERE have been several reports concerning effects of post-inoculation temperature on reaction type of wheat varieties to certain races of stripe rust (*Puccinia striiformis* West)[1,2]. On the other hand, there is very little information available on the effects of pre-inoculation host temperature. Apparently the temperature during this phase of plant growth has been held constant or has been stated to be that obtained with ordinary greenhouse conditions.

In the investigation reported here on the effects of environment on the infection process of *P. striiformis* the pre-conditioning phase was studied first as one of the initial phases in the process.

Uredospores of *P. striiformis* used in this investigation were originally collected from a field near Bozeman, Montana. Tests on the standard differential host varieties received from Dr. H. Brewer, Frankheim, Germany, indicated only one physiological race in the collection. The physiological race used in this work apparently has not been previously described either in North America or Europe[1,3–5]. Immediately following collection the uredospores were lyophilized[6] in 40-mgm. quantities, and these spores were used in all future tests. Germination generally ranged between 40 and 60 per cent when spores were hydrated[6] prior to inoculation.

Several wheat and barley varieties were grown in controlled environment chambers either at 15° or 24° ± 1° C. two weeks prior to inoculation. The photoperiod was 12 hr. a day at 2,000 ft.-candles and relative humidity was maintained near 70 per cent. Previous tests showed that the difference in saturation deficit at the two temperatures was not critical. The primary leaves of the seedlings were inoculated in a settling tower using a carbon dioxide gun[7]. About 800 spores were deposited per cm.^{2} of leaf area and distribution was fairly uniform. Following inoculation the plants were returned to a controlled environment chamber where dew was simulated in the dark at 7° ± 0·5° C. After a 24-hr. dew period, the plants were returned to a temperature of 15° C. for post-dew incubation of about 14 days. Light and humidity conditions were the same as previously stated. The plants were then rated for reaction type and relative severity of infection (Table 1).

* Two tests for each variety, a total of at least 25 plants examined per variety.

† 0, Chlorosis or necrosis, no pustules; 1, chlorosis, necrosis, isolated very small pustules; 2, chlorosis, few small pustules; 3, chlorosis, normal pustules; 4, no chlorosis, normal pustules.

‡ Percentage of leaf area covered by rust infection.

The varieties could be separated into 4 groups on the basis of reaction type after host preconditioning. Some varieties such as Westmont and Lemhi were susceptible with both treatments, Rio was resistant with both treatments, Omar, Triplet and Idaed were resistant when preconditioned at 24° C. and susceptible when preconditioned at 15° C., Manchuria was susceptible when preconditioned at 24° C. but resistant when preconditioned at 15° C. A number of other wheat varieties were investigated, and those which were temperature-sensitive usually showed a change from susceptibility to resistance with increased temperature prior to inoculation; however, two of the differential host varieties, Holzapfels Früh and Webster, showed a shift towards greater susceptibility when preconditioned at 24° C. as compared with 15° C.

In these tests, the amount of infection or severity has varied with different host–parasite combinations, but has usually been greater when plants were grown at the lower temperature prior to inoculation. With the exception of Westmont, all varieties exhibiting susceptible type reactions when preconditioned at 15° C. showed more infection at these conditions as compared to those preconditioned at 24° C.

The results show that pre-inoculation host temperatures are also important in conditioning reaction type of wheat and barley to *P. striiformis*. Since physiological host changes conditioning reaction type may take place in the absence of the parasite, biochemical studies on the nature of resistance should be less complex. This investigation also points out that pre-inoculation conditions can influence physiological race determination. Finally, the results of this study have been helpful in interpreting field behaviour of some wheat varieties affected with stripe rust.

In future work the time–temperature period for rust reaction change will be further clarified and the effects of environment on the other phases of the infection process will be studied.

Possible Angiosperms from Lower Permian Coal of the Transvaal

THE accompanying photograph (Fig. 1), which is natural size, represents two out of five white concretions found recently embedded in bright bituminous coal in a pillar of the underground workings on No. *C* seam of the Breyten Colliery in the eastern Transvaal, South Africa. They have every appearance of being of organic origin and suggest the mineralization of angiospermous fruits of a type far more advanced than any yet contemplated in sediments of this age, namely, lower Permian. The coal seam is horizontal and is the lowest exploitable one in the Coal Measures (Middle Ecca) of this area. *Glossopteris* leaves are known from overlying sediments. The rank of the coal is evident from the photograph, and an age not less than lower Permian is supported by spore determinations.

Each of the five objects shows constant features—a smooth outer cover, which may have been spongy and thus suggestive of an aquatic environment; an inner, possibly originally fleshy, layer which is broadest at the apex (the mineralization of these two layers differs), and a central body consisting of a number of curved, club-shaped empty compartments which radiate from the base and perhaps from a central column. The walls between these are invariably double and are very fragile. They suggest a mineral lining of each compartment at a time when the organic membrane still separated them.

The sections illustrated are natural fractures and fortunately almost true longitudinal sections.

While searching for a suitable embedding medium which would allow the cutting of transverse sections,

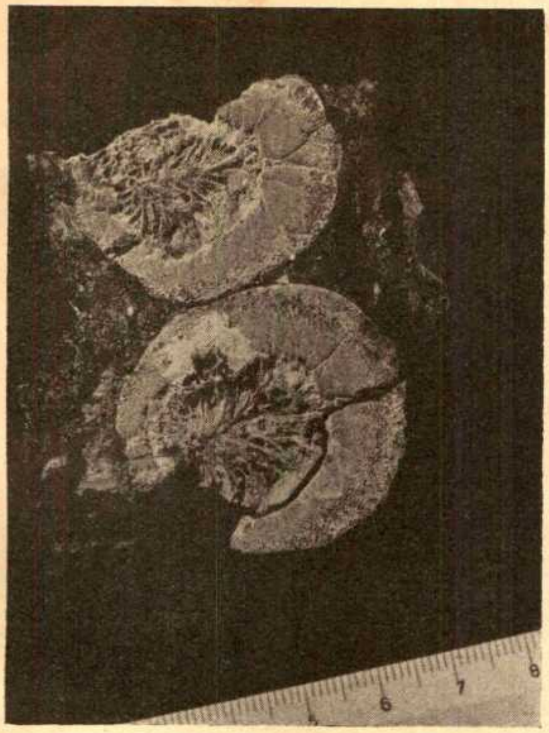

Fig. 1

and not affect the coal, the only thin section has been cut from the fractured outer portion which can be seen on the right-hand side. The whole section was yellowish in colour, remnants of cell structure could be seen and several interesting features such as the presence in one area of what appear to be small fibres and in another of oil glands. These are preliminary announcements but are submitted in support of the probable organic origin of the specimens.

Photographs have been sent to the Royal Botanic Gardens, Kew, for investigation and more details will be published later.

If these are indeed fructifications as they appear to be, their relationship is difficult to imagine. They bear no resemblance to any of the seven 'types' of fructification of Glossopteridae which have been found in South Africa[1], and which are now regarded by a number of plant morphologists as the precursors and possibly the direct ancestors of angiosperms[2,3].

Among much later fossil fruits they are somewhat reminiscent of a silicified multilocular fruit from the Deccan Intertrappean Series of India, which was described by Sahni[4] as *Enigmocarpon* but is now believed to be related to the Lythraceae.

It is possible that the mineralization might have occurred before the specimens were deposited in the swamp. This is suggested not only because no other mineralization has been seen anywhere in the seam but also because coal balls are so far unknown in South African coal deposits. This has been attributed to the complete absence of associated marine sediments from which calcium carbonate might have been derived. After many years of investigation I have found only two apparent coal balls and both proved to be boulders of silicified wood, probably introduced from an older formation.

I have for some time speculated on the higher stage of development and the degree of versatility which are apparent in the Upper Palæozoic fossil plants of the southern hemisphere and have considered the possibility that they might have provided a direct line of descent for angiosperms. The present discovery may provide further evidence.

Respiration-rates of Bacteria, Bean Roots, and Bean Root Mitochondria as a Function of Oxygen Concentration

IT has been found that the frequencies of X-ray-induced chromosomal aberrations in the root-tips of *Vicia faba* at low oxygen tensions is much higher in the presence than in the absence of respiratory inhibitors[1,2]. The inhibitors were effective only in the presence of oxygen, and their effect appeared to consist essentially of causing the oxygen effect[3] to appear at much lower oxygen concentrations than it does in untreated roots. It was suggested that the chemicals in question enhance the X-ray sensitivity by eliminating an oxygen gradient, which is thought to exist in the roots at low oxygen tensions[2].

A possible way of demonstrating the existence of such an oxygen gradient in bean roots would be to determine the relation between oxygen consumption and oxygen concentration for excised root tips and for mitochondria isolated from the roots. The decrease of the oxygen consumption of plant roots, which is obtained when the oxygen concentration is lowered below that in air, is commonly believed to be due to the fact that the diffusion of oxygen into the roots is prevented by the oxygen consumption of the outer cell layers[4–6]. As a result, fewer and fewer of the root-tip cells are taking part in the oxygen consumption as the oxygen concentration in the surrounding solution decreases. In agreement with this explanation, no decrease of the oxygen consumption with oxygen concentration is observed in the case of unicellular organisms, such as bacteria and yeast, at oxygen concentrations higher than 0·3 per cent[7,8].

If the oxygen gradient hypothesis is correct, it would be expected that mitochondria isolated from roots should behave as unicellular organisms so far as the relation between rate of respiration and oxygen concentration is concerned. That this actually is the case is shown in Fig. 1, where the relation between oxygen consumption and oxygen concentration is illustrated for a bacterium (*Escherichia coli B*, methionine-less), for root tips of the broad bean, *Vicia faba*, and for mitochondria isolated from bean roots. It is evident from the figure that for the oxygen concentrations studied, that is, 0·1–1·8 per cent in the gas phase or 1·3–25·0 μM in solution, the oxygen uptake by *E. coli* and by bean root mitochondria is little affected by the oxygen concentration, whereas that of the root tips decreases strongly with the oxygen concentration. The small decrease of oxygen uptake in the case of mitochondria may be due to diffusion of co-factors from the mitochondria. No

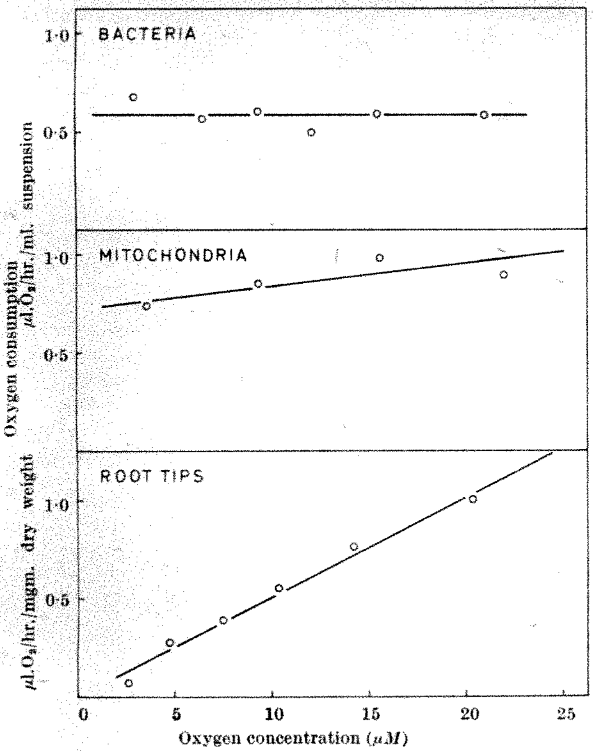

Fig. 1

such decrease in activity was found in a Warburg experiment, which was run parallel with the Hersch cell experiment in order to check the mitochondrial activity during the experimental period. The discrepancy may be explained by the fact that in the Hersch cell experiment the mitochondrial suspension was 80 times more diluted than in the Warburg experiment. This resulted in a much steeper diffusion gradient in the former.

Oxygen consumptions were determined by a method originally developed by Dewey and Gray[9]. Uptake of oxygen took place at 20° C. in a 10-ml. syringe. The syringe was completely filled (no gas phase) with the reaction medium, in which the experimental material was suspended. The composition of the medium was: (1) for *E. coli*: KH_2PO_4, 0·022 *M*; $MgSO_4$, 0·008 *M*; NaCl, 0·085 *M*; NH_4Cl, 0·187 *M*; Na_2HPO_4, 0·042 *M*; glucose, 0·022 *M*; (2) for mitochondria: phosphate buffer, 0·02 *M*, *p*H 7·1; sodium succinate, 0·03 *M*; sucrose, 0·4 *M*; $MgSO_4$, 0·001 *M*; EDTA, 0·1 m*M*: (3) for bean roots: phosphate buffer, 0·017 *M*, *p*H 7·1; glucose, 0·5 per cent.

At the beginning of the experiments the oxygen concentration of the media was adjusted to approximately 27 μ*M*. At 7–15 min. intervals a 0·8-ml. sample of the medium was introduced into a Hersch cell[10] for determination of the oxygen concentration. The oxygen uptake was calculated from the difference between the successive measurements.

In the root experiment, 25 lateral root tips, 3 mm. long, were used.

Mitochondria from roots grown under sterile conditions were prepared essentially according to the method described by Millerd[11] but with the use of ethylenediamine tetraacetic acid[12].

The number of bacteria in the mitochondrial preparation was determined by plating after the end of the experiments. It was found to be approximately 2 × 10^5 per ml. of reaction medium, which is 40 times less than the number which would give the measured oxygen uptake under the experimental conditions.

In the experiment with *Escherichia coli*, a methionine-requiring mutant was used in order to prevent multiplication during the experimental period.

Culture and Sex Modification of Male Cucumber Buds *in vitro*

Sex expression in plants has been the subject of many investigations, which have been thoroughly reviewed by Heslop-Harrison[1]. In recent years attention has been mainly directed to the use of growth substances in the experimental modification of sex expression. Much of this work was done with cucumber (*Cucumis sativus* L.). Laibach and Kribben[2] found that application of auxins such as indolyl-3-acetic acid (IAA) and 1-naphthalene acetic acid may cause earlier occurrence of pistillate (female) flowers in cucumber plants. Application of gibberellins was found to affect their sex expression in the opposite direction[3].

In the earlier work the growth substances were applied to the intact plant. The present work was planned with a more direct approach. An attempt was made to culture very young floral buds, at a stage when they are morphologically and physiologically still bisexual[4], and to apply the growth substances directly to the floral buds. By following their morphogenetic changes induced by IAA, gibberellic acid (GA_3), or a combination of the two, it could be learned whether these growth substances exert their effect only when given to the plant, that is, in some indirect manner, or whether they can act directly on the buds, without the obligatory interference of leaves and other plant organs. Results given here tend to confirm the last possibility, at least in respect to IAA.

Plants of a pure, monœcious line of cucumber were grown in the Earhart and Campbell Plant Research Laboratories at constant conditions (23° day and 19° night temperature and 18 hr. light). Under such conditions the first 20 nodes of the main shoot bear only staminate (male) flowers. Twenty days after planting the seedlings were gathered, dissected and floral buds of the same developmental stage (about 0·7 mm. in diameter) were used for culturing. They were at the bisexual stage and borne on about the eighth node.

To eliminate contamination of the buds, the upper parts of the seedlings were immersed for 4 min. in 1 per cent sodium hypochloride, dipped in ethanol and washed in sterile water before dissection took place. The culture medium was White's basal medium as given by Henderson *et al.*[5] with the addition of 5 mgm. tryptophan, 0·1 mgm. kinetin, 2 ml. casein hydrolysate and 150 ml. coconut milk per litre. Agar concentration was 0·8 per cent and sucrose concentration 2 per cent. Only the agar and sugar part of the medium was sterilized by autoclaving. The rest of the medium, as well as the IAA and GA_3 solutions, were filter-sterilized separately and mixed before pouring the medium into the culture vials. Two buds were planted in one vial and kept at 25°–26° C., 12 hr. light (white fluorescent tubes, intensity about 160 foot-candles) for twenty days. Fig. 1 (left side) showed the vial type and the change in size of bud during culture. The buds reached a size of up to 9 mm. in length during this culture period; attached buds of this size are sexually fully differentiated, containing either a well-developed ovary and abortive staminal rudiments, or well-developed stamens and only traces of an ovary (a depression in the top part of the receptacle)[4]. At the termination of culturing, the buds were fixed, and permanent histological slides were used for the evaluation of the results.

Results are summarized in Table 1. It seems to be clear that ovaries develop only when the buds are grown in media supplemented with IAA. The most effective concentration was 0·1 mgm./l. in which 12 out of 13 cultured buds showed a fairly well-developed ovary. In addition to the concentrations shown in Table 1, lower concentrations of IAA (0·01 and 0·03 mgm./l.) were also tested but caused ovary formation in only 3 out of 6 and 2 out of 5 buds, respectively.

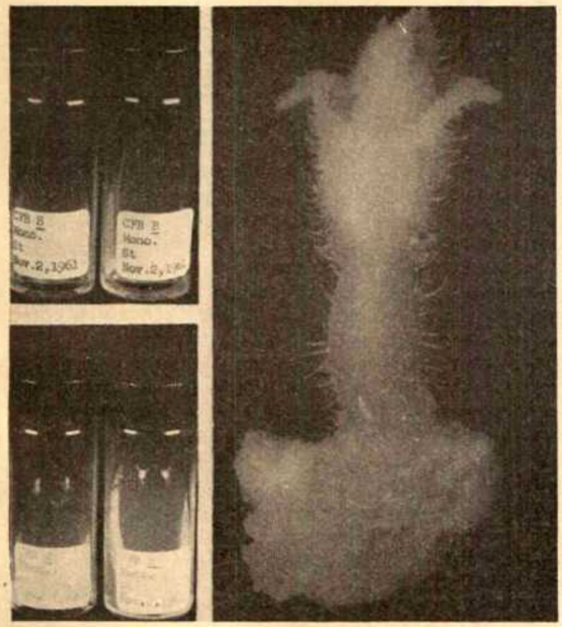

Fig. 1. Left, culture-vials, each containing two floral buds; buds planted on medium without IAA or GA_3, at the beginning (top) and termination (bottom) of culturing period (× 9/20). Right, female floral bud which developed after 20 days culture in an IAA-supplemented medium, from a potentially male bud. (× 6)

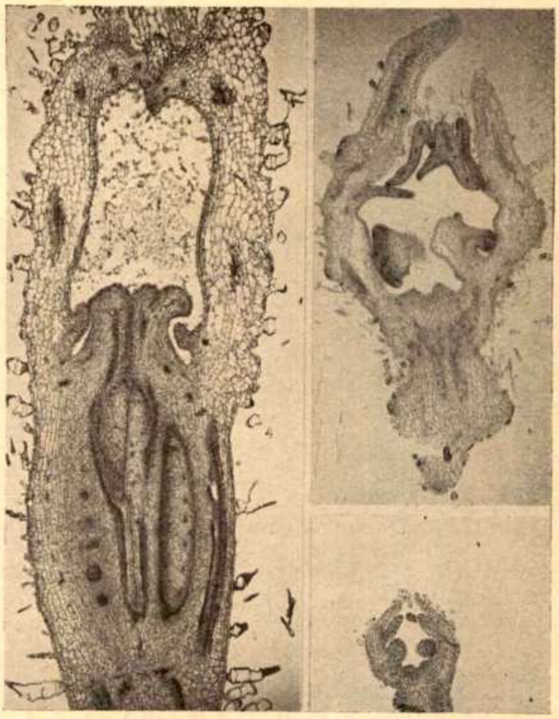

Fig. 2. Longitudinal sections of cucumber floral buds, all at the same magnification (× *c.* 21). Lower right, at the beginning of culturing. Upper right, after 20 days of culturing on medium without IAA and GA_3. Left, after same period on IAA-supplemented medium. Note the lack of appreciable change in the anther primordia in the female bud

In Fig. 2, sections of floral buds at the beginning of culture, and after 20 days of culture in either 'standard' (no addition of either IAA or GA_3) or IAA-supplemented medium, are presented. A bud grown for 20 days in an IAA medium is shown on the right side of Fig. 1. The bud was 9 mm. long and the well-developed ovary can be recognized even without dissection. The stamens in buds of this type were arrested at an early stage of development, as in female buds developing on the plant.

It should be kept in mind that all floral buds used in this work, if left *in situ*, would have become male flowers—according to the node from which they were removed. It is therefore of interest that they can be induced to develop into female flowers when grown detached from the rest of the plant. It is further remarkable that such a development occurs only in the presence of IAA. This acid thus seems to be able to affect sex when applied directly to the floral bud. As to the effect of GA_3 it can at present only be noted that it seems to reduce the effect of IAA when applied simultaneously. The stamens of buds grown in

Table 1. OVARY FORMATION IN POTENTIALLY MALE CUCUMBER FLORAL BUDS CULTURED IN DIFFERENT CONCENTRATIONS OF IAA and GA_3

* Slight development of ovary.

the presence of GA_3 were further developed than stamens in the female buds formed on IAA media.

The present is the only report, to our knowledge, of a successful culture of young floral buds and a direct, differential effect on their male and female parts. Work is now in progress with potentially female and hermaphrodite floral buds, as well as with buds of still earlier developmental stages, which can exhibit a somewhat different behaviour (a greater tendency to ovary formation).

This work was in part supported by research grants *G*–16408 and *G*–17483 from the National Science Foundation.

Clonal Propagation as a Practical Means of Exploiting Hybrid Vigour in Rice

MARKED vigour has been observed in rice by a number of workers in the F_1 generation of many crosses in respect of height, number of ear-bearing tillers, number of spikelets and yield. But it has not been possible to exploit this phenomenon, as hybrid seed production is a limiting factor in this crop. One method of taking advantage of the hybrid vigour might be to multiply the F_1 plants vegetatively. The technique of vegetative propagation in rice varieties which possess perennating habit has been studied intensively at the Central Rice Research Institute from 1959 onwards. Its value has now been established as an aid to increased rice production. The great potentiality of this technique is shown by the fact that all the clones to be planted in an acre have been derived by repeated multiplication of the tillers produced from two to three stubbles (clones) of the preceding crop. The number of repeated multiplication (3–6 times) depends on the nature of rice variety utilized. The increased yield, obtained by this procedure, ranged from 17 to 61 per cent, as compared with crops raised from normal rice seedlings.

Experiments were continued during 1961 involving a number of improved varieties together with their hybrids in F_1 and F_2 generations in order to obtain more information on the usefulness of this practice.

In six cross-combinations, it has been found that a sufficiently good crop could be obtained from F_1 plants, multiplied vegetatively (Table 1).

To test the effectiveness of this technique at the F_2 generation, stubbles of eleven F_2 plants were propagated vegetatively from a cross between *J*.192 (a selection from a fine-grained variety of Orissa) and *GEB*.24 (a popular variety of Madras). The fourth tiller-separation stage was the final planting of the clones as a field crop in the main season and the results are presented in Table 2.

Table 1. F_1 PLANTS OF DIFFERENT CROSS-COMBINATIONS OF RICE VARIETIES, MULTIPLIED VEGETATIVELY AND FINALLY PLANTED DURING THE MAIN SEASON OF 1961

Cross-combination F_1	Total No. of plants at final planting (12 in. × 6 in.)	Area occupied (acres)
W.114 × *GEB*.24	36,657	0·42
GEB.24 × *G.S*.137	25,520	0·29
PTB.10 × *W*.112	2,532	0·03
CH.45 × *W*.135	17,888	0·20
W.140 × *T*.412	61,080	0·70
JBS.120 × *T*.141	17,482	0·20

Table 2. VEGETATIVE MULTIPLICATION OF F_2 PLANTS AND PARENTS FROM A CROSS, *J*.192 × *GEB*.24, CARRIED OUT DURING 1961

Material	No. of tillers first planting	No. of tillers second planting	No. of tillers third planting	No. of tillers fourth planting (final planting 12 in. × 9 in.)	Area occupied (acre)
J.192 (parent)	15	76	430	6,703	0·12
GEB.24 (parent)	27	81	325	3,433	0·06
F_2 plants					
1	18	123	940	10,020	0·17
2	14	87	675	9,440	0·16
3	15	202	1,832	22,832	0·39
4	17	157	1,425	13,480	0·23
5	20	113	800	8,738	0·15
6	15	142	1,366	13,250	0·23
7	15	167	1,318	13,140	0·23
8	13	48	369	5,026	0·09
9	23	109	1,050	9,848	0·17
10	16	88	950	7,655	0·13
11	24	148	1,350	7,740	0·13

Considerable variability was observed in the individual F_2 populations in respect of multiplication of plants (tillering potential) and all the F_2 plants had shown higher production capacity except one (No. 8), as compared with the parents. These observations indicate the possibility of exploitation of hybrid vigour at the F_2 stage as well, with an added advantage that F_2 plants with desirable recombinations can be picked up.

Intercellular Cohesion and Expansion Growth in Higher Plants

FREQUENTLY the growth of plant organs such as the root or coleoptile is considered in terms of the changing number, or size, of the component cells, and the effect of experimental treatments (or environmental changes) on the overall growth is considered in relation to the primary metabolism of the average component cell. Such an approach must fall short of describing in full the growth of the organ if it assumes that tissue behaviour is no more than the summation of the behaviour of individual isolated cells. In a healthy tissue the constituent cells are always firmly attached to each other, and this attachment and any change in it are likely to be of great importance to the growth of the tissue.

Cohesion between parenchymatous cells can be considered in terms of the linking of primary walls, across the region occupied by the middle lamella. Two versions of this system are illustrated in the models 1 and 2 of Fig. 1, where the primary walls of adjacent cells are indicated by the lines *AA* and *BB*, and the intervening space represents the middle lamella, which is traversed by linkages. In model 1 the arrangement of the links is regular, at right angles to the two walls, and in model 2, the arrangement of the links is random. When the two walls expand the increase in area of the two surfaces is the same and would be represented by an increase in *AA* identical with that of *BB*. This increase could be brought about either by uniform expansion of the whole areas, or by an identical gradient of expansion in *AA* and *BB*. In model 1, the consequence of expansion will be to enlarge the spacing between adjacent links, but otherwise produce no disturbance to the linkage system; in model 2, the individual link will be stretched to the elastic limit. Extension growth beyond this point must rupture the link; but the alternative possibility arises that if the summation of the mechanical strength of the individual links exceeds the forces of expansion then extension growth must cease. The extension growth of a cell normally produces a ten-fold increase in length, and frequently a value far greater than this. It is inconceivable that this increase lies within the elastic limit of the materials involved and therefore quite certain that with randomly disposed linkages extension growth must be accompanied by rupture of some linkages in the middle lamella.

In a plant tissue the linkages between the cells cannot be regular as in model 1 without scattering incident energy as a detectably regular pattern, and in parenchyma sliding growth in the sense of a given cell being displaced in the direction of growth relative to adjacent cells does not occur; the extension growth of adjacent cells is simultaneous and to the same extent[1], and so the conditions of model 2 prevail. The conclusion appears inescapable, therefore, that accompanying growth in this tissue, linkages between adjacent cells must be broken. Since cohesion is nevertheless maintained in the tissue, it is clear that accompanying the breaking of linkages is a complementary process of linkage formation.

The inference that growth must be accompanied by the rupture of lateral linkages does not show that the breakage is necessarily a direct consequence of the mechanical stresses of growth, and it is conceivable that the rupture occurs by an independent metabolic process that is integrated into the overall phenomenon of extension growth. But nevertheless the significance of inter-cellular cohesion in the tissue is that it may act as a resistance to expansion, and therefore regulate growth.

If the linkage between cells is provided by polymeric macromolecules with a degree of cross-linking (they may not be polysaccharide in nature) then the processes of rupture and formation of linkages become one of covalent bond-breaking and formation, and the general nature of the bonds by which cohesion is maintained is a matter of some importance. In a recent series of observations[2,3], cohesion has been studied by measuring the area to which a fragment of tissue can be compressed under standard conditions after a standard treatment with hydrochloric acid. This technique provides data from which two types of bonding can be distinguished in the middle lamella, one acid-labile, and the other acid-resistant. Under the mild conditions used to rupture the acid-labile bonds it is quite certain that these are electro-valent in character; it has been suggested that the acid-resistant bonds may be covalent, but to establish this with equal certainty would be difficult. The distinction is an important one because of the different properties of the two types, for a system of random covalent bonding in the middle lamella would permit only very limited shear displacement of the contiguous cell walls, and the elastic limit of the bonds would most probably be low, giving some rigidity to the intercellular cohesion, whereas although a multiplicity of electro-valent bonds could produce as strong a linking, the intercellular cohesion would have greater fluidity, the bonds permitting some slight relative movements between the cell walls.

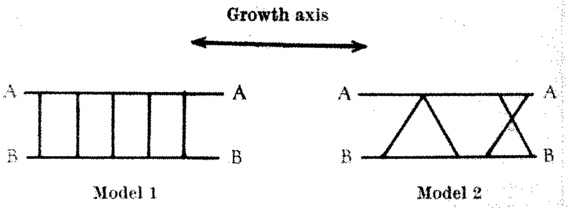

Fig. 1. Alternative models of the linkage system in the middle lamella. *AA* and *BB* represent the primary walls of adjacent cells, separated by the middle lamella which is traversed by linkages. In model 1 these are regularly spaced and perpendicular to the primary walls; in model 2 the arrangement of the linkages is random

The relative contribution of the two bonding systems varies with metabolic conditions. It has been found with root segments that the acid-resistant component is developed most intensively when metabolic activity is depressed, it increases markedly when the tissue is incubated under nitrogen, or with inhibitors such as cyanide, azide, iodoacetate, and *N*-ethyl-maleimide. Evidently the acid-resistant bond is the product of a spontaneous exothermic reaction, which is not linked to an energy-yielding process. The acid-resistant component is poorly developed when the tissue is aerated and freely supplied with sugar, and the data available suggest that the aerobic metabolism of sugar leads to the accumulation of substances in the middle lamella which are active in rupturing acid-resistant bonds.

It does seem significant that the conditions which lead to the formation of acid-resistant bonds are also those which check growth, and that the conditions which weaken the acid-resistant bonding are those which sustain vigorous growth. The restricted growth characteristic of depressed metabolism in anaerobic conditions is not uniquely conditioned by the formation of covalent bonding in the middle lamella. Effects other than those of cohesion are certainly involved in the inhibition and stimulation of growth, but it is possible at least that cohesion is a contributory factor.

Finally, if growth is influenced by the degree of cohesion then changes in the bonding system of the middle lamella might be expected as the tissue develops from a meristematic to a fully expanded state. Such changes have indeed been noted in the root, where the acid-resistant component contributes more to the intercellular cohesion in the meristematic region and in the region of fully expanded cells than it does in the intervening region of cell extension. This suggests that the development from the meristematic to the expanding state involves an enhancement of the metabolic activity through which the acid-resistant bonds are broken, and that subsequent development to the mature state is accompanied by a decay of this system. In terms of the interpretation proposed here, the more vigorous growth that occurs with development from the meristematic state is perhaps partly referable to a decreased restraint imposed by intercellular cohesion, and the cessation of growth may be due in part to this restraint being imposed again.

I thank Prof. R. Brown, in whose Department this work was carried out, for his interest and encouragement.

A. P. Brown

Purification of Chlorophyll *c* from *Sargassum flavicans*

CHLOROPHYLL *c* occurs in many types of marine algae[1]. Little is known of its chemistry or function, and methods used for its quantitative estimation are indirect[2]. The present work describes a method for the crystallization of chlorophyll *c* from the marine alga, *Sargassum flavicans*.

Fresh *Sargassum* weed was macerated several times with acetone/methanol (50 : 50, v/v). The pigment extract was filtered, and the pigments were transferred to ethyl ether by adding an equal volume of ether and washing with 5 volumes of 10 per cent sodium chloride. The ether extract was concentrated to a small volume by evaporation under a stream of air. Chlorophyll *c* was separated from chlorophyll *a* and carotenoids by chromatographing the ethyl ether extract on cellulose powder columns using 0·5 per cent (v/v) *n*-propanol in light petroleum (60°–80°) as developing solvent[3]. Chlorophyll *c* remained as a light green zone at the top of the column. The zones of cellulose containing adsorbed chlorophyll *c* were collected and repacked into a fresh column, and the chlorophyll *c* was eluted with 5 per cent (v/v) methanol in ethyl ether.

The extinction coefficient of this material (chlorophyll *c*, stage 1) at 630 mμ in acetone was 2·24 l./gm. cm. Although free from other pigments, the chlorophyll *c* was heavily contaminated with phospholipid. This was shown by chromatographing an aliquot on paper impregnated with silicic acid according to the method of Marinetti and Stotz[4]. Six lipid fractions were present, and total phosphorus determinations gave values of 1·18 mgm. phosphorus/100 mgm. chlorophyll *c*.

Chlorophyll *c* (stage 1) was partially freed from lipid by chromatography on columns of silicic acid which had been mixed with 'Hyflo Supercel' (2·5 : 1, w/w) in chloroform. Chlorophyll *c* was eluted with 5 per cent methanol in chloroform (stage 2). The extinction coefficient of this material in acetone at 630 mμ was 9·91 l./gm. cm. Four lipid fractions were removed, and total phosphorus determinations gave values of 0·1 mgm. phosphorus/100 mgm. chlorophyll *c*.

The final purification of chlorophyll *c* was achieved by chromatography on columns of neutral aluminium oxide. Chlorophyll *c* was strongly adsorbed at the top of the column. Traces of carotenoid and one lipid fraction were removed with methanol/chloroform (9 : 1, v/v). The remaining lipid fraction was removed with ethanol/chloroform/water, 5 : 2 : 1 (v/v/v). Chlorophyll *c* was finally eluted with ethanol/chloroform/water, 5 : 2 : 2·5 (v/v/v). The emerald-green solution (stage 3) was concentrated by evaporation under nitrogen, until the solution changed colour and a deep copper-red precipitate appeared.

Crystallization was achieved by redissolving the precipitate in the minimum quantity of ethanol, adding water to about 5–10 per cent, and leaving in the dark at room temperature. After 24 hr., reddish-black crystals had separated from the mother liquor. Large crystals (100μ) assumed the habit of parallel-sided plates (Fig. 1) and minute crystals (3–5μ) appeared as hexagonal platelets.

The extinction coefficient of chlorophyll *c* (stage 3) in 100 per cent acetone at 630 mμ was 15·8 l./gm. cm., and the absorption maxima in acetone were at 628, 580, and 442 mμ. Magnesium estimations (atomic absorption spectroscopy) gave a mean value of 2·38 mgm. magnesium/100 mgm. chlorophyll *c* (range 2·13–2·60). Assuming one magnesium atom per molecule, and using the mean value of 2·38 per cent magnesium, the molecular weight of chlorophyll *c* would be 1,020. This is the same order of magnitude as chlorophyll *a* (893) and chlorophyll *b* (907). Granick[5] suggested that chlorophyll *c* was a phytol-free chlorophyll (mol. wt. about 600) on the basis of its low hydrochloric acid number. If phytol is indeed absent, then chlorophyll *c* must possess alternative groups attached to the chlorophyll nucleus.

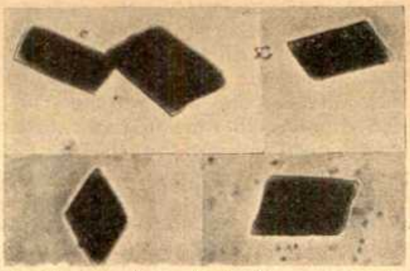

Fig. 1. Chlorophyll *c* crystallized from aqueous ethanol

Detailed descriptions of the methods used and the properties of the crystalline chlorophyll *c* will be published elsewhere.

I thank Dr. B. G. Davey, Faculty of Agriculture, University of Sydney, for the magnesium determinations.

Spontaneous Electrical Activity of Cutaneous Receptors in Mormyrids

Lissmann and Machin[1-3] have demonstrated that the electric fish, *Gymnarchus niloticus*, is several thousand times more sensitive to a moving electrostatic charge or a moving magnet than are other fish. The electric receptors were assumed to be the 'mormyromasts' (special cutaneous organs known to exist in Mormyrids and first described by Stendell[4]); no experimental proof, however, has been presented to show that the electric stimuli indeed act on these organs.

In 1959, while examining the electrical behaviour of very young Mormyrids (*Mormyrops nigricans*), the very feeble discharge of which necessitates the use of strong amplification, I observed that the receiving electrodes dipped into the water and in contact with the fish captured rhythmic electric signals of relatively high frequency (300 impulses/sec.). The spontaneous electric discharge, generated by the electric organs of the fish, did not, in any way, affect the characteristics of these signals (Fig. 1*A*).

In 1961 these experiments were repeated: previous results were confirmed, and it could be definitely proved that on the skin of Mormyrids electric phenomena of different characteristics and location can be found. Briefly described they are as follows:

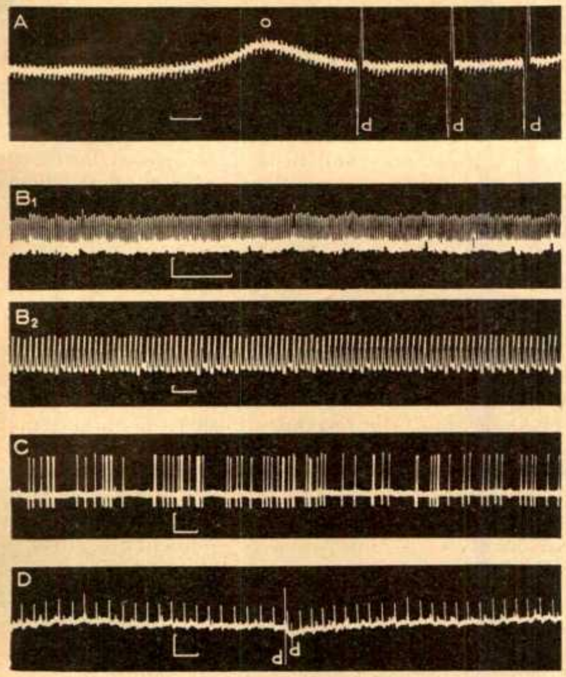

Fig. 1. Different types of spontaneous rhythmic activities recorded on the skin of various Mormyrids. *A*, Young *Mormyrops nigricans*, recording using monopolar electrode placed immediately in front of the operculum. ○, Opercular movement; *d*, discharge of the electric organ. B_1, *C*, *D*, *Hyperopisus bebe*, monopolar recording at three points of the dorsal surface of the head; the fish was kept out of water, respiration being maintained by buccal water-jet. B_2, *Mormyrus hasselquisti*, same experimental conditions as in B_1; recording point 10 mm. dorsolaterally to the eye. Calibration, 1 mV.; time, 20 msec.

(1) Rhythmic discharges of very high frequencies Fig. 1 (B_1 and B_2) up to 2,200 imp./sec. which are limited to certain regions of the head, the dorsal surface of the body and to the base of the dorsal and anal fins. In each of these regions there exist several emitting points. The frequency and amplitude (2–12 mV.) of the impulses are invariable for any given point, but they are different from one point to another. The range of frequencies is around 300 imp./sec. in the case of *Mormyrus hasselquisti* and between 1,100 and 2,200 imp./sec. in the case of *Gnathonemus*, *Hyperopisus*, *Marcusenius* and *Genyomyrus* spp. (Results of preliminary anatomical examination suggest that the particular organization of the bulbar organs of the *Mormyrus* genus may furnish some explanation for the observed differences.)

(2) Spikes of identical amplitude but of irregular frequency the emission of which takes place approximately in the same regions (Fig. 1 *C*).

(3) Exceptional spikes of low (40–140 imp./sec.) and regular frequency (Fig. 1 *D*) the emission of which is situated on the dorsal surface of the head near to the midline.

Similar electric phenomena can be demonstrated on the skin of *Gymnarchus niloticus* after suppression of the functioning of the electric organ either through spinalization of the animal or by blocking electrically the bulbar command of the electric organs[5].

These phenomena are of cutaneous origin. They persist at the level of the dorsal fin of a decapitated fish, but disappear if the skin is crushed locally. A precise localization of the emission points by means of a fine electrode, followed by histological control, showed that the rhythmic discharges of high frequency originate from the "Knollenorgane" (tuberous organs) of Franz[6]. The irregular spikes probably come from some of them; it remains to be determined, however, whether they represent a particular state of functioning of the same organs or the functioning of particular tuberous organs.

These cutaneous discharges are sensitive to electric current and also to changes in temperature[7].

A clue to the role of these organs can be found in my demonstration that the electrical stimulation of the lateral nerve influences the activity of the electric organs: as the tuberous organs form part of the lateral line system[6,8], their activity may be expected to be in close relationship with that of the electric organs.

Thus in addition to their well-known electric organ, the Mormyrids (and *Gymnarchus*) possess in their skin autoactive cells, situated predominantly on the head and at the base of the dorsal and anal fins. They may represent electroreceptors, having an auto-rhythmicity of high frequency the modulation of which would control the activity of the electric organs, via the central nervous system. It is obvious that this permanent activity of high frequency could offer large possibility of modulation, which in fact would explain the extraordinary sensitivity of these fish to electric current, observed by Lissmann and Machin.

A Possible Ultra-Micro Biodetection Method for Androgens

VERY young guppies (*Lebistes reticulatus*) will give a visible morphological reaction to extremely low concentrations of methyl testosterone in the water in an aquarium. Observations indicate that individuals 1–5 days of age are sensitive to concentrations of this steroid in the order of 10^{-12} *M*, and thus to quantities in the μμgm. range, if not lower.

The indicating reaction is the elongation of the anal fin, which is normally a secondary sexual development in maturing males. The hormone-induced change is first detected after 3 days and is very obvious after 5 days.

The stock solution of the steroid was prepared by dissolving crystalline commercially obtained hormone in ethanol and diluting with distilled water, to produce a 10 per cent by volume ethanol solution, $3 \cdot 5 \times 10^{-4}$ *M* in methyl testosterone. A preliminary investigation with methanol as the solvent, however, resulting in more extensive morphological changes in mature female guppies than from later tests with ethanol, suggest that young guppies may be even more sensitive with methanol.

These observations indicate that the phenomenon may be useful for the detection, and possibly also the measurement, of very low concentrations of natural androgens in biological fluids.

Failure of Histamine to induce Deciduomata in the Rat

THE uterus of the pseudo-pregnant rat responds to trauma on the fifth day of pseudo-pregnancy by producing a massive growth of decidual cells. The production of artificial deciduomata was first demonstrated by Loeb in 1908[1] and is analogous to the decidual response of the pregnant uterus to an implanting blastocyst. Why trauma should cause this response, which can result in a four-fold increase in the weight of a uterine horn in 70 hr., is still little understood. Shelesnyak has postulated that the final stimulus to the uterus is histamine, released by trauma or, in pregnancy, by the presence of the egg. The most convincing and probably most crucial evidence is that intra-uterine injections of histamine initiate a decidual response. In these experiments Shelesnyak[2] used a dose of 500 μgm. of histamine dihydrochloride, although in a subsequent experiment he found from bioassay of whole uteri that the total quantity of histamine present in the uterus was approximately 4 μgm. (ref. 3). In addition Kahlson has shown that the urinary output of endogenous histamine is of the order of 100 μgm. a day[4]. In view of these findings 500 μgm. would seem to be a rather large amount of histamine to introduce into one horn of the uterus. Hence it seemed desirable to repeat the experiments with the view of ascertaining whether smaller, more physiological amounts would elicit the response and, if possible, to determine a dose response relationship.

Rats were made pseudo-pregnant by electrical stimulation of the cervix during œstrus. Operation was performed under 'Avertin' anæsthesia 100 hr. later. The uterine horn was approached through a small incision in the flank. A number 30 standard wire gauge needle (0·3 mm. outside diam.) was passed through the wall of the uterus at the utero-tubal junction and into the lumen of the uterus for a distance of ½ in. During the injection the bottom of the oviduct was held between forceps so that the only trauma to the uterus was that due to insertion of the needle. In each animal histamine in 0·05 ml. physiological saline was injected into one horn and 0·05 ml. physiological saline into the other. Solutions were randomly allocated to right and left horns and the operator himself did not at the time of the injection know which syringe contained saline and which histamine. After 72 hr. from the time of the injections, the animals were killed and the uterine horns dissected out and weighed separately. It was hoped that the 'blind' injection technique together with the objective measurement of response by uterine weight would eliminate any unconscious bias. The doses of histamine acid phosphate used were 10, 125, and 500 μgm., with 5 animals per group. For comparison a further group of 10 animals had one horn of the uterus crushed with artery forceps, the other horn being left completely untreated.

As was to be expected, crushing caused a considerable decidual response and consequent increase in weight of the uterine horn (Table 1). The untreated horns in this group contained no deciduomata and provide an estimate of the control weight of the pseudo-pregnant uterine horn. The mean weights of both the saline- and histamine-injected horns, as shown in Table 2, were significantly ($P = 0\cdot05$) greater than the mean weight of the untreated horns. Macroscopically deciduomata were seen in many of the injected horns, especially adjacent to the site of injection. This is not surprising since injections into the lumen of the uterus must always be attended by a certain amount of trauma. However, it is clear that not only is there no increase in response with increasing dose of histamine, but in no group was the response to histamine greater than that to saline. At the same time, the responses both to histamine and to saline were significantly ($P = 0\cdot05$) less than the response to crushing. If this difference were due to the fact that crushing liberates more histamine than does the trauma of intra-uterine injection, one might reasonably expect histamine to augment the effect of saline. But this did not occur.

Table 1

Mean weights and standard errors of uterine horns (mgm.)

After crushing	No interference
341 ± 44·9	141 ± 7·6

Group size = 10

Table 2

Mean weights and standard errors of uterine horns (mgm.)
Group size = 5

Dose (μgm.)	After injection of histamine acid phosphate in saline	After injection of 0·05 ml. 0·9 per cent saline
10	240 ± 42·9	287 ± 72·6
125	167 ± 25·4	211 ± 44·3
500	198 ± 21·7	209 ± 31·3
Overall result:	Histamine injected	201·5 ± 18·6
	Saline injected	235·9 ± 29·5

The structure of the rat uterus is such that passage of fluid from one horn to the other seems unlikely. However, to check this, 5 rats were given saline into one horn and the other left untreated. The results are given in Table 3.

Table 3

Mean weights of uterine horns as before

Injection of saline	Uninjected
244 ± 41·6	155 ± 6·7

The weights of the uninjected horns are not significantly different from those of the uncrushed horns in Table 1 and macroscopically no deciduomata were seen.

After the experiment had been started we noted that histamine dihydrochloride, as used by Shelesnyak, contains a higher percentage of histamine base than does the acid phosphate salt used by us. We therefore injected a further group of 5 rats with 500 μgm. histamine dihydrochloride. The results are shown in Table 4.

Table 4

Mean weights of uterine horns as before

Injection of 500 μgm. histamine dihydrochloride in 0·05 ml. saline	Injection of 0·05 ml. saline
201 ± 21·8	176 ± 12·9

Again, there is no significant difference between the response to histamine and that to saline or between the response to this salt of histamine and the response to the acid phosphate (Table 2). Thus we have been unable to show that intra-uterine injection of histamine in saline causes a significantly greater decidual reaction than intra-uterine injection of saline alone.

MICROBIOLOGY

Spherical Pseudomorphs in Aerosols of *B. lactis aerogenes*

During an investigation of bacterial aerosols formed by spraying from a suspension, a striking effect was observed which does not appear to have been reported previously. A small quantity of washed *B. lactis aerogenes* in distilled water was sprayed from an atomizer and the resulting aerosol passed through an evaporation tube to dry the organisms. Samples for electron microscopy were obtained with a thermal precipitator by direct deposition on to collodion-covered specimen grids. Instead of elongated bodies, spherical particles, the shape of which was verified by shadowing at 45°, were found (Fig. 1, above). The diameter of many of the particles was two or three times that of a sphere of the same volume as a given organism, and all particles were uniformly opaque with no sign of a cell wall. Similar shapes were found when sedimentation samples were taken, so the effect could not have been caused by heating during thermal precipitation.

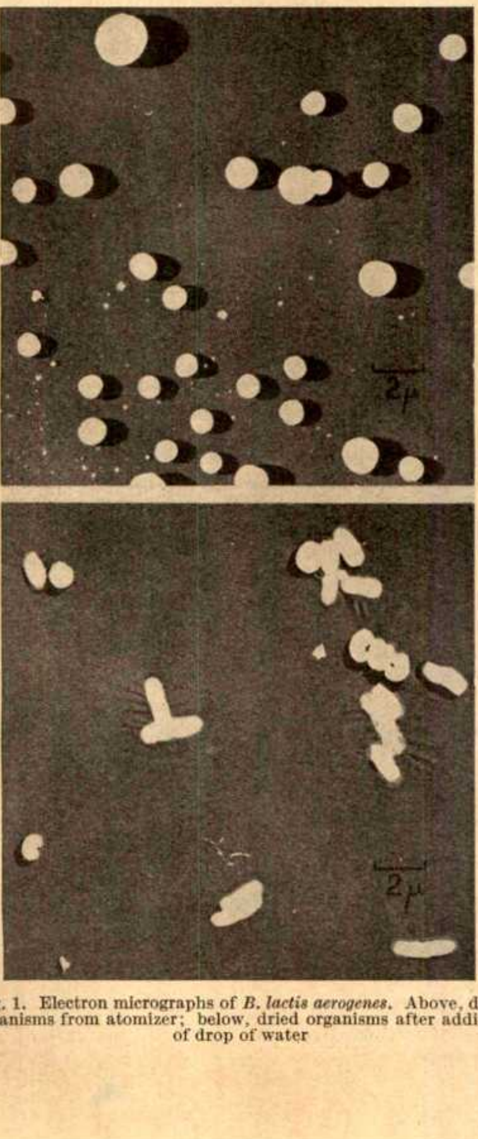

Fig. 1. Electron micrographs of *B. lactis aerogenes*. Above, dried organisms from atomizer; below, dried organisms after addition of drop of water

Attempts were made to regenerate the normal shape of the bacteria by exposure to a high concentration of water vapour; but these proved unsuccessful. However, when a small drop of water was placed on the particles on a grid, which was then allowed to dry before examination, particles in various stages of reversion to their normal shape could be seen (Fig. 1, below). It is apparent that the bacteria folded end-to-end when reaching the spherical shape, an effect which is almost certainly due to the predominant action of surface tension forces in the last stages of evaporation of the spray droplets. The larger spheres shown in Fig. 1 (above) are undoubtedly aggregates of organisms.

In another experiment, organisms were sprayed on to prepared grids so that the droplets impacted before much evaporation took place. Single organisms and closely packed aggregates were found, similar in appearance to bacteria dried on a surface from an aqueous suspension, but no spherical particles were present. It appears that complete evaporation before deposition is necessary for the bacteria to attain the spherical form.

Further experiments, in which spores (*B. globigii*) were sprayed, failed to produce any abnormal shapes.

A Medium for the Axenic Cultivation of *Entamoeba invadens*

Cultures of *Entamoeba invadens* Rodhain, 1934, growing without other micro-organisms, were first obtained in media containing chick embryo or liver tissue[1-4]; these media were prepared under aseptic conditions as they could not be sterilized by heat or filtration. The presence of tissue cells raises some doubts as to whether these cultures should be designated axenic, as defined by Dougherty[5,6], and Diamond[7] attributes the first axenic cultivation of *E. invadens* to Stoll[8,9], whose medium contained particulate matter, but not living cells. Stoll's medium comprised a heat-sterilized liver extract together with sodium chloride, peptone and mucin, to which a Seitz-filtered liver extract was added aseptically. Diamond[7] has developed a medium free of gross particulate matter, but containing inactivated serum, presumably sterilized by filtration, which was added aseptically to a heat-sterilized, buffered solution of Trypticase, yeast extract, maltose and reducing agents. This medium supported the axenic growth of both *E. invadens* and *E. terrapinae* Sanders and Cleveland, 1930.

It was felt that a medium containing only heat-stable ingredients was desirable, as it could be sterilized in one stage, thus simplifying preparatory procedures and reducing the risk of accidental contamination. By progressive modification of Stoll's medium, I have obtained such a medium, which is also free of gross particulate matter. The following substances are dissolved in 100 ml. glass distilled water: 1·0 gm. Trypticase (*BBL*); 2·5 gm. 'Panmede' (a dried ox liver digest manufactured by Paines and Byrne); 0·5 gm. sodium chloride; 0·5 gm. glucose. After adjusting the pH with N sodium hydroxide, the medium is dispensed in 'Pyrex' test-tubes, and autoclaved for 20 min. at 15 lb., 121° C. As soon as possible after removal from the autoclave, preferably while still warm, the surface of the medium in each tube is covered with a layer of sterile 'Vaseline', to prevent aeration of the medium. The tubes are stored at 8° C. until required.

Strain N of *E. invadens*[10] has been growing without other micro-organisms since 1954, and has been maintained in the above medium for more than a year, by sub-inoculation at intervals of 3–4 weeks; the cultures are incubated at 24° C. Although growth in these cultures has been maintained at a consistent level, this, as in other axenic media for *E. invadens*, is very much less than in cultures of the amœbæ growing with bacteria. When 2,500 axenic amœbæ, in 0·5 ml. of 'Panmede'-trypticase medium, are inoculated into 5 ml. of medium (pH 6·0–6·3), optimum growth is attained at 2 weeks, the numbers of amœbæ multiplying approximately ten-fold. A similar number of amœbæ, from a culture of *E. invadens* + *Escherichia coli*, inoculated into a diphasic medium (horse serum slope covered with 5 ml. of Ringer–egg-white + starch) reach optimum growth at 3 weeks, with a 200-fold increase in numbers.

The intensity of growth in this axenic medium appears similar over the pH range 6·0–7·5, with little or no growth below 5·5 or above 8·0. Amœbic growth is not stimulated by the addition of gastric mucin or starch, and in the axenic cultures the avidity of the amœbæ for starch is much less than in mixed cultures of amœbæ and bacteria. In contrast to the readiness with which mass encystation occurs in many mono- and poly-bacterial cultures of *Entamoeba invadens*, sporadic cysts have been found only occasionally in some axenic cultures.

Work on modifications of this medium is in progress, and a more detailed account will be published elsewhere.

A New Species of *Derxia*

A NEW nitrogen-fixing bacterium has been isolated and purified from a sample of partially retted jute plant (*Corchorus olitorius* L.) collected from Gograghat (Uttar Pradesh, India) in nitrogen-deficient mannitol-agar medium. The raised, smooth, capitate, translucent, areolate colonies, formed with a circular or oval depression at the centre having a well-defined margin, are usually hard in consistency when young but gradually become soft and slimy with age. The 5-day-old colonies measure on an average 10·95 mm. × 9·7 mm. The pale yellow colour of the colonies appearing after 3–4 days incubation at 33–34° C. in nitrogen-deficient mannitol-agar gradually changes from light to dark brown. Nitrogen-free liquid medium becomes jelly-like in consistency with change of colour of the pellicules from yellow to chocolate brown. Heavy slimy growth with chocolate brown colour appears in dextrose-nutrient broth. Stab culture in nitrogen-free mannitol-agar always shows surface growth. On streaking in the same medium, colonies are distinct but not separated. In potato slants, slimy rust-brown growth appears after 3–4 weeks at 32–33° C.

The bacterium grows fast, and efficiently utilizes glucose, alcohol, glycerol, mannitol, sucrose, lævulose and sorbitol. Growth is, however, feeble in mannose and maltose, while there is no growth in starch, arabinose, lactose, xylose, galactose, rhamnose, and a number of sodium salts of lower and higher aliphatic acids.

Growth of the bacterium is faster in combined nitrogen than in nitrogen-deficient medium. It effectively utilizes aspartic acid, glutamic acid, asparagine, ammonium acetate, sodium nitrate, peptone, alanine and urea; and shows very feeble and belated growth in ammonium sulphate and in glycine respectively. It reduces nitrate, changes litmus milk alkaline and semi-transparent on incubation. The bacterium does not hydrolyse starch or liquefy gelatine. Indole formation and catalase activity are found to be negative.

The bacterium grows with or without calcium. Molybdenum was found to be essential for fixation of nitrogen. Nitrogen fixation reaches a maximum of 30 mgm. in nitrogen-free liquid medium with 2 per cent glucose on 30 days of incubation at 31°–32° C.

The organism grows at a range of pH 5–9. Growth performance is better in alkaline range which, however, reaches 4·4 during the period of long incubation due to formation of acid.

Three distinct morphological stages are observed in the life-cycle of the aerobic, Gram-negative organism. In nitrogen-deficient mannitol-agar or glucose-agar (inc. at 34°–35° C.) banded cells are found (Fig. 1*A*) with discoid or partially annular chromatic bands in 24-hr.-old culture. This form soon changes to alveolar structure (Fig. 1*B*) within 3–4 days, and finally appeared as rods measuring on average 0·79–4·32 × 0·53–1·16μ with rounded ends (Fig. 1*C*) in old cultures. On staining, the refractive bodies in banded and alveolar cells are found to contain fat and volutin-like inclusions. Cells in young culture are embedded with slimy capsule of variable thickness. Various involution forms generally arise in dextrose-

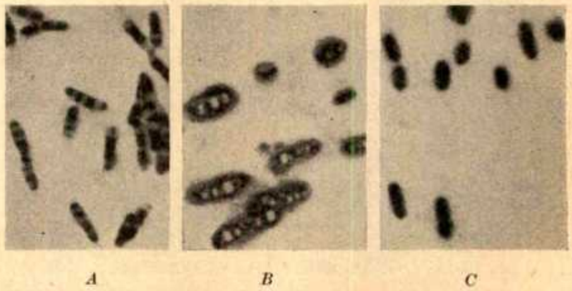

Fig. 1. *A*, Banded cells in 24-hr.-old culture; *B*, alveolar cells in 4-day-old culture; *C*, rod-shaped cells in 12-day-old culture. (× *c*. 1,500; stained in 0·1 per cent crystal violet)

nutrient agar medium. Motility is observed in glucose-ammonium acetate solution after five days of incubation at 34°–35° C. Endospores and microcysts are not formed.

The bacterium differs from *Azotobacter*, *Beijerinckia* and also from the previously reported organisms[1,2] in cultural, physiological and morphological characters. It differs distinctly from *Derxia gummosa* (Jensen *et al*)[3], in its morphological life-cycle, having cells of smaller size, for assimilation of carbon from sucrose and development of feeble growth in ammonium sulphate glucose-agar. In view of its general resemblance culturally and physiologically to the genus *Derxia*, this new organism can be included in the same under a new specific name *Derxia indica* sp. nov.

We thank Dr. K. T. Jacob and Dr. M. K. Mukherjee for their interest and encouragement.

ENTOMOLOGY

Mating of Virgin Queen Honey Bees (*Apis mellifera* L.) following Mandibular Gland Extirpation

Mandibular glands have been suggested as a possible source of an odour that attracts drones to virgin queens for mating[1]. The experiments in this report concern attempts to determine if virgin queens without mandibular glands can mate. Data discussed here are made more significant by the discovery, made after these experiments were conducted, that the mandibular glands are indeed the primary source of mating attractant odours[2].

Nedel[3] first extirpated mandibular glands from a living queen. One of these queens did not mate when given the opportunity, and on this basis he suggested that the mandibular gland was necessary for mating to occur. Gary and Morse[4] and Gary[5] independently developed another technique for mandibular gland extirpation that was used in the following experiments conducted during 1961.

A mature queen cell within hours of emergence was placed in each of five nucleus colonies containing approximately 3,000 bees on June 27. Virgin queen flight was prevented by queen excluder material placed over the colony entrances. On June 30 the mandibular glands were extirpated from the virgin queens. During the gland extirpation, the queens were out of the colonies for 52–77 min. Queen excluders were removed when the queens were returned to their respective colonies. Dead bee traps[6] were attached to colony entrances to collect the bodies of any queens cast from the colonies.

One queen was found dead in the trap 24 hr. after gland removal. Two queens did not mate and were superseded within two weeks. The remaining two queens mated and produced normal worker brood until they were killed two weeks later for a chemical analysis.

In a similar experiment the mandibular glands were removed on July 28 from six virgin queens three days old. In this experiment colonies containing approximately 30,000 bees were used, and dead bee traps were not used. One month after gland removal two of these queens had mated and were laying normally. Incision scars confirmed previous gland removal on both queens.

The extirpation of mandibular glands does not necessarily render a virgin queen incapable of mating. Since some virgin queens without mandibular glands duly mated, it is indicated that drones utilize supplementary stimuli such as vision to locate virgin queens in flight.

This investigation was supported by a research grant (*MY*–3368) from the Mental Health Division, U.S. Public Health Service.

A Diuretic Hormone in *Rhodnius prolixus* Stål

The fifth-stage larva of *Rhodnius* takes very large blood meals[1], and a rapid diuresis follows[2]. The experiments reported here demonstrate that the diuresis is caused by a hormone released into the hæmolymph from the ganglionic mass in the mesothorax.

When the Malpighian tubules, attached to the top part of the rectum, are isolated from a recently fed insect and placed in a drop of hæmolymph under liquid paraffin, they produce urine; and the rate of urine production can be estimated by measuring the size of the drop which appears at the rectum. The rate is at first high, but soon falls to a very low level. If hæmolymph from a freshly fed insect is now added to the hæmolymph bathing the tubules, a further burst of urine production follows. Hæmolymph from an unfed insect has no effect.

Several lines of evidence show that the factor responsible is a hormone liberated from the large fused ganglionic mass situated in the mesothorax (which comprises the meso- and meta-thoracic and all the abdominal ganglia).

The activity of breis of various tissues in insect Ringer was tested by adding them to the tubule preparations. The central nervous system possesses considerable activity; all other tissues tested have no activity. By determining the dilution at which each of the active breis produces a standard effect on the production of urine by tubule preparations, it is possible to measure the activity of each of the parts of the central nervous system. Thus, in arbitrary units per unit of dry weight, the activity of the brain is 6, that of the subœsophageal ganglion 3, the prothoracic ganglion 1, and of the fused ganglionic mass 50.

The fact that ligating the fed insect anterior to the ganglionic mass has no effect on urine production demonstrates that structures anterior to the ganglionic mass are not involved. Thus decapitation is without effect on the normal response. On the other hand, ligating the fed insect behind the ganglionic mass soon causes the flow of urine to cease.

In fed animals which have been ligated at various points, only those portions which include the ganglionic mass contain active hæmolymph (as assayed on isolated tubules).

The ganglionic mass in the mesothorax contains several groups of neurosecretory cells. The diuretic activity, as estimated with tubule preparations, is confined to the cells of the two hindmost groups.

CYTOLOGY

Chromosomes of the Fungus *Cyathus*

Although records of chromosome counts in fungi are fairly numerous, few of these can be considered completely reliable. Indeed the small size of fungus chromosomes and the limitations of techniques of staining make difficult the unequivocal identification of chromosomes as such in many published records.

An extensive list of chromosome numbers can be found in the review of our knowledge of fungus nuclei published by L. S. Olive[1]. Referring to Basidiomycetes (especially members of the Agaricales), Olive notes (p. 548): "reports of odd numbers of chromosomes are rare, as are reports of haploid numbers greater than 8".

Among the Gasteromycetes (to which group the genus *Cyathus* belongs) about a dozen species appear to have been examined, and in these the haploid number given is either 2 or 4 (in one instance a possible 3).

This brief reference is sufficient to indicate a probable basis for the assumption, apparently widespread among botanists, that the haploid chromosome number for common fleshy fungi is 3, 4 or occasionally 6.

That larger chromosome numbers may occur among members of the Agaricales is shown by the work of D. T. Hughes[2] on the wild and cultivated varieties of the common mushroom. The photographs published by Hughes establish the haploid number of 12 for both wild- and cultivated-types.

The accompanying photograph shows that the chromosome number for the fungus *Cyathus stercoreus* (Schw.) De Toni is $n = 12$. So far as we are aware, this is the largest number reported to date for a member of the Gasteromycetes. The demonstration was made possible by the use of a special propiono-carmine staining technique developed by one of us (B. L.). The new technique will be described elsewhere.

From young fruit-bodies of *Cyathus stercoreus* grown on nutrient agar in the laboratory, periodioles were removed and fixed. By careful dissection, young basidia were teased out on to slides and squashed gently.

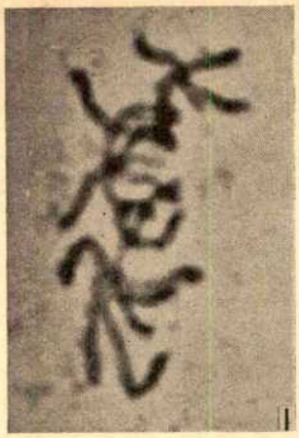

Fig. 1. Photograph of twelve bivalent chromosomes of *Cyathus stercoreus* as seen in a young basidium. (× *c.* 3,200)

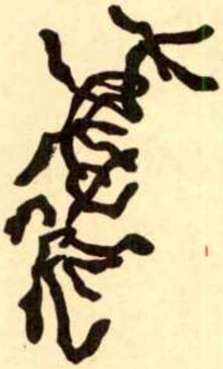

2

Fig. 2. Drawing representing the same chromosomes as seen by focusing through the preparation. (× *c.* 3,200)

The photograph reproduced as Fig. 1 shows 12 bivalent chromosomes at prophase of the first meiotic division in a young basidium. In the actual preparations each chromosome can be seen in its entirety, and considerable difference in size and shape of chromosomes is observable. Fig. 2 is a drawing based on the chromosomes as seen in the several focal planes not shown by the photograph. Other similar preparations confirm the count given. Work in progress indicates that chromosome numbers of other species of *Cyathus* are also of the same order and clearly not less than $n = 8$.

Apparently the chromosomes of *Cyathus* are quite large (at least in the stage shown) in comparison with those of many fungi. It may be that further study will reveal distinctive morphology by which they may be separately identified.

The possibility of determining chromosome number in the various species and races of *Cyathus* will facilitate investigations of genetic mechanisms and of the problems of species relationships in these interesting fungi[3].

This work was carried out with a grant to one of us (H. J. B.) from the National Research Council of Canada.

VIROLOGY

Use of Formalin-treated Antigen in the Production of Antiserum to a Plant Virus

TOMATO black ring virus, first described by Smith[1], received little further attention until the beet ringspot virus, reported by Harrison[2], was found to be serologically related to it and to potato bouquet virus[3,4]. Smith and Short[5] later isolated a strain of tomato black ring virus from lettuce and named it lettuce ringspot.

Celery yellow vein virus, isolated from celery in 1957[6], also proved to be serologically related to strains of tomato black ring virus, and partly protected against them in plants. Celery yellow vein virus differed from other strains of tomato black ring viruses in host-range and symptoms, and in its antigenic behaviour *in vivo*, as reported here.

Celery yellow vein, tomato black ring and beet ringspot viruses were cultured in *Nicotiana clevelandii* Gray, in which they reach a high concentration within 14 days[7], and were assayed in *Gomphrena globosa* L., which produces local lesions within 7 days[8].

All three viruses could be partially purified and concentrated in several ways: by precipitation with ammonium sulphate or ethanol, by differential centrifugation, by the butanol-chloroform method of Steere[9] or a modification of it[10]. Each method yielded preparations which were highly infective, contained many 'spherical' particles (about 30 mμ diameter when examined in the electron microscope), produced clearly defined light-scattering zones in density-gradient centrifugation in sucrose columns, and reacted specifically with antiserum to beet ringspot virus.

Whereas all preparations of beet ringspot virus were highly antigenic when injected into rabbits (serum titres up to 1/2,500), no celery yellow vein virus preparation induced any specific antibody formation. Injection schedules included six graded intravenous injections at 4-day intervals, and two to four intramuscular injections at 2-week intervals using Freund's complete adjuvant.

The modification[10] of Steere's method of purification gave preparations with the greatest infectivity, particle concentration, density-gradient zone intensity, and antigenicity *in vitro*: leaves (80–120 gm.) of *N. clevelandii* were gathered 14 days after infection and minced with 1·25 × wt./vol. of $M/20$ buffer (KH_2PO_4–Na_2HPO_4) pH 7·6, containing 0·1 per cent thioglycollic acid, and n-butanol added drop by drop to the expressed sap to give a final concentration of 8·5 per cent. The mixture was clarified by centrifuging for 25 min. at 12,500 r.p.m. in the $R30$ rotor of a Spinco model L preparative centrifuge. The supernatant fluid was filtered, and the virus sedimented for 2 hr. at 30,000 r.p.m. The pellets were re-suspended in about one-twentieth of the original sap volume of $M/30$ phosphate buffer, insoluble matter removed by brief centrifugation, and the colourless, slightly opalescent fluid used for the preparation of antiserum.

Preparations of some animal viruses have been treated with formalin to destroy infectivity, without apparently affecting their antigenicity when used as vaccines. Formalin was added to freshly prepared celery yellow vein virus preparations to give 0·2 per cent concentration, before injection into rabbits. Two intramuscular injections of 0·6 ml. and 1·25 ml. respectively of virus preparation, each emulsified with 1 ml. of Freund's complete adjuvant (Bacto), were followed 3 weeks later by an intravenous injection of 1·25 ml. of formalin-treated preparation. The serum obtained 4 weeks later, reacted specifically with purified preparations of celery yellow vein, tomato black ring and beet ringspot viruses, but not with control preparations from uninfected plants. The serum titre in precipitin tube tests against the homologous antigen was 1/1,520.

This difference in antigenic behaviour *in vivo* between strains of a plant virus has not apparently been reported before, and could not be correlated with any differences in virus concentration or *in vitro* stability.

This use of formalin-treated antigen does not appear to have been previously recorded, and may enable antisera to be prepared against some other plant viruses for which the standard methods have failed.

GENETICS

Controller Genes in Synthesis of Human Hæmoglobin

MOST current accounts of gene action stress protein production as the primary gene function. Structural and functional proteins alone, however, cannot account adequately for embryological differentiation and specialized cell function. Since all cells derived from one fertilized ovum share identical genetic material, control systems must exist which govern activation and inhibition of gene action to allow complex cell functions.

The chemical structure of normal adult hæmoglobin (Hb A) is $\alpha_2\beta_2$: 2α polypeptide chains and 2β polypeptide chains. A normal, electrophoretically slow hæmoglobin component, Hb A_2, is $\alpha_2\delta_2$, the δ-chain being a slightly modified β-chain. Normal fœtal hæmoglobin is $\alpha_2\gamma_2$, the γ-chain differing from the adult-type β-chain. The α-chain is identical in all these three normal hæmoglobins. Each of these polypeptide chains has been shown to be under independent genetic control, and mutations affecting their chemical structure have been found.

Recent observations on a human hæmoglobin mutant which apparently does not affect polypeptide structure sheds some light on the control of gene function and protein synthesis. This mutation manifests as the persistence of large amounts (15–35 per cent) of fœtal hæmoglobin[1,2] in otherwise normal adults, heterozygous for this trait. Fœtal hæmoglobin in these subjects is physicochemically identical to fœtal hæmoglobin of the new-born[3]. The condition is inherited as an autosomal trait. The term 'non-microcythæmic thalassæmia' has been applied to it by some investigators. Since other types of thalassæmia unrelated to the high fœtal hæmoglobin trait may be non-microcythæmic and since this trait appears to be different from thalassæmia (see below), this designation should be abandoned.

Children of individuals doubly heterozygous for (*a*) the high fœtal hæmoglobin trait and (*b*) the sickle cell (Hb S) trait[1,2] (or Hb C trait)[4] always inherit one or the other abnormality, but not both. Since the Hb S and Hb C gene are known to be mutations of the Hb β locus, the locus for the 'high fœtal hæmoglobin trait' can be assumed to be allelic or closely linked to the Hb β locus. Close linkage between the Hb β and the Hb δ loci has also been indicated, since children of individuals possessing (*a*) the sickling trait[5,6] (or high Hb F trait)[2] and (*b*) a mutant of the δ locus, Hb A_2 ($\alpha_2\delta_2{}^{A_2'}$—also known as Hb B_2), similarly inherit one or the other but not both abnormalities. The Hb α locus appears to be assorted independently from the β locus. No information on the linkage relations of the γ locus is available.

These data allow the construction of a tentative genetic map of the Hb β locus and related sites which aids in the explanation of gene action at this complex locus (Fig. 1). It is suggested that hæmoglobin synthesis by the linked and closely related Hb β and δ loci is regulated by an operator gene at an adjacent chromosomal site. The operator gene is inactive during early fœtal life, and no β- and δ-chains are synthesized. During fœtal development, the operator gene activates the expression of the adult-type β and δ-chains and, as a secondary effect, suppresses the production of fœtal type (γ) chains in a reciprocal relationship. The persistent fœtal hæmoglobin trait is considered a mutation of the operator gene, causing failure of normal activation of the β- and δ-chains. Continued production of fœtal γ-chains ensues. A patient homozygous for the Hb F syndrome had only Hb F ($\alpha_2\gamma_2$) and no Hb A ($\alpha_2\beta_2$)[8,10]. Absence of β-chain synthesis under control of the mutant chromosome is also clearly demonstrated in individuals doubly heterozygous for the high fœtal Hb trait and Hb β locus mutations (such as Hb S or Hb C). In such patients, hæmoglobin analysis shows approximately 70 per cent Hb S ($\alpha_2\beta_2{}^S$)[1,2,4] or 70 per cent Hb C ($\alpha_2\beta_2{}^C$)[2,4] and 30 per cent Hb F ($\alpha_2\gamma_2$). No normal hæmoglobin is found, indicating that no β-chains are produced under control of the chromosome with the 'operator' mutation. Evidence for suppression of the δ locus by the operator gene is suggested by low levels of Hb A_2 in the blood of newborns[9], decreased levels of Hb A_2 in high fœtal hæmoglobin heterozygotes[2,3], and by the complete absence of Hb A_2 from the blood of the high fœtal hæmoglobin homozygote[10]. The operator gene affects only the immediately adjacent linked β and δ loci of its own (*cis*) chromosome. Expression of the β and δ loci of the other non-mutant (*trans*) member of the chromosome pair is normal in heterozygotes with the high fœtal hæmoglobin trait, since Hb A ($\alpha_2\beta_2$) and A_2($\alpha_2\delta_2$) are both formed by such individuals.

Family data indicate that the most frequently encountered form of thalassæmia (β-thalassæmia) also is linked to the β locus[5]. In this type of thalassæmia there again is marked suppression of β-chain production. This β-chain suppression, however, is usually less complete than in the high fœtal hæmoglobin trait since thalassæmia homozygotes, sickle-thalassæmia double-heterozygotes, and high Hb F-β-thalassæmia double heterozygotes[2,10] frequently produce some normal hæmoglobin ($\alpha_2\beta_2$) with β-chains. In contrast to the high fœtal hæmoglobin trait, Hb A_2 is relatively elevated in β-thalassæmia heterozygotes, indicating that δ-chain formation is not suppressed and may even be absolutely increased. β-thalassæmia, however, severely interferes with total effective hæmoglobin formation by the erythropoietic cell and the relative failure of β-chain production is only partially and unsuccessfully compensated by γ-chain formation. In contrast, in the high Hb F trait total effective Hb synthesis is only slightly impaired since this condition represents failure of normal activation of adult type hæmoglobin chains with persistence of the normal physiological mechanism for fœtal chain production. The one known homozygote for the high Hb F trait was clinically normal with normal total hæmoglobin even though all the hæmoglobin was of the fœtal ($\alpha_2\gamma_2$) variety[10]. In β-thalassæmia, the marked depression of β-chain synthesis with unsuccessful compensation by γ-chain production and the sparing of the δ locus indicate a different kind of mutation. Several authors suggested that β-thalassæmia is caused by an electrophoretically undetectable mutation[11] of the β locus, but such a theory has not yet been proved[12]. As an alternative hypothesis, Ingram[13] suggested the existence of a 'tap', a chromosomal region linked to the Hb β locus, controlling the rate of β chain production. In β-thalassæmia, mutations of the 'tap' would lead to relative failure of β-chain production. The biochemical and functional relationship of the postulated 'tap' gene to the 'operator' gene remains unknown. Whatever the exact mechanism in β-thalassæmia, the findings in the high fœtal Hb trait are a clear indication of the operation of a discrete control system in mammalian protein synthesis.

	Operon			
	Controller genes		Structural genes	
	'Operator' gene	'Tap' gene	Hb β gene	Hb δ gene
Normal function	Activates β and δ chain formation during later fœtal life and, as a secondary effect, inhibits γ-chain formation in a reciprocal relationship.	Controls rate of β-chain synthesis.	β_2 chain production	δ_2 chain production
Mutants :	High Hb F trait : Mutation of the operator gene causes failure of Hb β and δ activation and, therefore persistent production of γ chains.	β-thal-assemia	Hb S,C,E etc.	Hb A_2' (Hb B_2)

Fig. 1. Tentative genetic map of the Hb β gene and related sites. Family data indicate linkage of the β locus to the loci for Hbδ, high fœtal Hb trait and β-thalassæmia. The linkage relationship of the various sites of this gene complex to each other is postulated. Evidence for the existence of the 'operator' gene is stronger than that for the 'tap' gene

Certain analogies between the control mechanisms of hæmoglobin synthesis and current concepts of the control of protein synthesis in microbial systems are striking. Data on mutants affecting enzyme production and repression in *E. coli* have led Jacob *et al.* to formulate a concept of structural genes concerned with protein synthesis and controller genes modulating such protein synthesis[14]. The controller genes in the microbial system are not affected by agents which block protein synthesis and their gene products presumably are not proteins. Various data suggest that the genetic control system comprises 'regulator' genes producing repressor substances and 'operator' genes which switch on and off the expression of several linked and functionally related genes to which the operator gene is also linked. The group of functionally related genes affecting a given sequence of metabolism has been called the 'operon'. The regulator genes may or may not be linked to the 'operon'.

Applying such a concept to the above data, a hæmoglobin operon may be postulated which is made up of the operator gene linked to, and controlling, the adjacent structural Hb β and δ loci (Fig. 1). In both the microbial and hæmoglobin systems the data indicate that expression of the immediately adjacent (*cis*) operon only, and not of the operon on the other (*trans*) member of the chromosome pair, is affected. An additional feature of the hæmoglobin control mechanism is the role of the Hb operator gene during embryonal development in activating the synthesis of a different type of adult protein chain. The functional need for this activation is not obvious since the only homozygote for the persistent fœtal hæmoglobin trait is apparently in good health. Furthermore, a successful mammalian species, the horse, lacks the fœtal-adult hæmoglobin switch[15]. Continued study of these and similar control systems of protein synthesis should help in understanding the integrated gene function necessary for differentiation and cell function in complex organisms such as man.

Gene Expression in Heterozygotes

IN many cases a gene appears to function only by synthesizing a polypeptide chain through the mediation of ribonucleic acid (RNA), and hence controlling the synthesis of a protein. A mutation may cause a different polypeptide chain to be synthesized, for example, in the hæmoglobinopathies, or may result in failure to produce a polypeptide chain at all. In man there is little variation, in most individuals, of the concentration of each of the various proteins in the body fluids. This suggests that the rate of synthesis of each protein is controlled by the concentration already present. If this is so, a process of feed-back repression must operate. This may be at gene-level, perhaps resembling the regulator gene and repressor mechanism of bacteria[1], or at RNA-level. It is suggested that, in suitable cases, a study of the concentration of a protein or enzyme in the heterozygote may help to decide which type of mutation is involved.

An example is provided by analbuminæmia and bisalbuminæmia. In analbuminæmia the abnormal homozygote has no albumin or albumin-like protein in the blood, but the heterozygotes have normal concentrations of normal albumin[2]. In bisalbuminæmia the abnormal homozygote has not as yet been detected; the heterozygote has roughly equal concentrations of typical and atypical albumins in the blood, the sum of the two being equal to the normal concentration of albumin[3]. In analbuminæmia the heterozygote has one silent gene and one normal gene; it is suggested that the feed-back repression of albumin synthesis responds to the concentration of albumin in the blood and, in consequence, synthesis of albumin by the normal gene is not inhibited until this concentration is normal. On the other hand, in the heterozygote for bisalbuminæmia, the two albumins are so similar that feed-back repression responds to both typical and atypical albumins and, in consequence, the activity of both the normal and the mutant genes is inhibited when the concentration of typical albumin is only about half the normal concentration.

A second example is provided by cases of hæmophilia studied by Graham *et al.*[4,5]. Hæmophilia (hæmophilia *A*) can be severe or mild; in severe hæmophilia virtually no antihæmophilic globulin (*AHG*) activity can be detected in the blood; in mild hæmophilia *AHG* activity is far below normal but is measurable. The mothers of severe hæmophilics were found to have normal *AHG* activity in their blood, the mothers of mild hæmophilics to have *AHG* activity between the normal and hæmophilic levels. In both cases the mothers have one normal gene and one gene for hæmophilia.

It is suggested that, in these cases of mild hæmophilia, the mutant gene causes the synthesis of some protein only slightly different from antihæmophilic globulin and that this new protein has relatively slight *AHG* activity. Heterozygotes for mild hæmophilia would then synthesize normal *AHG* and some *AHG*-like protein in roughly equal amounts. If the rate of production of *AHG* in the homozygous normal is controlled in some way depending on the concentration of *AHG* in the blood, by a process of feed-back repression, and the regulating mechanism cannot distinguish between *AHG* and the *AHG*-like protein, only half the normal amount of *AHG* will be synthesized.

By an extension of this argument, it is suggested that in severe hæmophilia the mutant gene is either silent, that is, produces no protein at all, or produces a protein so different from *AHG* that the regulatory mechanism does not respond to it. In heterozygotes the feed-back repression of *AHG* synthesis would respond only to the *AHG* produced by the normal gene, therefore synthesis of *AHG* would not be inhibited until its concentration in the blood reached normal levels. This mechanism would also explain why the hemizygous male has *AHG* activity in his blood equal to that of the normal female[6].

In some cases of severe hæmophilia the carriers have reduced *AHG* activity in their blood[7-9]. Possible explanations are: (1) that the mutant gene in these cases causes the synthesis of a protein devoid of *AHG* activity but sufficiently similar to *AHG* to affect the regulatory mechanism; or (2) that the regulatory mechanism itself is at fault; or (3) that present methods of determining *AHG* activity do not measure the true concentration of a single molecular species. There is some immunological support for alternative (1)[10].

Yet a third example is pseudocholinesterase deficiency. Kalow[11] has demonstrated that, in most cases of pseudocholinesterase deficiency, the homozygote has an atypical enzyme of low activity in his plasma while the heterozygotes have pseudocholinesterase activities between the normal and homozygote levels, with a mixture of typical and atypical enzymes. Recently a family has been found with a silent gene[12]; the homozygote has neither typical nor atypical pseudocholinesterase in his plasma, but the heterozygote has pseudocholinesterase activity in the normal range. This suggests that the silent gene is producing nothing that can cause feed-back repression of pseudocholinesterase synthesis, hence the normal gene in the heterozygote produces about as much pseudocholinesterase as is present in the homozygous normal. On the other hand, atypical pseudocholinesterase produced by the more usual type of mutant gene affects the regulatory mechanism, causing the heterozygote to have low concentration of typical pseudocholinesterase.

Apart from circulating proteins, there is some evidence that a similar state of affairs may exist in galactosæmia[13]. Phenylketonuria exists in 'mild' and 'severe' forms[14], and family studies are being carried out to see whether the hypothesis advanced here can apply to phenylketonuria.

I thank Sir George Pickering for a helpful discussion, and Dr. H. Lehman for unpublished information on cholinesterase deficiency.

ANTHROPOLOGY

Age of Basalt underlying Bed I, Olduvai

I have received a copy of the communication by Drs. von Koenigswald, Gentner and Lippolt, on the age of the basalt flow at Olduvai[1]. This article contains certain mis-statements, which seem to be the result of overlooking reports between 1951 and 1960 and quoting from out-of-date chapters of my book on Olduvai[2].

Drs. Gentner and Lippolt have apparently used three specimens.

(*a*) A specimen collected by Oakley in 1947, which they use without any indication of whereabouts in the Gorge it was collected. It must, I think, represent a specimen from the weathered and exposed surfaces of the basalt on the floor of the Gorge, since in 1947, when Oakley visited Olduvai for a few hours, he had no means of access to the underlying lava at places where it is sealed in by the overlying beds.

(*b*) The other two specimens used were tools of Oldowan type collected when von Koenigswald visited Olduvai with me in 1951. I made it quite clear to him at the time that these were surface specimens and might have come from Bed I, but equally from anywhere up to the top of Bed IV, since, typologically, Oldowan tools continued to be used right to the top of the sequence, although in Bed I they are characteristic, and in Bed II, at the base, predominate over all other types.

These two specimens were only given to von Koenigswald as representative examples of the shape and form of the Oldowan type of tool and certainly not as representing *in situ* Bed I material for dating purposes; so far as Bed I is concerned, they are irrelevant, since they may have been tools used in mid-Pleistocene times and made from mid-Pleistocene lavas, or anything earlier.

The three authors also discuss the age of Bed I on the basis of the fossil fauna, but, in this context, quote nothing more recent than Hopwood's out-dated lists in my 1951 volume on Olduvai. I have made it clear on a number of occasions, since then, that this is out of date and inaccurate.

The three authors correctly state "after the discovery of *Zinjanthropus*, however, Leakey included Bed I in the Lower Pleistocene", but they ignore the fact that I have given reasons in various places for doing so, and that, in fact, I suggested a Lower Pleistocene date as far back as 1935, although I temporarily withdrew this in 1951 because Hopwood had wrongly identified some of the fauna and so misled me.

A lengthy three-volume report on the fauna and other aspects of the Olduvai work will shortly be going to press. I must state, however, that there is no trace whatsoever of *Elephas* (*antiquus*) *recki* in Bed I where the characteristic elephant is *Elephas* cf. *africanavus* of the Villafranchian of North Africa. Even at the base of Bed II I have not, so far, found *Elephas* (*antiquus*) *recki in situ* but only *Elephas exoptatus* (or cf. *meridionalis* of Arambourg).

Indeed, far from what Hopwood claimed, the fauna of Bed I, in so far as its very numerous large mammals are concerned, is more than 95 per cent extinct.

There is abundant faunal as well as geological evidence to indicate a time-break between Bed I and Bed II and, moreover, I have indications that the base of Bed II is different from the top of Bed II; with the base of Bed II probably of the same age as the Omo fossil beds. There is also a distinct difference between the fauna of the lower and middle part of Bed I and the top of Bed I.

Bed I is not "30 metres thick". It has such a thickness in places and varies from as little as 18 ft. to more than 100 ft. In the area of the *Zinjanthropus* sites it is about 40 ft. thick. The authors repeatedly restate the wholly out-dated suggestion that the fauna of Bed I and Bed II is roughly the same, which is quite incorrect.

Samples of the lava, which underlies the Olduvai deposits at site *FLK* I and other sites, are being studied by Curtis and Evernden and I am asking them to reply independently to this aspect of the communication by von Koenigswald, Gentner and Lippolt.

---

[1] *Nature*, 192, 720 (1961).

[2] Leakey, L. S. B., *Olduvai Gorge* (Camb. Univ. Press, 1957).

In Dr. Leakey's reply to our communication I miss his answer to our main question: What is his date for the basalt of Olduvai ?

After Dr. Curtis's cautious remarks early in 1961[1] about the age determinations from Olduvai—"However much of that section is contaminated . . . I think the thing to do is to get a sequence of dates and throw out those that are vastly anomalous"—I did not expect such categorical statements shortly afterwards. I am fully aware of the difficulties, but just as the results seem to indicate a so much greater age than expected I feel that all sources of possible errors and the sedimentological implications should be fully discussed before they are accepted.

So far as the fauna is concerned, I am surprised that Dr. Leakey now rejects Dr. Hopwood's determinations which he included in 1951 in his book *Olduvai Gorge*. Dr. Leakey stated that certain species are restricted to Bed I; Beds I and II still have in common such archaic genera as *Dinotherium*, *Mastodon* and even *Australopithecus*[2]; this could scarcely be expected if such a major break existed between Bed I and Bed II as suggested by Dr. Leakey.

It is, in connexion with the time-factor, interesting to learn the Oldowan tools, typologically, continue to the top of the sequence. But who is responsible for the Oldowan culture *s. str.* ? Quoting Dr. Leakey[3]: "In my report to *Nature* on the discovery of the skull of *Zinjanthropus boisei* at Olduvai Gorge in 1959, I made it clear that I believed that the very close association of quantities of primitive Oldowan stone tools with the skull of *Zinjanthropus* . . . suggested that it represented the makers of this culture. I admit, that I am no longer quite so certain, but I still think that in all probability . . . "

[3] Leakey, L. S. B., *Progress and Evolution of Man in Africa*, 44 (Oxford Univ. Press, 1961).

The age of 1·75 million years obtained by us for early man at Olduvai Gorge has been questioned by von Koenigswald, Gentner and Lippolt on the basis of their determination of an age of 1·3 million years for the basalt underlying the strata containing the hominid remains.

While at the Gorge in April 1961, one of us (G. H. C.) examined the basalt carefully for dating purposes. In most exposures, however, the basalt shows effects of chemical alteration and is clearly not suitable for obtaining reliable ages. Nevertheless, three specimens were sent here for examination. Thin-section examination revealed that none of these was suitable for dating; but with the appearance of the above-mentioned communication we chose the best two specimens and made age determinations in order to compare the numbers.

Specimen *KA* 927 was collected by Leakey at Site *FLK* I and specimen *KA* 933 was collected by Curtis at the third vault. *KA* 927 is an olivine basalt exhibiting subophitic or intergranular texture with numerous phenocrysts of olivine up to 1 mm. in length in a groundmass of titanaugite and plagioclase. The plagioclase laths average about 0·4 × 0·1 mm. but vary considerably, while the titanaugite is more nearly equidimensional and averages about 0·2 mm. in diameter. Grains of ilmenite compose about 5 per cent of the rock. Some of the sparse vesicles are filled with calcite, and a carbonate is intergrown with plagioclase and titanaugite in the groundmass in a manner suggesting that it is a primary mineral. Most of the margins of the titanaugite are chloritized, and chlorite or a serpentine mineral replaces the margins and cleavage cracks in most of the olivine[1]. Even some plagioclase grains are extensively chloritized.

Specimen *KA* 933 was probably an olivine basalt or olivine trachyte, but the few phenocrysts of olivine have since been completely converted to iddingsite. In other respects, however, the specimen appears less altered than *KA* 927 and no chlorite is present. The rock is exceedingly fine-grained though holocrystalline. The average plagioclase is approximately 0·05 mm. in length and less than 0·01 mm. in width. A few plagioclase phenocrysts attain 1·5 mm. Intergranular clinopyroxene averages approximately 0·01 mm. in diameter, but a few grains reach 0·2 mm. Dark brown and black equidimensional grains of magnetite and hæmatite averaging 0·01 mm. in diameter are so abundant that they render the thin-section opaque in 30μ thickness. Only thin edges of 10μ or less in thickness can be examined in transmitted light. The grains of magnetite and hæmatite occur along margins, in centres, and in zones within the plagioclase. A striking feature of the rock is the presence of biotite both in the groundmass and extending out from the sides of very numerous micro-vesicles. Some biotite flakes are up to 0·5 mm. in length. Many vesicles are partly coated with calcite.

The proportions and types of minerals are different in the two specimens, and it appears unlikely that they are specimens of the same flow. The difference in potassium contents supports this view. As two superimposed flows can be seen at one of the exposed faults in the Gorge, the occurrence of two different types at widely spaced localities is not surprising.

The data that we have obtained on these two specimens are given in Table 1.

We conclude that the basalts at Olduvai are at least four million years old but that they are unreliable for dating purposes. There is thus no conflict between the dates obtained on the overlying tuffs and the best estimate of the age of the underlying basalts. There are good reasons why one should question the reliability of dates obtained on these basalts. The location of potassium in basalts is not known with certainty. Some is contained within the plagioclase and trace amounts go into the pyroxene. Probably in most cases potassium is concentrated in the final intergranular hydrous siliceous fluid where it either enters the albitic rims of the plagioclase or, in the case of

Table 1

KA	Weight (gm.)	Percentage K	Percentage A^{at}_{40}	Ar_{40}/K_{40}	Age (m y.)
927	32 19	0 876	92	2 37 × 10^{-4}	4·1 ± 0 5
927 (repeat)	16·46	0 876	97	2·32	4 0 ± 1·0
927 (repeat)	18·34	0 876	80	2·56	4·4 ± 0 2
933	21·16	1 472	90	1·00	1·7 ± 0 2
933 (repeat)	18·77	1 472	89	1 00	1·7 ± 0 2

specimen *KA* 933 above, forms late potassium-bearing minerals in the interstices of other minerals or in the vesicles. Any later chemical alteration of the rock attacks these grain-boundary areas first and the resultant loss of radiogenic argon may considerably reduce the age obtained. Several basalts which we have attempted to date from elsewhere, such as the Columbia River area and the Berkeley Hills, have yielded anomalously low ages, and we can only explain them along the foregoing line of reasoning. In view of the difficulty that we had in obtaining moderately fresh basalt from Olduvai Gorge, it appears unlikely to us that Gentner's specimen, obtained from the British Museum by von Koenigswald and collected by Oakley without this objective in view, is as reliable for dating as ours.

Equally significant may be the extremely fine-grain size of *KA* 933. Though average dimensions are given above for grain sizes, much of the rock is so fine-grained that individual crystals appear only as specks of light, that is, sufficient only to attest to the crystalline rather than glassy nature of the groundmass. The effective grain-size for argon diffusion is no doubt much greater in volcanic glass than in this rock. The rock carries about 5 per cent biotite so that only about 20 per cent of the potassium of the rock is in this mineral with the remainder probably being in the albitic rims of the plagioclase crystals. These crystals have an average width of less than 0·01 mm. with the result that most of the potassium is within less than 1μ of a grain boundary. Even this unattractive situation is rendered worse by the fact that these crystals are charged with magnetite and hæmatite. It is not certain that such inclusions will adversely affect argon retention, but it is certain that they will reduce the average distance to grain boundaries to less than one micron and will introduce strains into the feldspar lattice. Quantitative treatment of the indicated diffusion problem is impossible due to the uncertainties of some of the parameters, but approximate solutions indicate that the diffusion coefficient necessary to explain the observed losses is probably reached at the surface temperatures of the Earth.

Some of the arguments used by von Koenigswald *et al.* require further discussion and clarification. Gentner raises the question of inherited argon in the samples of tuff used by us. While one cannot be absolutely certain that inherited argon is not a problem in some rocks, certain definite statements can be made. All available data on argon diffusion in feldspars indicate that argon retention in feldspar crystals suspended in molten rock is essentially zero over time spans of even a few days. We can state that the few volcanic sanidines of historic age dated by us have yielded ages consistent with the concept of zero argon content at the time of eruption. Both the 1912 eruption of Katmai and the 1304 eruption of Ischia yielded zero potassium/argon ages. Also, dates of late or post Pleistocene events have given reasonable ages. A late Gamblian tuff from Lake Naivasha in Kenya gave 28,000 years and a prehistoric post-glacial pumiceous rhyolite dome near Mono Lake, California, gave 5,600 years.

If the possibility of faulty stratigraphic correlation can be eliminated, the most probable source of error in any tuff lies in the possibility of contamination from older admixed debris, whether erosional debris or country rock torn from the sides of the conduit at the time of eruption. The Olduvai tuffs were examined carefully for such material before being used. The mineral used would virtually eliminate any possibility of significant conduit contamination, and the nature of the deposits (that is, primary tuff falls) argues strongly against any admixture of eroded debris. We see no possibility of explaining the tuff ages in terms of admixed older anorthoclase crystals.

The only sample of post-Pleistocene feldspar that has yielded an age far older than that assigned to it by field investigators is the concentrate of Laacher See sanidine sent to us by Dr. Frechen, University of Bonn. We have made several runs on this material, and all ages obtained are several hundred thousand years rather than the 11,000 years suggested by its assignment to Allerod. As we had nothing to do with the collection or concentration of this material, we are in no position to explain the gross discrepancy. However, we feel that the diffusion data and the dates from other young samples argue so positively for total argon loss at temperatures of 1,000° C. that we must conclude that the Laacher See sample is either contaminated or misplaced stratigraphically.

von Koenigswald appears concerned about the slow rate of sedimentation in Bed I and believes that every trace of bone would have disintegrated before becoming sufficiently buried. This opinion is based on a complete misconception as to the nature of sedimentation at Olduvai. Virtually all the layers in Bed I are primary tuffs, that is, ash falls directly from the air. They instantly buried everything lying on the land surface or in the shallow margins of the lake. One of these ash-fall units is 12 ft. thick.

Again in response to an objection of von Koenigswald, it is to be noted that the tops of many of these ash-fall layers show well-developed soil profiles, some of them quite deep (up to 4 ft.) and indicating protracted periods of time of development. Each of these soil profiles indicates a disconformity. The soil profiles are numerous, well-developed, and plainly visible in quarry faces though not in weathered canyon-wall views. It may come as a surprise to many to learn that the stratigraphy of such an important locality as Olduvai Gorge is very imperfectly known. The only reference describing Bed I (*Olduvai Gorge Monograph*, Leakey *et al.*) does not even mention the crystal content of the tuffs though this content may make up more than 30 per cent of the rock. This reference does not mention the existence of soil profiles and virtually implies absence of them. The large cuts made in conjunction with the *Zinjanthropus* excavations now clearly display an extensive development of soil profiles. This lack of adequate description of the Olduvai section will be remedied shortly as the tuffs are being studied by a competent volcanologist.

In conclusion, it can be stated that the basalts at Olduvai are at least four million years old, and that the result obtained by Gentner is to be interpreted as the result of using unreliable material. In addition, the soil profiles sought by von Koenigswald are present in profusion, and his bone destruction hypothesis is invalid on the grounds of inadequate understanding of the mechanism of tuff accumulation at Olduvai. All data so far available agree that there is no alternative to accepting an age for *Zinjanthropus* and for Lower Pleistocene of approximately two million years.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, May 14

UNIVERSITY OF LONDON (at the Wright-Fleming Institute of Microbiology, St Mary's Hospital Medical School, Paddington, London, W.2), at 5 p m —Dr. J. L. Gowans "The Role of Lymphocytes in Immunological Reactions".* (Second of four Almroth Wright Lectures.)

BRITISH SOCIETY FOR THE HISTORY OF SCIENCE (at the Science Museum, Exhibition Road, London, S W.7), at 5.30 p.m —Mr A. W. Badcock. "Physical Optics at the Royal Society to 1800".

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 6 p.m.—"Adventure in Nepal", Colour films with commentary by Mr J. B. Tyson.

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m —Mr. J. Macdonald· "Forestry". (Second of three Cantor Lectures on "The Development of Natural Resources".)

INSTITUTION OF ELECTRICAL ENGINEERS, LONDON GRADUATE AND STUDENT SECTION (at Savoy Place, London, W.C.2), at 6.45 p.m.—Annual General Meeting, followed by Dr H. G. Taylor: "The Work of the Electrical Research Association".

Tuesday, May 15

UNIVERSITY OF LONDON (at the Institute of Obstetrics and Gynæcology, Hammersmith Hospital, London, W.12), at 2 p.m —Prof. P. Polani "Human Chromosomes and their Abnormalities".*

INSTITUTE OF PETROLEUM (at 61 New Cavendish Street. London, W.1), at 5 p.m.—Mr Julian M Leonard: "Petroleum—a New Concept in the Field of Chemical Manufacture" (Presidential Address)

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS AND COMMUNICATIONS SECTION (at Savoy Place, London, W.C 2), at 5 30 p.m. —Mr. R. F. Purton "A Survey of Telephone Speech-Signal Statistics and their Significance in the Choice of a P.C.M. Companding Law".

SOCIETY OF CHEMICAL INDUSTRY, AGRICULTURE GROUP (at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Annual General Meeting and Chairman's Address.

Wednesday, May 16

UNIVERSITY OF LONDON (at the Institute of Diseases of the Chest, Brompton Hospital, London, S.W 7), at 5 p m.—Dr. R. W. Riddell: "The Bacteriology of Mycobacterial Disease".*

ROYAL STATISTICAL SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m —Dr. D. J. Finney. "The Statistical Evaluation of Educational Allocation and Selection".

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS AND COMMUNICATIONS SECTION (at Savoy Place, London, W C 2), at 5.30 p.m —Dr. E Eastwood: "Radar Observations on Bird Migration".

BRITISH INSTITUTION OF RADIO ENGINEERS, MEDICAL ELECTRONICS GROUP (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6 p.m.—Mr. K. Lloyd-Williams, Mr. F. Lloyd-Williams, Mr. C. M. Cade and Mr. C. J. Hart. "Infra-Red Radiation Thermometry in Clinical Practice".

Thursday, May 17

INSTITUTION OF MINING AND METALLURGY (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 4 p.m.—Annual General Meeting. Mr. J. B. Simpson. "Security in the Mining Profession" (Presidential address).

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Prof. F. G. Young, F.R.S. "On Insulin and Its Action" (The Croonian Lecture).

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p m.—Annual General Meeting. 6.30 p.m.—Dr. F. T. Farmer. "Some Aspects of the Application of Electronics to Medicine".

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—Dr. R. B. Heisch. "Feral Aspects of Rickettsial Infections in Kenya".

Friday, May 18

INSTITUTE OF NAVIGATION (at the Royal Institution of Naval Architects, 10 Upper Belgrave Street, London, S.W.1), at 5.30 p.m. —Meeting on "The Navigation of Hovercraft".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m —Dr. H Lowery "On Making Music".

Monday, May 21

INSTITUTION OF THE RUBBER INDUSTRY (at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 4 p.m.—Prof. G. Stafford Whitby. "The Biogenesis of Rubber—How the Tree Makes Rubber" (Seventeenth Foundation Lecture).

UNIVERSITY OF LONDON (at the Wright-Fleming Institute of Microbiology, St. Mary's Hospital Medical School, Paddington, London, W.2), at 5 p.m.—Dr. A. Isaacs: "The Antiviral Action of Interferon"* (Third of four Almroth Wright Lectures).

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Dr. H. Cole: "Fisheries". (Last of three Cantor Lectures on "The Development of Natural Resources").

INSTITUTE OF METAL FINISHING (at the Northampton College of Technology, St. John Street, London, E.C.1), at 6 15 p.m.—Mr I A. Menzies. "The Electrodeposition of the Less Common Metals"

SOCIETY FOR VISITING SCIENTISTS (at the English Speaking Union, Dartmouth House, 37 Charles Street, London, W.1), at 7.30 p.m —Discussion Meeting on "The Turkey X Disease". Chairman Prof. Alexander Haddow, F.R.S. Speakers· Dr. P. C. Spensley, Dr. J. M. Barnes and Mr. J G. Carnochan.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned.

RESEARCH ASSISTANTS (2) (with either a science or medical degree, and preferably a knowledge of cytology and sterile techniques), for work in connexion with cancer research at the Chromosome Unit of the Liverpool Radium Institute—The Registrar, The University, Liverpool 3, quoting Ref. CV./69/N (May 19).

HEAD (highly qualified) OF THE DEPARTMENT OF PHYSICS—The Principal, College of Advanced Technology, Gosta Green, Birmingham 4 (May 22)

ASSISTANT TRIALS OFFICER (with a degree in botany, agricultural botany or agriculture), to work at the Regional Trials Centre at Leeds University Farm, Headley Hall, Yorks—The Secretary. National Institute of Agricultural Botany, Huntingdon Road, Cambridge (May 23).

ASSISTANT LECTURER IN PHYSICS—The Secretary, Queen Elizabeth College (University of London), Campden Hill Road, London, W.8 (May 25).

SENIOR LECTURER and a LECTURER (preferably with qualifications in applied mathematics or geometry) IN THE DEPARTMENT OF MATHEMATICS, University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (May 25).

SENIOR LECTURER IN GEOGRAPHY at the Port Elizabeth Division of Rhodes University, South Africa—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa and London, May 25).

ASSISTANT CURATOR IN GEOLOGY in the Hunterian Museum—The Secretary of University Court, The University, Glasgow (May 26).

ASSISTANT IN GEOLOGY in the Hunterian Museum—The Secretary of University Court, The University, Glasgow (May 26).

ASSISTANT or a LECTURER (with qualifications in palæontology, including stratigraphical palæontology) IN GEOLOGY—Secretary of University Court, The University, Glasgow (May 26).

LECTURER or ASSISTANT LECTURER (with a knowledge of stability and control of aero-elasticity) IN THE DEPARTMENT OF AERONAUTICS AND ASTRONAUTICS—The Secretary and Registrar, The University, Southampton (May 26).

LECTURER or ASSISTANT LECTURER (with a recognized honours degree or equivalent and experience in teaching and research) IN THE DEPARTMENT OF BOTANY, University of Malaya—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Malaya and London, May 31).

LECTURER or ASSISTANT LECTURER (preferably with a knowledge of either colloid or surface phenomena) IN THE DEPARTMENT OF CHEMICAL ENGINEERING—The Deputy Registrar, The University, Edgbaston, Birmingham 15 (May 31).

PROFESSOR (of high academic standing and specialized in some branch of pure or applied mathematics or theoretical physics) OF MATHEMATICS at the University of Natal, Durban, South Africa—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa and London, May 31).

SENIOR LECTURER (physicist with a Ph.D. degree, extensive experimental experience in electronics, and interested in plasma physics) IN THE DEPARTMENT OF NATURAL PHILOSOPHY—The Secretary, Royal College of Science and Technology, George Street, Glasgow, C 1 (May 31).

TUTORIAL FELLOW IN PHILOSOPHY—The Senior Tutor, University College, Oxford (May 31).

FELLOW, and a RESEARCH FELLOW, IN THE DEPARTMENT OF BIOCHEMISTRY, John Curtin School of Medical Research, Institute of Advanced Studies, Australian National University—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, June 4).

ASSISTANT LECTURER (preferably with a special interest in biogeography or surveying) IN THE DEPARTMENT OF GEOGRAPHY, University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C 1 (June 5)

LECTURER (preferably with a special interest in micro-palæontology and/or palynology) IN GEOLOGY at the University of Canterbury, New Zealand, to assist in the teaching of palæontology and historical geology—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, June 15)

MASTER TO TEACH CHEMISTRY in the Sixth and Fifth Forms—The Headmaster, Bolton School, Bolton, Lancs.

MIRRLEES-NATIONAL RESEARCH FELLOW (with a good honours degree in engineering and some research experience) IN THE DEPARTMENT OF MECHANICAL ENGINEERING in the Faculty of Science, to undertake research in combustion in reciprocating engines in accordance with a prearranged programme of work—The Registrar, The University, Manchester 13 (July 1).

HEAD (with a good honours degree and teaching experience) OF THE PHYSICS DEPARTMENT; and a MATHEMATICS MASTER and a PHYSICS MASTER—The Headmaster, St. Albans School, Abbey Gateway, St. Albans, Herts.

READER IN THE DEPARTMENT OF PHYSICS—The Clerk to the Governors, Chelsea College of Science and Technology, Manresa Road, London, S.W.3.

SCIENCE AND THE NATIONAL ECONOMY

IN his Bernard Dyer Memorial Lecture to the Society of Analytical Chemistry in Manchester on March 7, Dr. D. W. Hill, dealing generally with research and the national economy, pointed out that in 1958–59, out of a total expenditure in Great Britain on civil research of some £200 million, £23 million went to the universities mainly for fundamental research, £8 million to the research associations for fundamental and applied research, as well as technical services to industry, £124 million to private industry for research and development, and £46·5 million for Government research stations for a wide range of research and other activities of general importance to the economy. The Government's contribution to this expenditure amounted to £80 million, of which £20 million went to the universities, £1·7 million to the research associations, £12 million to private industry, usually through research contracts, and £46·5 million to its own establishments.

Dr. Hill, without challenging the need to support fundamental research or considering whether the present support for such research was adequate, argued that the resources at present devoted to technological research were inadequate. Support for fundamental research was essentially an investment in the next generation, but both fundamental and applied research were vital to the scientific effort as a whole. They were also interdependent and each was liable to suffer from deficiencies in the other. With expenditure on research approaching 2·5 per cent of the gross national product, it was important to ensure that the distribution of this effort was properly balanced, particularly since the development of a project from the fundamental investigation into a commercial project was an extremely expensive undertaking.

It might be assumed that the universities were in 1958–59 spending the whole of their £23 million on fundamental research. For the research associations Dr. Hill suggested a figure of £2–3 million; for private industry about £12 million; and for Government research stations about £16 million; giving a total expenditure on fundamental research of rather more than £50 million. On Dr. Hill's figures, this leaves less than £150 million for all other forms of research and development, including technical services, an amount which, he suggested, could scarcely be considered sufficient to take full advantage of the expenditure on fundamental research, and if we were not to accept a reduction in expenditure on fundamental research, the balance could only be put right by increasing our expenditure on applied research and development.

Dr. Hill thought it was unreasonable to expect industry to increase its present contribution of £124 million a year in its own laboratories without the provision of specific incentives, whereas he believed that it would be relatively easy for direct Government assistance to be adjusted to the present needs. Directing attention to the comparatively small and steadily decreasing contribution from Government sources to the research associations, he asserted that a steady investment in research associations would result in a valuable return to the economy. Whereas in the early years the Government contribution was 70 per cent of the industrial contribution, in 1958–59 it had fallen to 28 per cent. While the income of the forty-six research associations operating in 1958–59 averaged £174,000, eight associations accounted for more than half the total expenditure; nine had incomes less than £50,000 a year, and a further fifteen incomes less than £100,000.

In concluding his lecture, Dr. Hill estimated that, with a present expenditure of some £8 million a year, the fifty-two research associations now operating were yielding returns to industry in direct and measureable benefits of more than £100 million. This aspect, however, was discussed more fully in an earlier lecture, last November, to the Manchester Statistical Society by Sir Harry Melville. Taking the expenditure on civil research and development in 1958–59 as some £243 million (out of a total expenditure on research and development of £478 million) or about 1·25 per cent of the gross national product, Sir Harry considered the Department of Scientific and Industrial Research, with an expenditure of a little more than £10 million, as the vehicle for the Government's investment in most fields of civil research and development except aircraft and nuclear energy, arguing that the Department's importance was in acting as a catalyst, inducing changes in the field of research and development which were out of all proportion to the actual expenditure.

Dealing briefly with the Department's provision of research grants and the work of its own research stations, Sir Harry Melville devoted much of his address to its support of the research associations, expressing the view that industry is prepared to finance an increasing volume of research and development within the associations. In the period 1949–58, the income of the forty-six research associations rose by 115 per cent, within which industrial contributions increased by 133 per cent, income from research contracts by 217 per cent, and the Department's own contribution by 53 per cent. In the period the amount of research work carried out by the associations is estimated as increasing by 52 per cent, while industrial production increased by 30 per cent.

Sir Harry Melville referred specifically to work of the Motor Industry Research Association and of the Research and Development Committee of the Timber Development Association to illustrate the way in which the work of the research associations pays off in returns to industry and the country's economy. He referred too, very briefly, to their educational function in the provision of technical and managerial staff, but neither he nor Dr. Hill examined the question of whether the research associations provided the most effective method of securing such results from the effort expended. It is this aspect that should be engaging the attention of the chairman of the Council of Scientific and Industrial Research in the review of the associations which the Minister for Science has requested.

That also can be said of the somewhat superficial policy statement, *Science in Government and Industry*, recently issued by the Association of Scientific Workers*. Starting from figures for expenditure on research and development in 1958, which agree with those taken by Dr. Hill and Sir Harry Melville, it urges that the Government should call for an increase in the allocation of money to research and development, strengthen the Ministry for Science and establish targets for the nationalized industries, making special grants for research where it can be shown that the revenue is insufficient to provide the money needed to reach those targets. Special measures are suggested for industries such as textiles and shipbuilding, including incentives to spend more on research, strengthening the research associations and the use of development contracts.

It is implied in the statement that at present Government expenditure is based on insufficient appreciation of the needs of the nation, though no supporting evidence is advanced, nor is there any critical examination of the decisive problem first of ensuring that research projects are well chosen and, secondly, that in the backward industries effective use is made of the results of research. It seems to be taken for granted that expenditure on research of itself will ensure development and the application of results. The possibility that research effort could be wasted or misdirected or that a point of no return could be reached does not appear to be considered; yet with Britain's limited resources, wise selection of projects, sound choice of method, are essentials to be determined before decisions are taken as to how much to spend on research.

The Association contends that the Ministry of Science is not fulfilling in some quarters the functions expected when it was first created, but with what justification it is difficult to determine in advance of the several inquiries into the deployment of our research effort which Lord Hailsham has already initiated. Apart from this, however, the statement inclines to accept without question the proposition that the State should intervene to support backward or declining industries by stimulating research or other means and not to face the alternative possibility that the healthier way for British economy as a whole would be to let the process of competition take its full course and allow such industries to decay, transferring labour to those industries in which Britain's greatest asset—the trained manpower and intelligence—are allowed full expression. We may well be paying already too high a price in supporting some industries too backward and too blind to help themselves.

The Association recognizes, nevertheless, that our last natural resource is manpower without drawing the appropriate deduction, and its assertions that in general we spend too little on research and development and that the distribution of this expenditure does not correspond to the need in various branches of industry are not supported by convincing evidence. Some sound suggestions are made, notably on the opportunity which the research association offers for organizing the most effective use of highly expensive equipment which a single institution or project could scarcely secure. The criticism of the low expenditure on research in the nationalized sector is probably well founded, more so than that of expenditure on educational research and research into health: the former is already being further encouraged by the Minister of Education, and on medical research the Association is at issue with official views that medical research suffers from lack of ideas rather than lack of funds. Undoubtedly, the statement indicates the importance of the review of the organization for the promotion of civil science by Government agencies which has now been initiated, and it also points to the urgency of the Advisory Council on Scientific Policy reaching early decision on its own inquiry into that field and ensuring that all the information required for sound decisions is available at the earliest possible moment.

ACADEMIC SCREWTAPE

Letters to a Vice-Chancellor

By James Dundonald. Pp. 109. (London: Edward Arnold (Publishers), Ltd., 1962.) 12*s*. 6*d*. net.

In *The Screwtape Letters* C. S. Lewis provides some brilliant and perceptive advice from an old experienced devil to a neophyte in devilry. In *Letters to a Vice-Chancellor* the don who hides his modesty under the name James Dundonald borrows this device (without, alas ! the brilliance or perception) to tell a newly appointed vice-chancellor to one of the newly founded universities what he ought to know.

The two books have one thing in common. If C. S. Lewis's Wormwood is as naive as he is made out to be, he will never make an efficient devil; and, similarly, if Dundonald's Sir Ronald Pellew (the new vice-chancellor) needs to be told some of the things which are included in *Letters to a Vice-Chancellor*, it is a poor prospect for the new University of Barstow which appointed him. James Dundonald's letters explain to Sir Ronald Pellew, ever so gently, that he must be patient when he presides over Senate meetings, because some professors are both prolix and irrelevant; that he must be at great pains to provide himself with an efficient registrar; that he must encourage his professors to take teaching seriously, and that he should persuade some of them to live on the 'campus' (the word has finally crossed the Atlantic), with a grant of £15 a year to pay for coffee and sherry parties for students; that he must not be too insistent on residence for all students; that he must play a sort of Russian diplomacy with the local technical college; and that over Sir Charles Snow and his two cultures the new vice-chancellor should look to Keele, and then try to improve on Keele's experiment.

All sound doctrine, no doubt. James Dundonald writes amiably and with tolerance. But he goes no deeper than the etiquette of running a university; the reader of this book might easily be left with the impression that there really are no difficult intellectual problems in university administration. In fact, there are some very difficult intellectual problems, and the future of British higher education depends on the way they are solved. Here (for Sir Ronald Pellew's benefit) are three of them. The new University will need a constitution. Will the constitution affirm that the University is a self-governing society whose members, the academic and senior administrative staff, are not employees but co-partners ? Or will it follow the example of Keele and Sussex, the constitutions of which leave everyone guessing whether a university teacher is a member of a society or an employee in a hierarchy ? Secondly, the new University will need to determine the standard and content of its degree. Everyone will assume that the standard must be identical, and the content only slightly at variance, with that in all other British universities, guaranteed by an academic advisory committee and enforced by an annual visitation of external examiners, which would mean that any really revolutionary ideas about the pattern of degrees (such as are to be found in Moscow or Chicago) would be withered by the arid scorching wind of academic public opinion. Thirdly, everyone will assume that the new University will teach for about 22 weeks out of 52, with examinations for another 4 weeks, thus perpetuating the belief that students read and reflect in the vacations, whereas in fact they pick peas or work in cafés; and that professors do research and re-write lectures, whereas some of them paint the bathroom and earn extra money by writing broadcasts. Will Sir Ronald think about these, and a dozen other equally important problems ? Or will he accept current practice on these big matters, and confine his innovations to trivialities ? "BRUCE TRUSCOT, JUN."

* *Science in Government and Industry*: a Policy Statement by the Association of Scientific Workers. Pp. 8. (London: Association of Scientific Workers, 1962.) 1*s*.

A MODERN DIALOGUE

A Threefold Cord

Philosophy, Science, Religion. A Discussion between Viscount Samuel and Professor Herbert Dingle. Pp. 280. (London: George Allen and Unwin, Ltd., 1961.) 25*s*. net.

THIS book is an extended dialogue in which Lord Samuel and Prof. H. Dingle try to elucidate and to reconcile the points of view of a philosopher and a scientist. It begins appropriately with a chapter entitled "View-Points". Then it examines topics of special interest in three chapters on "Energy and the Ether", "Science and Mathematics" and "Life and Mind"; and it ends with a chapter of "Retrospect and Prospect", in which the authors, having re-stated their differences, hope for a new harmony in religion.

All this ought to make a fascinating progression, particularly in the hands of two men who write so clearly and so well as Lord Samuel and Prof. Dingle. Alas, the book disappoints our expectation. There is no progression; each author virtually ignores the arguments of the other; and their exchanges become a series of repetitions which throws no new light on the views of either. Perhaps the form of the dialogue, which worked so well between Socrates and his young friends, is not suited to two protagonists of equal intellectual standing. In this book it has merely encouraged the authors to digress, and to ride away from the debate on hobby-horses of their own.

But there is a deeper reason for the inconclusiveness of the book; it springs from the narrow and sectarian way in which the authors present their two disciplines. If common ground is to be found between philosophy and science, then it must surely be looked for, not in one philosophy and not in one interpretation of science, but in the basic objectives of the two studies. The writer who wants to show that philosophy has something helpful to say to scientists must be willing to speak for what is fundamental to all philosophy as a mode of inquiry, and which makes it different from other modes. He must show what philosophy is at and what it is about—above all, why the questions which philosophers ask are not foolish. Similarly, the spokesman for science must express the aims and demonstrate the methods which are shared by all scientists. He must show how the theories of science are related to the findings in the laboratory, and why; at bottom, he must explain to the philosopher why the precise questions which scientists ask are thought by them to be interesting.

The authors of this book have attempted nothing so ambitious as this. Lord Samuel does not try to speak for philosophy as such, or to present it as a method with its own unity. Instead, he states and re-states his personal philosophy, which is a kind of common-sense realism; when he refers to other philosophers, it is almost always critically. Equally, Prof. Dingle does not try to give a reasoned exposition of the principles which underlie all the sciences (including the biological sciences). Instead, he confines himself to explaining, patiently and often, his own rigid view of science as an operational technique. When he describes the outlooks of other scientists, he leaves no doubt that he thinks them illogical and even bigoted, and Lord Samuel joins him in these criticisms. Indeed, the one ground on which the authors are usually united is their distaste for the views of others.

It is not to be wondered at, then, that Lord Samuel and Prof. Dingle find little to agree on at the end of the book. Common-sense realism on one hand, and scientific operationalism on the other, have not much in common. But even if they had more, it would give no help to the philosopher in general or to the scientist in general. Most scientists think that philosophy is an artificial study, and many philosophers think that science is a pedestrian study. This book does nothing to correct their prejudices.

J. BRONOWSKI

A TEXT-BOOK OF PHYSICAL ANTHROPOLOGY

Manual of Physical Anthropology

By Prof. Juan Comas. Revised and enlarged English edition. Pp. xxi + 775. (Springfield, Ill.: Charles C. Thomas; Oxford: Blackwell Scientific Publications, 1960.) 140*s*.

THIS manual first appeared in Spanish in 1957 and arose, as Prof. Comas states in his prologue, partly as a result of his teaching experience and partly in answer to the need for a suitable text-book in the Latin American world. It now has appeared as a revised and enlarged English translation with a preface by Prof. W. M. Krogman.

A brief outline of the contents will indicate the scope of the work. It commences with the history and objectives of the subject, followed by the elements of genetics including a section on race mixture and racism. After a general account of growth with an evaluation of measurements and indexes, there are sections on descriptive observations of the living, serology, somatometry, biotypology, osteology and palæoanthropology. Contemporary racial classifications are compared and the principal living peoples described. The final chapter is on the application and teaching of physical anthropology. In the appendixes the international agreements on anthropometry of Monaco and Geneva, and the Unesco statement on race are reproduced as well as several blanks for recording data. The bibliography deals with the principal works under subject headings and in addition there is a list of periodicals. There are separate indexes for authors and subjects, and throughout the book sources are given by means of footnotes on the relevant pages.

The author follows the classical tradition of physical anthropology and, in so far as he does so, he strikes a good balance between the different sections. However, one wonders whether this concept is not too narrow. The whole field of physical anthropology has altered so radically that to-day there is a much greater emphasis on genetics, biochemistry, physiology, pathology, statistics, experimental morphology and the study of behaviour and of populations and, unfortunately, this change is not revealed in the manual. It is a great pity, for the book stimulates thought and a healthy critical outlook in what it covers. The time has probably come when single authorship has become hazardous in attempting to encompass the whole subject in a sizeable volume. One makes this criticism with all due deference to the author, who has undoubtedly marshalled quite an array of material.

On the positive side one has to welcome the number of French, Spanish, Italian and South American references that are included and which so often have either been omitted or are even unknown to English-speaking people. The applied side of the book is the most valuable part. Thus, the measurements frequently used in studies of growth, the helpful introduction to somatology, the sections on somatometry and osteometry, and the evaluation of various methods used in the estimation of stature and sexual differentiation, as well as the practical advice on collecting, restoring and preserving material are excellent. The part on race mixture and racism is well balanced. The section on palæoanthropology is sound, the different schools of thought are fairly presented, and the final chapter on the application and teaching of physical anthropology is important and useful. The many tables and figures are clear and instructive.

Apart from the overall criticisms made, there are certain points one has to raise. Thus, the growth section does not mention the work of Brozek or Tanner and the work of the latter should also have been considered in the chapter dealing with biotypology. The photoelectric method for the evaluation of skin colour is insufficiently emphasized; this technique surely gives the most precise results and therefore should have been dealt with more fully than the more historic methods. The work of Barnicot on pigmentation, and the association of sickle-cell disease and malaria are not mentioned, and thalassæmia, the hæmoglobins and haptaglobins are omitted. When considering brachycephalization some account might well have been given of recent hypotheses instead of mere references. In the discussion on dating fossil material, the nitrogen and potassium–argon methods are not mentioned. More space could have been devoted to the important subject of population biology. Nor has population genetics been touched on. The bibliographical list of principal works should have included that of Li on population genetics and of Rensch on evolution. In the periodical section, reference ought to have been made to two important abstracting journals, *Excerpta Medica* (Section I) and *Biological Abstracts*, and to certain journals on genetics. A few authors, though referred to in the text and in the author-index, are not cited in the relevant footnotes where the references are usually given in this book, for example, Zook (p. 204) and Geissler (p. 221).

The production is of the usual high standard one has come to expect from this publisher. But the price is prohibitive.

F. P. LISOWSKI

DEVELOPMENTAL BIOLOGY AND INFORMATION THEORY

Oogenesis

The Storage of Developmental Information. By Prof. Chr. P. Raven. (International Series of Monographs on Pure and Applied Biology. Division: Zoology, Vol. 10.) Pp. viii+274. (London and New York: Pergamon Press, 1961.) 50s. net.

THIS book, which deals with some of the major problems in developmental biology, will present many biologists with their first introduction to the concept of information theory. Derived from communication engineering, information theory might seem very remote from the subject of oogenesis, but Prof. Raven, using a minimum of technical terms, quickly and convincingly explains its application. On this basis, the author examines the intricate relationship between oogenesis and the storage of developmental information in the fertilized egg at the beginning of its development, and how this information is transmitted from one generation to the next through the egg cell.

The book is divided into 10 chapters, which cover: embryonic development as a communication problem; the formation of egg cells; the egg nucleus during oogenesis; the cytoplasm and its inclusions; the relationship between the egg cell and the auxiliary cells; metabolism of the oocyte; the cortex; polarity and symmetry; the storage of developmental information, and information theory and biology. Much of the book is given to a detailed account of the mechanisms by which substances are transferred from the maternal tissues to the oocyte, and the transformations which they undergo during the growth of the latter.

Throughout the animal kingdom, there is great diversity in the structure and function of the egg cell. By selecting examples from a wide variety of species, both vertebrate and invertebrate, attention is directed to the comparative nature of the problem. This approach is particularly stimulating.

In attempting to derive estimates of the amount of developmental information carried by the nuclear genes, the cytoplasm and the cortex of the egg, it is agreed that the figures can only be crude approximations. The picture is further complicated by the existence of unknown quantities of redundant information. However, as a starting point, these estimates should provide a useful basis for further thought.

Although many controversial points are raised and some debatable assumptions have had to be made, the discussion is well balanced; where information (in the ordinary sense) is lacking, due allowance is made. By pointing out, in the appropriate places, that our knowledge is fragmentary, for example, little is known about the egg cortex, subjects for further research are suggested.

When refuting Elsasser's statement (p. 215) "that the great majority of germ cells produced by a healthy organism are viable", the author is possibly equally open to criticism in concluding "that in most animals a completely normal germ cell is rather an exception than the rule". One further minor criticism concerns the misleading impression given on p. 30 where it is stated that in mammals the egg is extruded into the abdominal cavity. Mention of the oviduct would have eliminated the ambiguity. To make these two points is in no way meant to detract from the general excellence of the discussion.

The book is amply illustrated with 44 text-figures and 4 plates, including 5 electron micrographs, which show the value of electron microscopy in the analysis of the fine structure of the egg. There is a good bibliography, containing nearly 400 references. Author, taxonomic and subject indexes complete the work.

Written in a clear style, this informative and stimulating book will appeal especially to those interested in embryology, genetics and theoretical biology; it is confidently recommended.

C. E. Adams

BIRDS OF THE AFRICAN CONTINENT

Birds of the Southern Third of Africa

By C. W. Mackworth-Praed and Captain C. H. B. Grant. (African Handbook of Birds, Series 2, Vol. 1.) Pp. xxiv + 688 + 38 plates. (London: Longmans Green and Co., Ltd., 1962.) 50*s.* net.

The two volumes (now in their second edition) of the first series of the *African Handbook* covered eastern and north-eastern Africa, from the Sahara to the Zambesi; the second series covers the continent south of the Congo–Zambesi divide, and on the western side includes most of Angola. This first volume deals with all the non-passerine birds and the first four passerine families. Captain Grant died in 1958; but the greater part of the work had been completed by then.

Their basic taxonomic studies had been published in detail by the authors in scientific journals over many years; the essential facts are now presented in didactic and summary form. Distinguishing characters and distribution are particularly stressed. The information on habits is often extremely brief, as in many instances little is available; the authors' avowed intention is to provide a sound basis of identification for the further field observations for which there remains so much scope. For that purpose this volume, with its companion to follow, should prove most useful and convenient. In addition to coloured plates by various artists, and some photographs, marginal drawings and little distribution maps are again a welcome feature.

In general, we have a picture of the bird-life of a large area, partly tropical and largely warm temperate in climate, presenting a considerable range of environments. There are mountains rising to 6,000 ft. or more, many important rivers, and a long coastline; there is not much dense forest and only one 'true' desert; woodland of different kinds, grassland, and semi-desert make up the greater part. Some habitats have been altered or destroyed by man, deforestation often being followed by erosion; elsewhere shade and water have been created where they did not exist before. This is a 'wintering' ground (in the southern summer) for many migrants from Europe and Asia; it is inhabited during part of the year by species that spend the other part in equatorial Africa; and it is the permanent home of many that are either sedentary or migrate only within the area. The breadth of the representation of different groups may be judged from the fact that the first two species to come under notice are the ostrich and the only native penguin.

Landsborough Thomson

ASPECTS OF SOLID-STATE PHYSICS

Solid State Physics

Advances in Research and Applications, Vol. 11. Edited by Frederick Seitz and David Turnbull. Pp. xvi + 438. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1960.) 12.50 dollars; 89*s.* 6*d.*

A further volume of *Solid State Physics* provides us with another five authoritative review articles on various aspects of the subject: two on specially important materials (grey tin and cadmium sulphide) and three on techniques which have wide application (high pressures, piezo-resistance effects in semiconductors and cyclotron resonance).

The article on the semiconducting properties of grey tin by G. A. Busch and R. Kern is like an ingenious puzzle which must be both set and solved by the players. The game is to assign the characteristic parameters—energy gap, effective mass, etc.—so as to fit best the experimental results. What makes the game especially piquant here is the paucity of the experimental results. R. H. Bube's essay on ionization energies associated with imperfections in CdS-type materials displays (in contrast) an indigestible feast of experimental results.

Perhaps the most appealing article of the collection is C. A. Swenson's account of high-pressure physics since 1945. Like low-temperature physics, high-pressure physics is a dying subject—not indeed because it is no longer being practised, but because it is being so widely practised that the element of 'craft' has passed over to technology. This article may thus prove to be a memorable 'obituary' which will be used and enjoyed for many years.

An instructive lesson on the power of resonance techniques can be obtained by comparing the article by B. Lax and J. G. Mavroides on cyclotron resonance with that of R. W. Keyes on piezo-resistance in semiconductors. The latter, 'classical' technique yields at the best vague information about band structure. The former, however, has given an astonishing amount of new knowledge in a short space of time: the authors have no difficulty in showing that it is the most important and promising technique available.

This volume of *Solid State Physics* includes a cumulative subject-index of Volumes 1–10.

R. O. Davies

Diagnostic Methods in Veterinary Medicine

By Prof. Geo. F. Boddie. With a chapter on Diagnosis of Poultry Diseases by Dr. J. G. Campbell. Fifth edition. Pp. ix+420. (Edinburgh and London: Oliver and Boyd, Ltd., 1962.) 30*s*. net.

THIS is a good book written by a clinician for clinicians. The arrangement is consequently according to the demands of the man observing a case. The general clinical everyday methods of observation and examination are given most of the space in the text, and special and elaborate systems of diagnosis are, in general, relegated to special chapters. Nine of the twenty-one chapters are concerned with body systems, and the amount of clinical detail covered is extraordinarily complete.

Specific infective processes are less completely covered and many that might lead the veterinarian to consult the book, for example, melioidosis or coccidioidomycosis, are outside its scope.

There is much more in the book than is indicated in the contents pages. Tables that are given in sequence in certain chapters might be numbered serially throughout the volume and listed as such on a preliminary page. With such a mass of essential information some greater breakdown showing where special items are to be found would help a reader.

For the practitioner on the farm or in the town the book is an essential source-book to be consulted at every contingency. The publishers' share in the work is up to the standard to be expected of them.

W. A. Pool

Synovial Joints

Their Structure and Mechanics. By C. H. Barnett, Prof. D. V. Davies and Prof. M. A. MacConaill. Pp. xi+304. (London: Longmans Green and Co., Ltd., 1961.) 50*s*. net.

THIS book sets out, at not too great a length, the modern views on most aspects of synovial joints. It is divided into four sections, the first dealing with the structure and composition of the various components of joints, and the second with such physiological topics as their nutrition, repair and development. The third section is an entirely non-mathematical treatment of the mechanics of joint movement (though adequate in its way, this section would have been improved by the addition of an extra chapter setting out some of the ideas in a rigid mathematical form). Various functional aspects are discussed in a final, shorter section.

The medically qualified reader, for whom the book is primarily intended, will find it most useful. The non-medical biologist, provided he can accept the extensive use of anatomical terms, should find that there are several chapters to interest him. The anatomical emphasis is very strong, reflecting the fact that all three authors are in anatomy departments. Other disciplines have not been ignored, but some of the biochemical asides could be misleading to the uninitiated. Although the individual authorship of certain passages is here and there detectable, the three authors have achieved a commendable degree of uniformity of style. The overall balance is good, though a few hobby horses have been ridden rather hard. The book is well documented, with more than 400 references, which appear to have been well chosen. The bibliography has been made all the more useful by the inclusion of an author index.

P. R. Lewis

Progress in Operations Research

Vol. 1. Edited by Russell L. Ackoff. (Publications in Operations Research, No. 5.) Pp. xii+505. (New York and London: John Wiley and Sons, Inc., 1961.) 92*s*.

THIS book, the first of a set of review volumes dealing with research methods, is number five in the series *Publications in Operations Research*. The set is to be a basic reference work, and, if this first volume is a guide, will undoubtedly be just that: a reference rather than an exposition. Apart from chapters of a general character, on subjects such as "The Meaning, Scope, and Methods of Operations Research", there are chapters dealing with subjects carrying specific mathematical apparatus, such as inventory theory, programming, Markov and queueing processes, sequencing theory and replacement theory. But these chapters, while they will be of value from the bibliographical point of view, are intensely unsatisfying. The reader is likely to feel insecure in that he will have been taken on a quick tour of inspection of some field, without being able to linger on detail at any point. The only exception to this seems to be the chapter by Prof. Morse on the dynamics of operational systems, which is excellent in that it combines a fine, expository power with some real mathematical technique.

For the postgraduate student contemplating entry into the field of operations research, the present book will be valuable in that it gives a quick bird's-eye view of practically all the methods so far used. There is also an ample bibliography at the end of each chapter to guide future reading, and the book, on the whole, achieves its aim of making the content of recent work in operations research readily available.

L. S. Goddard

Transformers and Generators for Power Systems

Their Behaviour, Capabilities and Rating. By R. Langlois-Berthelot. Translated and revised in collaboration with Lieut.-Colonel H. M. Clarke. Pp. 541. (London: Macdonald and Co. (Publishers), Ltd., 1960.) 65*s*. net.

THE writer is known, not only as a distinguished French engineer but also as the author of a series of four text-books which have been in use by French engineers and in the French colleges for several years. The present volume, together with the earlier work entitled *Electro-magnetic Machines*, covers the range of the four French books. They are, however, not exact translations but have been adapted to British needs with the help of Lieut.-Col. H. M. Clarke. As would be expected, the book takes full account of modern developments and, moreover, has a very valuable bibliography.

The book is of particular value to engineers interested in transformers and synchronous machines in relation to their application rather than to questions of detailed design. All the important practical operating problems are discussed, ranging from insulation and heating to steady and transient performance. It is of considerable interest to advanced students in the electrical power field, but in Britain it is of less value for undergraduate students because of the growing tendency in college courses to concentrate more on physical fundamentals than on the techniques used for exploiting them. Very little time is devoted nowadays in an undergraduate course to the subjects covered by this 540-page book.

B. Adkins

NEW SCALE OF NUCLIDIC MASSES AND ATOMIC WEIGHTS

By Dr. EDWARD WICHERS
Associate Director, National Bureau of Standards, Washington, D.C.

IF physicists and chemists accept the recommendation of their principal international bodies, the International Union of Pure and Applied Physics and the International Union of Pure and Applied Chemistry, they once again will be using a common scale for expressing the relative masses of atomic particles. For about thirty years two scales have been in use, both based on the integral number 16. On one scale, commonly called the chemical scale, this number was used as the relative atomic weight of the element oxygen. On the other, the physical scale, the same number was used as the atomic or nuclidic mass of the principal isotope of oxygen. If expressed on the physical scale the atomic weight of the element oxygen would be approximately 16·004 instead of 16. The new, unified, scale has as its denominator the integral number 12 as the relative mass of the atom of the principal isotope of carbon, ^{12}C. On this scale the atomic weight of oxygen becomes 15·9994. For those whose interest may go beyond this brief statement of a completed interdisciplinary agreement the following discussion will describe the situation that led to the existence of the two scales and the considerations that have now led to their replacement by the new unified scale.

An inescapable consequence of the atomic theory of matter, as first clearly enunciated by Dalton, is that every atomic particle of a given species of matter must be identical in all respects with all other particles of the same species and must differ characteristically from the particles of all other species. Thus, the masses of atoms were early regarded as natural constants of fundamental importance. For a long time the absolute magnitude of atomic masses could only be estimated; but most purposes of physical science were served by knowing the relative masses of the different kinds of atoms. This knowledge, combined with the discovery of the laws of simple and multiple proportions, made it possible for chemistry to evolve from a merely descriptive to a quantitative science.

A very large part of chemical research during the nineteenth century was concerned with the discovery of what were then regarded as the fundamental species of matter—the chemical elements—and with the determination of their relative atomic masses. At first the only available way to determine atomic masses was to measure the weights of the various elements that were equivalent to one another in selected chemical reactions or that combined to form simple molecules. Thus, the term 'atomic weight' came to be used to express the more fundamental concept of relative atomic mass. The numerical expressions of these two properties of an atom are normally identical, since relative atomic weights are always measured in a common gravitational field. To-day, the two terms are often used interchangeably, with some confusion of meaning that could be avoided if 'atomic mass' were reserved for the species of matter now known as nuclides and 'atomic weight' were used only in its traditional connotation, that is, for elements.

The precision and the accuracy of the determination of atomic weights increased steadily during the latter part of the nineteenth century. They reached their height in the early part of the twentieth century in the work of T. W. Richards and G. P. Baxter and their associates at Harvard University, and of O. Honigschmid and his many collaborators at Munich. Paradoxically, the remarkable precision of the measured atomic weight of lead from different sources proved beyond question that the atomic weight of an element is not necessarily constant. The consequence of this discovery was the realization that the substances known as elements are not necessarily composed of identical atoms, but that some elements may be composed of a mixture of atoms which are essentially identical in chemical properties but not identical in mass. Such species of matter were given the name 'isotopes'.

To-day, we know that most of the ninety-odd elements occurring in Nature exist as mixtures of isotopes. There are about 300 naturally occurring isotopes, and several hundred additional isotopes can be prepared artificially; but the concept that the mass of an atomic particle is constant is now more firmly established than it was before isotopes were discovered. This is so both because of advances in the knowledge of the fundamental nature of matter and because modern methods make possible much more exact measurements of nuclidic masses. However, it should be noted that although the masses of individual nuclides that constitute an element can be measured very accurately, their abundances in an element cannot be determined, as yet, with equal accuracy.

The chemist is no longer unaware of the existence of isotopes or of the fact that the chemical properties of isotopic species are not strictly identical. Nevertheless, in most of his work he deals with the chemical elements as they exist in Nature, whether as a single nuclide or as a complex mixture of isotopes. Therefore, when he is concerned about the proportions in which elements react with one another he needs to know the average mass of the mixture of nuclidic species which constitute the element. This is the quantity that has been called the atomic weight of the element, and the term is still useful provided certain limitations are attached, particularly the limitation that the element be in its natural condition, unmodified in its isotopic composition by human intervention or as the result of the naturally occurring phenomena of radioactivity. In contrast, the atomic physicist is usually concerned with individual nuclidic species—the differences in their nuclear characteristics and the nuclear, as opposed to chemical, changes they undergo.

These divergent interests of the chemist and the physicist have been reflected in the use of different bases of reference for denominating nuclidic masses and atomic weights. Early in this century chemists differed in their ideas about the best way to express atomic weights. Some believed it was best to base the scale of atomic weights on unity as the atomic weight of hydrogen, the lightest element. Prout's hypothesis, that all the elements are composed of hydrogen and thus that their atomic weights should be multiples of the atomic weight of hydrogen, undoubtedly had a strong influence on this choice of scale. However, oxygen was more useful than hydrogen as an operational reference species, because it forms stable and manageable compounds with more elements. This consideration led to an international agreement, early in the twentieth century, to base the scale of atomic weights on oxygen as the reference species, with an assigned integral atomic weight of 16. There was a transition period during which text and reference books continued to publish two tables of atomic weights, one based on H = 1 and the other on O = 16. The oxygen scale had been firmly established when Aston, about 1920, built the first mass spectrograph and began to measure atomic masses.

The later discovery that natural oxygen contains small proportions of isotopes of nominal masses 17 and 18 made it evident that Aston's mass ratios were not based on natural oxygen, as he had supposed, but on the dominant isotope of oxygen. However, Aston continued to use the integral number 16 as the relative mass of this isotope and thereby established a new scale of nuclidic masses, which came to be known as the physical scale. This was done with the approval of the International Commission on Atomic Weights, of which Aston himself was a member. At that time it was scarcely possible to foresee the ultimate effects of the decision. The concentrations of ^{17}O and ^{18}O in natural oxygen were not known and would not be determined accurately for some years. Furthermore, it does not appear to have been foreseen that mass spectroscopy would provide a valuable technique for the determination of atomic weights. Thus, when refinements of the technique proved it to be a reliable method for determining atomic weights, it was necessary always to convert data measured and reported on the 'physical' scale to the established scale by a factor based on the isotopic composition of natural oxygen. This composition proved to vary slightly with the source of the oxygen; but from 1940 the International Commission stabilized the conversion factor at 1·000275 and thus established a conventional, although never formally defined, relation between the physical scale of atomic (nuclidic) masses and the chemical scale of atomic weights.

Scientists were thus confronted with a situation similar to that existing when the hydrogen and oxygen scales were in simultaneous use. However, the difficulties were now much more serious because, in the meantime, there had been accumulated an enormous volume of data on physico-chemical properties of systems the composition of which was expressed in gram-equivalents or gram moles, on the chemical scale. Some molar quantities, such as Avogadro's number, the Faraday constant, and the universal gas constant were expressed sometimes on one scale and sometimes on the other, without identifying the scale. Not infrequently thermodynamic quantities began to appear which were derived partly from data on one scale and partly from data on the other, without stating the distinction. Some of the data were accurate enough so that the difference between the two scales could not be neglected without impairing the usefulness of the derived quantities.

In view of these circumstances and the prospect that confusion would increase with further improvement in the accuracy of physico-chemical measurements, the International Commission on Atomic Weights began in 1955 to study the possibility of unifying the scales or of adopting a new scale. Scales based on ^{1}H = 1 and ^{4}H = 4 had been suggested earlier, but neither of these appeared satisfactory. The simplest procedure would have been to abandon either the chemical or the physical scale in favour of the other but neither alternative was acceptable. Chemists recognized the logical superiority of a scale based on a reference species the atomic weight of which was invariant but were reluctant to face the problems resulting from introducing a systematic change of nearly 3 parts in 10,000 into many recorded molar data. From this point of view a new scale, to be acceptable, should not result in more than very small numerical changes in quantities based on the existing chemical scale. Physicists, on the other hand, were understandably opposed to exchanging a single nuclide for a mixture of nuclides as a reference species, even if the composition of the mixture were to be fixed by definition. Furthermore, they considered it essential to use an integral number as the assigned relative mass of the reference nuclide and thus to provide a simple basis for the definition of the 'absolute mass unit'. For example, the absolute mass unit based on the ^{16}O scale is 1/16 of the mass, expressed in grams, of an atom of ^{16}O. By preference the integral number taken as the assigned relative atomic mass of the reference nuclide should be identical with its 'mass number'. (The 'mass number' of a nuclide is the sum of the nucleons, protons and neutrons, contained in its nucleus.) It is desirable that the mass number be identical (by definition) with the atomic mass of the reference nuclide, even though no other nuclide will have an exact integer for its atomic mass.

If the chemist's desire to avoid more than a minimal change in the values for atomic weights and the quantities based on atomic weights was to be satisfied, the choice of a new reference species was limited to a small number of nuclides. Use of the following nuclides would result in the indicated changes from values expressed on the chemical scale: ^{12}C, −43 parts per million; ^{15}N, −30 p.p.m.; ^{17}O, +9 p.p.m.; ^{18}O, +4 p.p.m.; ^{19}F, +41 p.p.m. By contrast, the adoption of ^{16}O (the existing physical scale) would cause a change of −275 p.p.m. Of the foregoing, only ^{12}C was fully acceptable to physicists as a possible replacement for ^{16}O. As the principal isotope of carbon this nuclide has long served as an operational reference species in mass spectroscopy. In the form of singly, doubly, or triply charged hydrocarbon ions ^{12}C is capable of supplying an almost unlimited number of masses for the doublet technique of determining mass differences by mass spectroscopy. ^{12}C appeared also to be satisfactory as a basis of reference in the derivation of nuclidic masses from 'Q values'—the net energy changes involved in nuclear reactions. However, the change from ^{16}O to ^{12}C as the reference species would result in changes of about 300 parts per million in values for nuclidic masses.

Various objections can be made to the other nuclides listed already. ^{15}N, ^{17}O and ^{18}O are minor isotopes not readily available for direct experimental

Table 1. INTERNATIONAL ATOMIC WEIGHTS—1961

comparisons. They were unacceptable to physicists for other reasons also. The element fluorine, which is composed solely of ^{19}F, was somewhat attractive to chemists because of its possible use as an operational standard for chemical determinations of atomic weights. It would not be suitable, however, as an operational standard for mass spectroscopy. Thus, the only possible basis for achieving a unified scale appeared to rest on the acceptance of ^{12}C as the reference species. Fortunately, this choice proved to be acceptable to both chemists and physicists.

In 1959 the International Commission on Atomic Weights recommended the adoption of ^{12}C as the reference species, with assigned relative mass of 12, provided physicists would also accept it in replacement of ^{16}O. During the ensuing year the proposal was thoroughly examined in Europe and North America. Under the persuasive leadership of Prof. J. Mattauch, the proposal generally came to be viewed with favour among physicists, and in September 1960 it was formally adopted by the General Conference of the International Union of Pure and Applied Physics. In 1961 the International Union of of Pure and Applied Chemistry confirmed the recommendation that had been made provisionally in 1959.

The adoption of the new unified scale of nuclidic masses and atomic weights by the two international scientific bodies most directly concerned with a matter of this kind does not necessarily ensure that the scale will be universally used. Scientists are not obliged to adopt standards or practices recommended by scientific organizations, whether national or international. However, chemists have long looked to the International Union of Chemistry and its Commission on Atomic Weights for authoritative judgments on matters relating to atomic weights. They are therefore very likely to accept without delay the "1961 Table of Atomic Weights", which is based on the new scale. Physicists have not had until recently a similar body to recommend 'best values' for nuclidic masses, but a Commission on Nuclidic Masses was established by the Union of Physics in 1960. Concurrently, a "Table of Nuclidic Masses" has been published[1]. This "Table" gives the results of a thorough analysis of all available sources of information. Data are tabulated on the basis of both the ^{12}C and ^{16}O scales, thus permitting ready comparisons. It is to be hoped that henceforth new physical data will be published in terms of the ^{12}C scale and preferably on this basis exclusively. It would be unfortunate indeed if the new unified scale should fail to displace, within a reasonable time, both of the scales which have been used heretofore.

In connexion with its recommendation to adopt the ^{12}C scale, the Commission on Atomic Weights sponsored a thorough and complete review of the experimental evidence from which atomic weights can be derived. The "1961 Table of Relative Atomic Weights" (Table 1) lists the recommended values for atomic weights that resulted from this review.

Those familiar with earlier "International Tables of Atomic Weights" will find this one different in a number of respects. There are changes in the values for many elements, resulting in part from the system-

---

* The atomic weight varies because of natural variations in the isotopic composition of the element. The observed ranges are boron, ±0·003; carbon, ±0·00005; hydrogen, ±0·00001; oxygen, ±0·0001, silicon, ±0·001; sulphur, ±0·003.

† The atomic weight is believed to have an experimental uncertainty of the following magnitude: bromine, ±0·002; chlorine, ±0·001; chromium, ±0·001; iron, ±0·003, silver, ±0·003. For other elements the last digit given is believed to be reliable to ±0·5.

Table 2. THE RADIOACTIVE ELEMENTS—1961

Atomic No.	Name	Symbol	Isotope	Half-life	Mode of disintegration
43	Technetium	Tc	97	$2·6\times10^6$ years	Electron capture
61	Promethium	Pm	147	2·6 years	β-
84	Polonium	Po	210	138 days	α
85	Astatine	At	210	8·3 hours	α
86	Radon	Rn	222	3·8 days	α
87	Francium	Fr	223	22 minutes	β-
88	Radium	Ra	226	1,622 years	α
89	Actinium	Ac	227	21 years	β-, α
90	Thorium	Th	232	$1·4\times10^{10}$ years	α
91	Protactinium	Pa	231	$3·4\times10^4$ years	α
92	Uranium	U	238	$4·5\times10^9$ years	α
93	Neptunium	Np	237	$2·1\times10^6$ years	α
94	Plutonium	Pu	242	$3·8\times10^5$ years	α
95	Americium	Am	243	$7·8\times10^3$ years	α
96	Curium	Cm	247	$>4\times10^7$ years	α
97	Berkelium	Bk	247	c. 10^4 years	α
98	Californium	Cf	249	360 years	α
99	Einsteinium	Es	254	c. 320 days	α
100	Fermium	Fm	253	3 days	α
101	Mendelevium	Md	256	c. 1·5 hours	Electron capture
102	Nobelium	No		c. 10 minutes	α

atic conversion to the new scale, and in part from recalculation of the experimental work from which atomic weights are derived. Many values are given to a higher degree of precision than before. For several elements the precision is sufficient to require stating the range over which the atomic weight varies because of natural variations in isotopic abundances.

It will be noted that atomic weights are not given for radioactive elements other than thorium and uranium. Because the others are likely to be of uncertain isotopic composition, due to the circumstances attending their separation from natural materials or their artificial production, the assignment to them of atomic weights is difficult and of little value. Instead, the radioactive elements are listed separately in Table 2, which indicates the half-lives and modes of disintegration of selected isotopes. The review on which the "1961 Table" is based is the first comprehensive review since 1925 and the third in the history of the International Commission, the first having been made in 1909. The complete report of the current review will be published later this year in *Pure and Applied Chemistry*, the official journal of the International Union of Pure and Applied Chemistry.

THE UNIVERSITY OF LONDON 1961 BEERENBERG EXPEDITION

By FRANK J. FITCH
Birkbeck College, University of London

THE 1961 University of London Beerenberg Expedition to North Jan Mayen was planned as a continuation of previous British expeditions to this remote Norwegian island in the Greenland Sea[1–11]. The principal objective of the Expedition was to make a geological study and map of the great oceanic basalt volcano, Beerenberg (71° 05′ N., 8° 10′ W.), which dominates the northern half of Jan Mayen. The situation of Beerenberg on the arctic extension of the seismically and volcanically active Mid-Atlantic Ridge makes it especially interesting to geologists and geophysicists. Combined with the geological mapping was to have been a complete glaciological survey of the whole Beerenberg icefield and glacier system. Detailed investigations of Sørbreen, the large southern glacier of Beerenberg, had been made on previous expeditions[12–16], and it was intended that these should be repeated and extended. Among other objectives were certain mountaineering projects around the summit crater of Beerenberg essential to the scientific programme, the making of various rock and plant collections, general observations on the flora and fauna and the production of a colour ciné film. The expedition was financially supported by NATO, the Department of Scientific and Industrial Research, the Royal Society, the Royal Geographical Society, the Mount Everest Foundation, the University of London and by numerous commercial firms. Assistance and encouragement of every kind was obtained from the Norwegians, both on the island and in Norway.

A ten-man advance party sailed from Inverness in a chartered Norwegian sealer, the 133-ton *Signalhorn* of Aalesund, on June 10, 1961. The members of this advance party were F. J. Fitch (leader and scientific director, Birkbeck College), P. Smith (deputy leader and glaciological team director, Imperial College of Science and Technology), T. R. W. Hawkins (geologist, H.M. Geological Survey), D. Thomas (climber, H.M. Geological Survey), B. Roberts (geologist, Birkbeck College), C. M. Smith (glaciologist, Imperial College), J. D. Booth (glaciologist, Imperial College), J. R. Fraser (glaciologist, Imperial College), J. F. Cole (photographer, General Post Office Research Station) and P. J. D. Guile (technician, Imperial College). The geological party was landed north of the Beerenberg on June 15. By June 24 stores depots had been laid down at various points around the coast of Nord Jan, a base camp erected at Krossbukta and advanced camps and depots established high on the mountain to the north and south. The scientific work was well under way. The glaciological team under Peter Smith had already re-surveyed the snout area of Sørbreen and inserted four lines of stakes across the glacier for flow and ablation measurements, while in the north the geological mapping was progressing rapidly.

The early success of the expedition was destroyed, however, by a tragic accident on June 25, in which five men lost their lives and the leader was rendered unfit for several weeks. Fitch, P. Smith, Booth, Cole, Fraser and C. M. Smith were travelling north along the coast, to join the geologists for a combined attack on the Beerenberg crater, when their motor-boat was capsized in a sudden mountain squall. The five men who died were killed by the intense cold of the water before they could reach the beach only 100 yards away. As a result of a sea-search carried out by the Norwegian frigate *Garm*, the body of C. M. Smith was recovered and brought to the United Kingdom. The body of J. F. Cole was discovered later by a member of the crew of *Signalhorn* and buried on Jan Mayen.

After a period of uncertainty, it was decided that every effort should be made to complete the scientific programme of the expedition, especially the projects begun by the young men whose lives had been lost. A second geological party, J. Banfield (deputy leader and geologist, Neville Cross College, Durham), Miss R. J. Conran (geologist and naturalist, British Museum (Natural History)), Miss B. B. Fox (geologist, Overseas Geological Surveys), J. D. Slade (geologist, Birkbeck College), C. H. Talbot (geologist, Imperial College) and A. W. Wells (geologist, Birkbeck College), relieved the first party on July 14, and Fitch returned with a second glaciological party, D. J. J. Kinsman (glaciologist and geologist, Imperial College), J. W. Sheard (glaciologist and botanist, Imperial College), D. C. Birch (climber, Ilkley) and D. Thomas (climber, H.M. Geological Survey) on August 7. Before the expedition left Jan Mayen much of the original programme was completed. Only the parts which would have involved dangerous climbing on the east coast and in the summit crater had to be abandoned. Beerenberg was climbed on August 14 by Kinsman and Birch, and *Signalhorn* returned the remaining members to Inverness on August 20. Before leaving the island a memorial plaque to the lost men was erected near the head of J. F. Cole's grave at Krossbukta.

Most of the geological mapping programme was completed. 1 : 10,000 field slips cover all but the summit crater rim, the highest interglacial ridges and a short interglacial section of the east coast between Willebreen and Austbukta. Reasonably accurate interpretation of the geology of the area not covered by the large-scale mapping is possible on the basis of reconnaissance observations and rock collecting, and with the aid of extensive ground and aerial photography. The upper part of the mountain is, in fact, a large single lava cone of a distinctive basalt type, sitting on the crest of the main basalt dome of the Beerenberg. Its extent, even where hidden by the icefield, is indicated by a very clearly defined change of slope. The 1 : 10,000 mapping was based on a provisional stratigraphy proposed by Fitch and Banfield in 1959[11]. In an area of recent volcanics such as Jan Mayen, stratigraphical division is most obviously made between rocks of successive eruption cycles. Where there is a petrographic difference between rocks of successive cycles, geological mapping of these divisions can proceed in the usual way, but when, as in Nord-Jan, the petrographic difference between rocks of successive cycles is often not obvious in the field, alternative mapping methods must be used. Fitch and Banfield found that geomorphological evidence, based on a study of the denudation chronology, could be used to supplement the more usual geological criteria, and their mapping technique was successfully adopted by the expedition. As mapping proceeded it was found possible to extend the original stratigraphy, and to erect a series of rock-stratigraphic units to supersede it (Table 1). The age of the submerged volcanic basement of Jan Mayen is unknown, but for a variety of reasons it seems reasonable to assume that it is Tertiary. The growth of the Beerenberg in Nord-Jan began in the Pleistocene. Its rocks can be seen to rest on the old basement in places, and fragments of the older volcanics appear in many of the recent explosion breccias. In its structure and development Beerenberg closely resembles the Hawaiian volcanoes. It straddles a major multiple rift zone that runs north-east–south-west, following the local trend of the Mid-Atlantic Ridge. A subsidiary rift zone radiating towards the south-east from the summit gives it the typical Hawaiian tribrachial structure. A system of minor radial fissures is recognizable in places, and towards the north-east, confluence of fissures suggests the closure of the main volcanic structure in that direction. The overall structural pattern, the prevalence of fissure eruptions, open volcanic rifts, extensive dykes and normal cross-faults, combined with what evidence there is of the submarine topography of the Norwegian and Greenland Seas, strongly supports the view of Heezen and Ewing[17] that Jan Mayen is a volcano built on the flanking mountains of a major sub-oceanic rift valley structure.

Table 1

	Rock-stratigraphic units · North Jan Mayen	
Jan Mayen volcanic series		Smithbreen formation
	Nordkapp volcanic group	Kokslетta formation Tromsøryggen formation
		Sentralkrateret formation
	Kapp Muyen volcanic group	Nordvestkapp formation Havhestberget formation Storfjellet formation Kapp Fishburn Tillite Krossbukta formation
	Hidden volcanic group	
	Submerged volcanic group	

An extensive tillite horizon, the Kapp Fishburn Tillite, is thought to represent the deposits of the last Pleistocene ice-cap to form on Jan Mayen, its disappearance being correlated with the retreat of the Scandinavian ice from the Fennoscandian moraines. If this correlation is correct, the major part of the present Beerenberg is built of the products of eruptions occurring over the last 12,000 years. Certain features of the Havhestberget Formation suggest eruption during a period of cold climate that might be referred to the Younger Dryas Maxima. The ankaramitic basalt dome was completed by Nordvestkapp Formation volcanism. The building of the Sentralkrateret summit cone on top of the earlier dome, an event comparable to the late alkali–basalt volcanism of, say, Mauna Kea in Hawaii, most probably occurred during the Post-Pleistocene 'climatic optimum'. Evidence for this conclusion is principally geomorphological, and includes the smaller size of the summit cirques of this time, and the history of development of major sea-cliffs, now preserved in a fossil state. More recent volcanism, included in the Tromsøryggen and Kokslетta formations, has been essentially fissure eruption, both explosive and effusive, from the fissures of the main north-east–south-west rift zone. Fossil cliffs and a raised beach platform were formed in the interval between these two eruption cycles: they represent the maximum advance of the Post-Pleistocene sea some 3,500–4,000 years ago.

The present ice-field and glacier system is almost entirely the product of the 'little ice age' of the past 350 years. The breaching of the Beerenberg crater rim and the formation of the great glacial valleys of the north coast occurred during this period. The moraines of the present glaciation and those of an earlier advance, probably that known elsewhere to have occurred between 0 and 500 B.C., rest unconformably on the volcanics of the Kokslетta formation. The extensive coastal platforms and lava fields of this formation are therefore probably between 2,500 and 3,500 years old. Although no important volcanism has occurred since the Kokslетta eruptions, minor activity has been reported, and there is no valid reason for supposing that eruptions will not occur again on Jan Mayen, as they have on Tristan da Cunha. Moraines of an earlier glacier advance are found on top of the Tromsøryggen volcanics. The fossil sea-cliffs, 3,500–4,000 years old, post-date these moraines, so they must represent an ice advance about 4,000 years ago, at the close of the Post-Pleistocene warmer period.

The late Peter Smith and a team of glaciologists from Imperial College recorded a present-day minor re-advance of Sørbreen in 1959, and it was in order to extend these observations that a full glaciological survey of the Beerenberg ice was planned for 1961. Although certain of the high-level projects had to be abandoned as a result of the loss of the first glaciological team, it was possible to complete detailed observations on Sørbreen and to make a general survey of the other glaciers and of the summit rime domes.

Re-determination of the snout position of Sørbreen revealed a further advance of 124 metres between 1959 and 1961, making a total re-advance of 271 m. since 1949. The glacier has now almost regained its 1938 position. Surface flow measurements at the 130-, 310- and 910-m. stake lines across Sørbreen, made after an interval of between six and seven weeks, produced values ranging from 4 to 40 cm./day, the highest values being recorded from the 900-m. line and the lowest from the snout region. Ablation figures ranged from 1 to 5 cm./day. Observations on the other glaciers clearly demonstrate that the re-advance of Sørbreen is not an isolated feature, and that the whole Beerenberg ice system is in an active state. Spectacular advances can be seen in numerous places, accompanied by thickening of snout areas and the development of large seracs in the lower parts of glaciers.

It is apparent from a comparison of the Jan Mayen evidence with the evidence from other North Atlantic areas that the present Beerenberg ice-field expanded rapidly some 350 years ago. The main glaciers radiating from the mountain made a series of advances culminating about 1750, when the largest group of modern lateral and terminal moraines were produced. Since that time the glaciers have been in oscillatory retreat, each intervening re-advance reaching less far than its predecessor. Re-advances are thought to have occurred in 1810–20, 1850–70 and 1915–20, each producing its own distinctive moraines. The present-day re-advance began around 1954, and is probably near to its climax. Analysis of the climatic data for Jan Mayen and the surrounding areas reveals a remarkable correlation between glacier fluctuations and the weather patterns in the North Atlantic. There is nothing in the evidence from Jan Mayen to suggest that the current advance, or the present lowering of world temperatures, is more than a temporary regression in the course of the climatic amelioration that has been noticeable since the turn of the century. It seems likely that this long-term amelioration will continue until the climate of the North Atlantic region recovers its milder, pre-1600 A.D. character.

Extensive rock collections were made by the expedition for future petrographic and petrochemical investigation. Specimens were collected by a new technique for palæomagnetic study. A collection of 250 lichens was made for the British Museum (Natural History). Considerable photography was undertaken by the expedition. This included a colour ciné film and scientific record photography in black-and-white and colour. A novel camera-head, designed by Peter Smith, and constructed by P. J. D. Guile, made panoramic record photography possible in locations where only an ice-axe was available for support. It was thoroughly tested in the field and proved very satisfactory and useful. Although certain of the more adventurous parts of the mountaineering project had to be abandoned, such as the plan to enter and camp in the summit crater, considerable experience was gained during traverses of the larger glaciers and the ice-field, and on the climb of King Haakon VII Topp (7,470 ft.) made by Birch and Kinsman on August 14.

NATIONAL RESEARCH ORGANIZATIONS IN SOUTH-EAST ASIA

THE natural sciences programme of Unesco covers a wide range of activities, among the less-publicized of which are the science co-operation offices. These offices are facilitating co-operation in scientific work in the developing countries in a very practical way and are showing results which are out of proportion to the all-too-meagre resources allotted to them. A recent example of the important work of the South-East Asia Science Co-operation Office was the regional meeting of representatives of national research organizations called by that Office in December 1961 to discuss problems of the organization of scientific research in the area. It was held at Hong Kong in association with the Golden Jubilee Celebrations of the University of Hong Kong, and arose from a similar meeting held two years earlier at Bandung (*Nature*, 186, 859; 1960). Representatives of Australia, the Republic of China, Hong Kong, India, Indonesia, Japan, Korea, the Federation of Malaya, New Zealand, the Philippines, Singapore and Thailand were present. The meeting was inaugurated with an address by the Hon. Sir Sik Nin Chan, who stressed the importance of science and technology in assisting the industrial development of South-East Asia and the need for close collaboration if this was to be achieved. Dr. (now Sir) Lindsay Ride, vice-chancellor of the University of Hong Kong, was elected chairman of the meeting.

The general theme of the meeting, which had a rather wider aspect than that adopted at Bandung, was concerned with the development of national research policies in the South-East Asia region. The report, *Current Trends in Scientific Research* (the Auger Report), prepared by Unesco as a result of the resolution of the General Assembly of the United Nations on November 14, 1958, that a survey should be made of the main trends of inquiry in the field of natural sciences and the dissemination and application for peaceful ends of such scientific knowledge, was used as a background document.

The stage of scientific development, as represented by the national research organization, varied considerably in the countries of the area. Some already had large and effective national organizations which had made important contributions to their national development. Other research bodies were in a much earlier stage but had been successfully launched, while in other countries again national organizations had not gone far beyond the planning phase. Detailed accounts were presented of the progress that had been made in the two years which had elapsed since the Bandung meeting. These all reflected an increasing appreciation by Governments of the importance of scientific research, and the meeting considered some of the factors which were limiting expansion.

The great variation in the relative expenditures by different Governments was discussed. It was, of course, appreciated that the optimum effort would vary from country to country according to need, and also that the amount of money spent was not necessarily an accurate measure of the amount of research. It was felt, however, that it would be valuable to compare the expenditures of countries of the region as percentages of gross national products or of national budgets and the Unesco Office was asked to obtain and analyse figures for the countries of the area. (The meeting did not feel it would be proper for it to recommend a minimum figure for Government expenditure on research, though one delegate was prepared to go on record that this should be 1 per cent of the national budget.)

The question of extension—making use of research results obtained—should be a vital feature of a national research policy. Although in agricultural research the problems were now fairly generally understood, this was not the case in the industrial field. The translating of results of research to industrial practice was not an activity in which the research scientist was skilled, and various means of doing this (for example, the establishment of development authorities) were discussed. In many countries of the region, however, particularly those just beginning to build up industrial activity, the important need was to provide day-to-day assistance in solving smaller technical problems arising in the course of production—the application of existing basic knowledge and 'know-how'. In New Zealand this had been solved by the establishment of industrial development laboratories, and this principle was being followed by at least one other country in the area.

Although the meeting was primarily concerned with national research organization, it discussed the role of research in universities since the national organizations are dependent on the universities to provide them with trained personnel. It was vital for universities to undertake active research programmes so that students could be trained in methods of research. In some countries it was, of course, the policy to carry out much of the basic research in the universities or other institutes attached to them. In other countries the national research organization played a major part in assisting university research—this was particularly useful where the high cost of research facilities was a problem. In any event, the universities must occupy a position of high status in the national research scheme and there should be the closest collaboration between them and the national research organizations. Although it was emphasized that the responsibility for postgraduate training must be in the university system, it was felt that the recognition by the universities of outstanding scientists in the national research organizations as honorary university officers was most desirable.

Another problem which came under vigorous discussion was that of the promotion of science. In order to secure adequate support for scientific work it is essential that there should be an awareness throughout the community of its aims and objectives and the practical effect it can have in raising living standards and promoting national welfare. This was particularly important in countries in the South-East Asia region and it was agreed that two groups should be considered: Government and general public. If the ministerial head of the national research organization were a senior minister or his equivalent, science could make itself felt much more effectively. In India the fact that the Prime Minister himself was the minister concerned with the national research body had had a tremendous effect on its development. Every possible step should be taken by national research organizations to emphasize the value of investment in scientific research. Use should be made of all the mass media—the Press, films, radio, television, etc., for developing an awareness of science and its results. In particular, the Press reached a great proportion of the public, and provision of informative, well-written material was essential. Writing for this medium was a specialized task, and the number of competent scientific journalists available was very limited. The value of science museums in increasing public awareness of science was also stressed. It was important that young people should be interested at an early age not only to increase their understanding but also to interest them in the attractions of a career in science. The increasing demand for scientific manpower was making this more important, and in discussing this the meeting emphasized two important points. The first of these was the need in most countries for improving science education at the school-level. It would not be possible to attract the brightest children to a scientific career unless the subject was made interesting and exciting from the beginning. This required inspired teaching which would catch the imagination of young people and give them an idea of the excitement of the subject and its practical relevance in improving living standards and social conditions. In many countries the schoolteacher did not enjoy sufficient status to attract men and women of adequate intellectual calibre to the profession. The other point which was emphasized was the need for adequate pay and status for the scientist. In some countries of the area he did not enjoy the same standing as the administrative Civil servant and was obliged to undertake additional employment to ensure an adequate income. In these circumstances, the best minds would never be attracted to a research career, and it was desirable that countries should adopt a scientific policy which would materially improve the status of scientists.

The meeting emphasized the importance of scientific documentation centres, particularly in developing countries. Such centres had now been established, with the assistance of Unesco, in India, Pakistan and the Philippines, while one was being set up in Thailand and another planned in Indonesia. It was suggested that it would be impossible for each centre to build up a completely comprehensive service and the Unesco South-East Asia Science Co-operation Office at Djakarta was asked to examine the possibility of close liaison and co-ordination between the various centres. The Office was also asked to study the possibility of establishing regional scientific journals in the area. Although there was little difficulty in placing scientific papers in international journals in basic subjects like physics and chemistry, it was often hard to provide for publication of papers of specialized regional interest, for example, zoology, parasitology, botany, phytochemistry. Because of cost and limited output of papers, it was difficult for smaller countries to establish their own journals to cater for this type of material. Regional journals in such subjects would overcome the difficulties and ensure that the work could be properly recorded and made more readily available by libraries.

The meeting also examined a number of other aspects of co-operation, for example, technical assistance, regional collaboration in research and training, the exchange of scientists, regional scientific meetings, etc. The formal outcome of the meeting was a series of recommendations to the Director-General of Unesco that the South-East Science Co-operation Office should undertake a number of specific activities designed to strengthen the development of science in the countries of the region. The meeting also emphasized the importance of the work being carried out by the Office, which thoroughly justified the provision of additional funds to enable a substantial expansion of its activities.

The South-East Asia region embraces countries the stage of development of which varies over an extremely wide range, and the conference—more effective perhaps because of its small size and intimacy—should make a contribution towards achieving the purpose of the recommendations of the Auger Report: the better utilization of science for improving living standards. This is a goal which is common to the countries of the region, as is evidenced by the establishment or planning of national research organizations by all the Governments concerned. The desire for constructive international co-operation, demonstrated convincingly at this meeting as well as at Bandung, should have important practical results in helping the growth and work of these organizations, particularly in the less-developed countries. It should also have as a secondary, though no less important, consequence, a political dividend in the building up of international trust and confidence. This may be small in relation to the magnitude of international tensions, but it is nevertheless an important aspect of international scientific gatherings, particularly those like that described where there is a common interest in working together for constructive ends.

GUY B. GRESFORD

OBITUARIES

Prof. A. H. Compton

ARTHUR HOLLY COMPTON died on March 15 in Berkeley, California, as a result of cerebral hæmorrhage suffered two weeks earlier. He was sixty-nine.

He had retired last year as distinguished service professor of natural philosophy in Washington University (St. Louis), where he had served as chancellor from 1945 until 1953. He was planning to be active in retirement as professor-at-large between Washington University, the University of California (Berkeley) and the College of Wooster (Ohio), and had gone to Berkeley to deliver a lecture series on "Man, Science and Society".

Compton received his B.Sc. from the College of Wooster, where his father, Elias Compton, was professor of philosophy, and received his Ph.D. in 1916 at Princeton University. The next year he was an instructor at the University of Minnesota, and then was for two years a research engineer for the Westinghouse Lamp Company in Pittsburgh. The year 1919–20 was spent at Cambridge (England) as a National Research Fellow, after which he was appointed Wayman Crow professor and head of the Department of Physics at Washington University, where he remained until 1923. During 1923–45 he served as professor of physics and dean of physical sciences at the University of Chicago, until he returned to Washington University as chancellor in 1945. He was president of the American Physical Society in 1934, of the American Association of Scientific Workers in 1939–40 and of the American Association for the Advancement of Science in 1942. In 1927 he shared the Nobel Prize in physics with C. T. R. Wilson.

His career was marked by an extraordinary range of great accomplishments in physics, in higher education, in war-time scientific research, and in efforts to improve human and international relations.

While a student at Princeton he devised a beautiful demonstration of the Earth's rotation, which ought to be known to all teachers of physics. A toroidal glass tube is filled with water, and mounted so that it can be 'flipped' through 180° about a diameter as axis. Before flipping, the water is at rest relative to the tube, which is turning, relative to the fixed stars, in its own plane with the component of the Earth's rotational angular velocity normal to that plane. After flipping, the water drifts relative to the tube, at a rate proportional to that angular velocity component. By measuring the drifts produced by three successive flips about each of three mutually perpendicular axes, one finds the Earth's angular velocity as a vector; that is, one can infer which local direction is north, what is the observer's latitude, and what is the absolute value of the length of the day.

His first major discovery was the detailed measurement and interpretation of the wave-length change occurring when X-rays are scattered, especially by materials of low atomic number. This is now generally known as the Compton effect. He showed that the loosely bound electrons in the material scatter the X-rays in accordance with the principles of conservation of momentum and energy, as if they consist of a stream of photons, each having momentum of $h\nu/c$, as well as energy, $h\nu$. The energy aspect goes back to Planck and Einstein; but the Compton effect afforded the first clear demonstration that the X-ray photons also carry quantized amounts of momentum.

The next few years were marked by the development of coincidence methods by Compton and A. W. Simon in Chicago, and independently by W. Bothe and H. Geiger in Germany. These experiments showed that individual scattered X-ray photons and recoil electrons appear at the same instant in time, contrary to some views that were then being developed by Bohr, Kramers and Slater in an attempt to reconcile quantum views with the continuous waves of electromagnetic theory.

Compton also discovered the phenomenon of total reflexion of X-rays, and their complete polarization (with C. F. Hagenow), and first obtained (with R. L. Doan) X-ray spectra from ruled gratings. This latter work had an important consequence in leading to a distinct improvement in our knowledge of the electronic charge. By measuring an X-ray wave-length with a ruled grating of known grating space, and then using a crystal to diffract the same rays, one can determine the absolute value of the grating space of the crystal. Combining this with the measured crystal density, it is possible to obtain the Avogadro number, and combining this with the Faraday, the electronic charge is obtained. The outcome was that the Millikan oil drop value had to be revised from $4{\cdot}774$ to $4{\cdot}803 \times 10^{-10}$ c.g.s. E.S.U., it being finally recognized that systematic errors had been made in measuring the viscosity of air, a quantity which enters into the oil drop method.

From about 1930, Compton directed his attention mainly to the study of cosmic rays. In the next ten years he was in charge of a major programme involving a world-wide study of the geographic variations of their intensity. This resulted in full confirmation of some observations made in 1927 by J. Clay, indicating a latitude effect on the intensity. The world survey, in the service of which Compton made many long voyages, showed correlation of the intensity of cosmic rays with geomagnetic, rather than geographic, latitude. This opened the way for extensive subsequent studies of the interaction of the Earth's magnetic field with the incoming isotropic stream of primary charged particles.

In 1941 he was appointed chairman of the National Academy of Sciences Committee to Evaluate Use of Atomic Energy in War. In the autumn of 1941 this Committee worked with those responsible for studying this same problem in Great Britain, and also with the S-1 committee headed by Dr. L. J. Briggs, then director of the National Bureau of Standards. This led to recommendations to the United States Government for the setting up of a major effort starting in January 1942. Compton assumed the active direction of the group, which was known by the 'cover-name' of Metallurgical Laboratory of the University of Chicago, which concentrated on development of controlled uranium fission reactors for the production of plutonium. Within the year the first controlled uranium fission reactor was operating at Chicago, this specific project being largely due to the efforts of E. Fermi, L. Szilard, E. P. Wigner, and a host of co-workers. More experimental reactors were designed and built at Oak Ridge, Tennessee, and at the newly established Argonne Laboratory in the suburbs of Chicago. Here was carried out the work which led to the large plutonium-producing reactors built at Hanford, Washington, which produced the plutonium for the atom bomb that destroyed Nagasaki in August 1945.

Throughout the War, Compton also played an important part in the general planning of the atom bomb project, including the setting up of the laboratory at Los Alamos, New Mexico, and in reaching the military–political decisions about the use of the bombs in Japan. He has given a personal account of these matters in his book, *Atomic Quest* (Oxford University Press, 1956).

Compton became chancellor of Washington University in 1945, bringing with him a close associate from the days of his work on cosmic rays, Joyce Stearns, as dean of faculties. He turned with great vigour to the task of re-making a University which had greatly suffered through the depression years and the War years. In eight years filled with hard work he set it along a path toward greatness along which it continues to move. Then in 1953 he asked to be relieved from administrative duties, so that he could return to teaching, and devote himself entirely to problems of the social impact of science and technology, and to ways of promoting world brotherhood and the relieving of international tensions. He was planning to continue active work on such problems into the retirement which ended soon after it began.

He is survived by his wife, formerly Betty Charity McCloskey, and two sons, Arthur Allen, now in the American Foreign Service stationed at Manila in the Philippines, and John Joseph, a professor of philosophy at Vanderbilt University (Nashville, Tennessee), and by a brother, Wilson Compton, now retired, a former president of Washington State University (Pullman, Washington). Another brother, Karl Taylor Compton, former president of the Massachusetts Institute of Technology, died in 1954.

E. U. CONDON

Prof. A. E. Douglass

DR. ANDREW ELLICOTT DOUGLASS, the noted American astronomer and founder of tree-ring-dating research, died on March 20, aged ninety-four.

Dr. Douglass was born in Windsor, Vermont, on July 5, 1867. At the time of his death, he held four titles in the University of Arizona, where he had been a member of the faculty since 1906: professor of astronomy, professor of dendrochronology, and director emeritus of both the University's Steward Observatory and Laboratory of Tree-Ring Research. His professorships had been on a part-time basis in recent years.

Dr. Richard A. Harvill, president of the University of Arizona, writes: "Dr. Douglass was a brilliant scientist who served the University of Arizona with great distinction for fifty-five years. He was highly creative and extremely versatile in the range of his interests and contributions. Throughout the world, when the University of Arizona was mentioned scientific leaders immediately thought of Dr. Douglass. But he was more than a great scholar. He was a man of most admirable personal qualities. He exemplified qualities of simplicity and of humanity that are traits of a truly great man".

Dr. Douglass went to Arizona in 1894 to assist in selecting a site for the Lowell Observatory. After inspecting many locations, he recommended Flagstaff, and the Observatory that later became famous for planetary research was established there on his recommendation. He served as its first assistant observer until 1901.

In that year he became interested in scientific interpretations of relationships between climatic changes and the annual growth of trees, as shown in their growth-rings. His subsequent investigations led to development of a scientific technique to which he gave the name 'dendrochronology'. The technique is used to date fragments of wood by correlation of annual growth-rings of the trees which produced them.

Prof. Douglass joined the University of Arizona faculty in 1906 as head of the Department of Physics. In 1918 he was made director of the University's Steward Observatory and served in that capacity until 1938, when he became director emeritus. The astronomer-turned-dendrochronologist laid the foundations of tree-ring analysis so firmly that he was able to offer a course in the University—the first of its kind—in 1929. By 1935 his research had advanced the technique to a point that made it possible for the University to establish its Laboratory of Tree-Ring Research under his direction.

Prof. Douglass's studies of tree rings became so widely known that they obscured to some extent his earlier prominence as an astronomer. After graduation from Trinity College in Connecticut with a B.A. degree in 1889, he served five years with Harvard Observatory. During that period he was a member of the Harvard–Boyden expedition to South America to select a southern hemisphere astronomical observatory site. He helped in choosing the Arequipa, Peru, site and later served as a member of the Harvard solar eclipse expedition to Chile.

Both the Harvard experience and an early developed interest in the planet Mars served Prof. Douglass well in the selection of the site for the Lowell Observatory. Despite many other activities, he continued his long-term studies of the red planet through the years. In 1924, using the new Steward Observatory 36-in. telescope, he found that melting of the south polar cap on Mars was followed by distinct 'greening' of the planet's dark markings. The University of Arizona instrument showed the green markings so clearly in the 1920's that many 'public night' observatory visitors saw the colour change. Also in 1924 Prof. Douglass first pointed out that Mars may support a low form of organic life—a contention that earned him world-wide scientific attention.

A man of broad capabilities, Prof. Douglass ran for political office in 1902, was elected, and served two terms as probate judge of Arizona's Coconino County. During that period he also laid out the Navajo–Coconino county boundary, taught a year at Arizona State College, Flagstaff, and pursued the early tree-ring studies which he later developed at the University of Arizona. He married Ida Whittington of Los Angeles on August 3, 1905.

Soon after joining the faculty of the University of Arizona in 1906, Prof. Douglass realized the opportunities for astronomical research at the University if a large observational instrument could be obtained. His years of effort on this project culminated in 1916 when Mrs. Lavinia Steward gave the University sufficient funds to establish the Observatory bearing her husband's name. The 36-in. telescope mirror, first of its size made in the United States, was completed and mounted in 1922 under the direction of Prof. Douglass.

During his long and distinguished career, Prof. Douglass served the University of Arizona not only as teacher and scientist but also in two major administrative positions. He was acting president of the University from December 1910 until May 1911, and dean of the College of Liberal Arts during 1915–18.

In the years since Dr. Douglass established the Laboratory of Tree-Ring Research, dendrochronology has made significant contributions to several areas of science. One of his most widely recognized successes came in 1929 when he completed an Arizona climatic sequence extending back to A.D. 700. The achievement made it possible to date more than 30 prehistoric Indian ruins through examination and correlation of cross-sections of beams used in constructing the early Indian dwellings.

Prof. Douglass is survived by his wife, Ida Douglass, and a nephew, Andrew W. Douglass, both of Tucson, Arizona.

NEWS and VIEWS

Royal Society Visiting Professorship :
Prof. M. Szwarc

PROF. M. SZWARC, research professor in the State University College of Forestry at Syracuse University, New York, has been appointed Royal Society visiting professor for the academic year 1962–63. He is expected to take appointment on August 1, 1963, and to work in the Department of Inorganic and Physical Chemistry in the University of Liverpool on ionic and anionic and stereospecific polymerization. Prof. Szwarc has achieved distinction in many fields of physical chemistry and his name is associated with the discovery of the valuable 'toluene carrier gas techniques' for measuring bond dissociation energies and the elucidation of kinetics mechanism. He has also worked on 'living polymers' and electron transfer processes in non-aqueous solutions and is connected with many of the pioneering developments in anionic polymerizations.

Smithsonian Institution Langley Gold Medal :
Dr. H. L. Dryden

DR. H. L. DRYDEN, deputy administrator of the National Aeronautics and Space Administration, has been awarded the Langley Gold Medal of the Smithsonian Institution. The Langley Medal is founded in memory of Samuel Pierpont Langley, pioneer in aviation and secretary of the Smithsonian Institution during 1887–1906. It has previously been awarded only nine times in the fifty-four years since its establishment in 1908, the first being given to the Wright brothers in 1909. Dr. Dryden was selected "in recognition of his important applications of experimental science to the problems of flight and for his wise and courageous administration of much of America's research and technical developments that now make possible the conquest of air and space".

American Geophysical Union Awards

The William Bowie Medal, the principal award of the American Geophysical Union, has been presented to Prof. Sydney Chapman, for "outstanding contributions to the field of astro-geophysics in the course of five decades".

The John Adam Fleming Award for original research in geomagnetism, atmospheric electricity and aeronomy has been presented to Dr. Lloyd V. Berkner, formerly president of the Union. Dr. Berkner is president of the Graduate Research Center of the Southwest in Dallas, and treasurer of the U.S. National Academy of Sciences and chairman of the Academy's Space Science Board.

The James B. Macelwane Award for "outstanding contributions to the geophysical sciences by a scientist under the age of thirty-five" has been presented to Dr. James N. Brune, of Lamont Geological Observatory.

The Commonwealth and International Library of Science, Technology and Engineering

On May 23, the Pergamon Press, Oxford, headed by Robert Maxwell, is launching the new Commonwealth and International Library of Science, Technology and Engineering. The chairman of the Library is Sir Robert Robinson and the executive editor Mr. Cyril W. Wood. The Library, with a target of 1,000 volumes by 1967, contains about fifty subject divisions covering the different branches of science, technology and engineering. Further, in an attempt to broaden the outlook of the scientist, there are included such divisions as liberal studies and the history of science. The editors of the separate divisions have drawn up lists of titles designed to give a continuity of study within each division, and, in those subjects such as mathematics, physics, chemistry and biology, which are taught in schools, this continuity stretches over the age-range of 12+ to that of the honours graduate, thus covering the needs of secondary modern and grammar schools, colleges of technology and universities. Although the Library consists essentially of text-books, some smaller number of monographs on specialist subjects for the postgraduate student will be included. To achieve this continuity of study and to avoid too heterogeneous a collection, all the books of the Library are to be freshly written and are not reprints of existing publications. Furthermore, very close liaison between editors of related divisions is being maintained.

The books will be small, of an average length of 150 pages, and will be published in a common format in two styles—a soft-cover edition within the price-range of 7*s*. 6*d*.–17*s*. 6*d*. (1.25–2.75 dollars) and a more expensive one bound in a hard cover for libraries. Certain important advantages can be claimed for this type of book. The relatively small size makes it possible to select authors who are specialists in the particular section of the subject to be covered. Moreover, a series of small books on a subject can be more easily kept up to date than can one large volume in the same field. Because of the low price, the student may be encouraged to build up a library for himself during his course of study. This last-named objective is an especially worthy one, since too many students, for varying reasons, are now buying either new or second-hand books and discarding or selling them as soon as they have finished the courses which such books cover.

British Iron and Steel Research Association

A Process Physics Section has been set up in the Physics Department of the British Iron and Steel Research Association in place of the previous Metal Physics Section. The new Section is headed by Dr. R. V. Williams, who recently joined the Association from the Thermo-nuclear Section of the Associated Electrical Industries, Ltd., Research Laboratories at Aldermaston. The object of this Section is to study current research in certain new fields such as magneto-hydrodynamics and plasma physics, and to institute a programme of work on projects that show promise of being important to future steelmaking and processing practice. It will also include work on new materials research with special reference to fibrous reinforcement. Work is starting on the following: (1) electric resistance heating of flames using the ionic conductivity in a flame or hot gas as a means of flame or gas temperature boosting; (2) use of electromagnetic effects for control of liquid steel streams; (3) use of steel fibre reinforcement in non-ferrous materials.

New Australian Radio Heliograph

The Commonwealth Scientific and Industrial Research Organization is to build a giant camera for taking detailed radio pictures of the Sun. Construction of the radio heliograph is to be made possible by a gift to the Organization of 550,000 dollars by the Ford Foundation. It will consist of 100 saucer-shaped aerials, each measuring 42 ft. across. These will be arranged in the form of a circle two miles wide. Special receivers and computers will combine the waves received by the 100 individual dishes to give a motion picture of the Sun. The exact location of the new instrument has not yet been decided. It will probably be built at Parkes, N.S.W., not far from the Organization's 210-ft. radio telescope, which was completed last year. Mr. J. P. Wild, leader of the Organization's group studying the Sun, has designed the radio heliograph to give a detailed picture of the radio flares which accompany the explosions near sunspots which can be seen through optical telescopes. All in all, the Division of Radiophysics of the Commonwealth Scientific and Industrial Research Organization has been granted 1,333,000 dollars from American sources (361,000 and 250,000 dollars respectively from the Rockefeller Foundation and the Carnegie Institution towards the cost of the 210-ft. radio telescope, and 172,000 dollars from the National Aeronautics and Space Administration for research on radio antenna systems of advanced design).

Capital Expenditure on Education in Britain

In reply to a question in the House of Commons on May 1, the Economic Secretary to the Treasury, Mr. A. Barber, said that during 1956–57 capital expenditure by public authorities on education in Great Britain was £117 million and present expenditure £546 million, the total representing 3·6 per cent of the Gross National Product. For 1957–58 the corresponding figures were £133 million, £613 million and 3·8; for 1958–59, £134 million and £670 million and 4·0; for 1959–60, £137 million, £742 million and 4·1; and for 1960–61, £133 million, £812 million and 4·2.

Educational Research in Scotland

On May 2, the Under-Secretary of State for Scotland said that Exchequer assistance for educational research in Scotland was normally channelled through the Scottish Council for Research in Education. Work in hand included continued research into intelligence and intelligence tests, the teaching of arithmetic and writing, and the influence of nursery schools on a child's subsequent educational performance. An important project had been initiated, in co-operation with the University of Edinburgh, bearing on educational requirements for success in higher education, and the Scottish Education Department intended to assist directly the University of Aberdeen in research into programmed teaching.

University Development in Scotland

In replying for the Government in a debate on a fifth university for Scotland in the House of Commons on April 19, the Financial Secretary to the Treasury, Sir Edward Boyle, said that the Government's decision that no further universities in England, Wales or Scotland would be nominated before the Robbins Committee reported next year remained firm. He pointed out, however, that pressure on university places was still less severe in Scotland than in England. During the past five years the number of students increased by 20 per cent to more than 18,000, of whom a quarter came from outside Scotland, and Sir Edward anticipated that with the increased Exchequer grants recently announced the Scottish universities and the Royal College of Science and Technology would be able to provide for a further substantial expansion of student members. In addition to these places the central institutions and colleges of further education accommodated 4,000 students in advanced courses, broadly comparable with first degree courses, and this number was planned to rise to 6,000–7,000 by 1970, while the seven teacher training centres, with about 5,500 students, would accommodate at least 6,500 students by 1970. Scotland's needs had been fully recognized, claimed Sir Edward, and the amount allocated to Scotland had risen since last June from £9·3 million to £12·5 million as a result of continuous review by the University Grants Committee.

The University Museum, Oxford

The seventy-third annual report of the delegates of the University Museum, Oxford, for the year ending July 31, 1961, records that the new microbiology building and the extension to the Pharmacology Department came into use during the year. The additional storey on the Lindemann building of the Clarendon Laboratory was completed. In the Museum the first-floor rooms on the north-west side of the court were modified for the purposes of the Scientific Collections Committee by the insertion of an additional floor.

Dinosaurs

The Trustees of the British Museum (Natural History) are supplying a popular demand by the publication of a small pamphlet on dinosaurs. They are fortunate in that it was written by Dr. W. E. Swinton before he left England for an important museum post in Toronto. A brief historical sketch of the group is followed by a general description of dinosaurs and details of the various orders. A final chapter discusses the problem of their extinction. There is a useful note on restorations and a full glossary of the technical terms used in the text. The hand-book is well illustrated, including a coloured plate which accounts for the rather high price. (*Dinosaurs*. Pp. xi + 44 (11 plates). London: British Museum (Natural History), 1962. 5*s*.)

Archæology in Saudi Arabia

Two so-called neolithic collections of flint implements from the southern corner of Saudi Arabia where it borders on the Yemen are described by Philip Smith of the University of Toronto and George Maranjian of the Arabian American Oil Co. in the February issue of *Man*. Some of the tools found are illustrated. Arrow-heads, both leaf-shaped and tongued with barbs, occur, as well as scrapers, grinding stones, etc. No pottery has been found. There is no means of dating these finds and the animal bones recovered are too fragmentary to be identified, but it is thought sheep and goats may occur. Carbon dating for a somewhat similar site east of Jiladah, which was examined by Henry Field, is given as approximately 3,000 B.C. One of these collections has been given to the Peabody Museum at Harvard, the other is on loan to the same museum. Henry Field and F. E. Zeuner have both directed attention to flint tools from this region, but these latest finds are of considerable interest.

Science Abstracts: Subject Index (Section A)

Science Abstracts is published in two separate sections—Section *A* (Physics) and Section *B* (Electrical Engineering). Five-year cumulative author- and subject-indexes for the years 1950–54 have been in preparation since October 1955. The author-index containing approximately 100,000 entries, arranged alphabetically, was published in the autumn of 1956, and the subject-index for Section *B* in April 1959. The new subject-index for Section *A* is now available. It contains more than 100,000 entries arranged under nearly 1,200 different subject headings, and provides comprehensive bibliographies of all subjects covered by the Section. The price is 35*s*. (4.90 dollars) and it can be obtained, together with copies of any of the previously issued cumulative indexes, from the Institution of Electrical Engineers, Savoy Place, London, W.C.2.

Conferences, Meetings and Training Courses in Atomic Energy

The list of *Conferences, Meetings and Training Courses in Atomic Energy* published every two months by the International Atomic Energy Agency is divided into three parts. The first part covers fully all meetings which will be held during the next twelve months, and the second covers meetings during the subsequent twelve months, although in many cases specific information is lacking. This second part is issued in order to assist the planning of future meetings and to prevent duplication. The third part gives specialized training courses at different levels, and some of the sources from which the information has been derived are listed in the annex. The Agency intends this list to be as comprehensive as possible and therefore publishes the fact that it welcomes suggestions and additions giving the fullest information available. The names and addresses of more than forty sales agents for the International Atomic Energy Agency are given at the end of the list. Copies are available from the International Atomic Energy Agency, Kaerntnerring, Vienna 1.

Low-Temperature Physics at Karlsruhe

To mark the installation of the two hundredth Collins helium cryostat manufactured by the A. D. Little Company, a conference on "Low-temperature Physics" was held at the Physikalischen Institut der Technischen Hochschule, Karlsruhe, during March 27–30. It was in the nature of an informal gathering, and it was agreed that no papers presented should be published. In consequence, there was considerable freedom to discuss preliminary results or to indicate the development of apparatus which had not necessarily achieved its final form. Altogether, some 110 people attended, representing fourteen countries, and a useful interchange of information and opinion took place, not only in the two and a half days of formal sessions, but also during the social events of each evening. Visits were arranged to the low-temperature laboratories at the Technischen Hochschule and the reactor establishment near Karlsruhe. The participants enjoyed a stimulating conference with a greater opportunity for informal discussion than is sometimes possible at larger international events. Hospitality was provided by the A. D. Little Company and the conference arrangements were in the hands of Prof. W. Buckel.

Solar Flares and Cosmic Rays

In recent years there has been increasing interest in the observation of cosmic-ray primaries at ground-level following solar flares, and ten such cases have been observed since 1942. M. A. Ellison, S. M. P. McKenna and J. H. Reid have now given a summary of the characteristics of these ten flares, a review of their geophysical effects, and a detailed bibliography (Dublin Institute for Advanced Studies: Observatory of the School of Cosmic Physics. *Dunsink Observatory Publications*, 1, No. 3: *Cosmic Ray Flares*. Pp. 51–88. Dublin: Dublin Institute for Advanced Studies, 1961). The flares observed on the disk were notable for the flash of radiation in Hα occurring in a time of 2 or 3 min., for their large area of order 2,000 millionths of the solar hemisphere, for the twin bright filaments crossing the sunspot group, and for the obscuration of the umbræ with the highest field strengths. The flares occurred near to maximum development of the sunspot groups. All the flares produced sudden ionospheric disturbances and strong radio continuum emission. Some of these flares were among the greatest ever recorded, others were not optically of great importance. The disk co-ordinates of these flares showed remarkable asymmetries in contrast to normal intense flares: there was a strong preponderance to the west limb. All except one occurred north of the solar equator. The implication is that easier and more direct paths to the Earth exist from the north-westerly quadrant of the solar disk, due possibly to the solar rotation and space motion. The authors conclude that the arrival of high-energy particles capable of producing cosmic-ray effects at ground-level is mainly determined by factors other than flare importance, such as the variable magnetic fields in interplanetary space, the disk position of the flare and the magnetic field conditions in the sunspot region.

Joint Health Physics Committee

The Joint Health Physics Committee (the formation of which was noted in *Nature*, **193**, 1136; 1962) is sponsoring a series of symposia on different aspects of health physics during the next two years, the first of which is to be held at the Atomic Energy Research Establishment, Harwell, on June 5 under the title "Provision of Health Physics Services: Problems and Organization". Full details are being sent direct to the members of the collaborating organizations, and if accommodation permits other people will be welcome at the symposium. Further information can be obtained from Mr. W. A. Langmead, Radiological Protection Division, Authority Health and Safety Branch, U.K. Atomic Energy Authority, Harwell, Didcot, Berks.

Paramagnetic Resonance

The first international conference on "Paramagnetic Resonance" will be held in the Hebrew University of Jerusalem during July 16–20. Subjects to be discussed will include: paramagnetic resonance of transition elements—the iron group, the rare earth group, the uranium group, the palladium and platinum group; double resonance ENDOR experiments; theoretical advances in energy-level calculations; resonance spectra of point defects and radiation centres in single crystals; spectra of ion pairs; relaxation phenomena and line shape—correlation with paramagnetic relaxation experiments; correlation of paramagnetic resonance spectra with optical spectra; advances in experimental techniques; influence of electric fields and pressure on paramagnetic resonance spectra. Further information can be obtained from Prof. W. Low, First International Conference on Paramagnetic Resonance, the Hebrew University of Jerusalem, Jerusalem.

Congress of the History of Science

The tenth International Congress of the History of Science will be held at Cornell University, Ithaca, New York, during August 26–31, 1962, and at the American Philosophical Society, Philadelphia, Pennsylvania, during August 31–September 2, 1962. The following subjects will be covered: (I) general problems in the history of science; methods, philosophy and historiography of science; (II) history of technology and applied science; (III) science in antiquity; (IV) science in the Middle Ages and the Renaissance; (V) mathematics and the exact sciences after 1600—(1) history of mathematics, (2) history of physics and astronomy, (3) history of chemistry (including pharmacy); (VI) biological and earth sciences after 1600—(1) natural history and biology (including medical biology), (2) geography, exploration, geology and oceanography; (VII) sciences of man (psychology, anthropology, sociology, linguistics). Further information concerning presentation of papers and attendance can be obtained from the secretary, Dr. C. Doris Hellman, Tenth International Congress on the History of Science, Cornell University, Ithaca, N.Y.

The Association of Consulting Scientists

The following officers and members of Council of the Association of Consulting Scientists have recently been elected: *Chairman*, Dr. M. Barent (Barent and Johnson); *Vice-Chairman*, Mr. F. G. Sarel Whitfield (Avebury Research Laboratories, Ltd.); *Hon. Treasurer*, Dr. G. W. Ferguson (Parry and Ferguson); *Hon. Secretary*, Mr. W. H. Stevens (Park House, Hawthorne Road, Bromley, Kent); *Members of Council*, Dr. H. H. Chambers (Sondes Place Research Laboratories, Ltd.), Dr. G. P. L. Miles (G. P. L. Miles), Dr. R. F. Milton (R. F. Milton), Mr. H. Pritchard (H. Pritchard), Mr. A. N. Worden (Huntingdon Research Centre).

The Royal Institution, London

At the annual meeting of the Royal Institution on May 1, the following officers were elected: *President*, Lord Brabazon of Tara; *Treasurer*, Mr. W. E. Schall; *Secretary*, Brigadier H. E. Hopthrow; *Managers*, Dr. A. Clow, Sir Harold Roxbee Cox, Mr. E. R. Davies, Dr. T. F. Gaskell, Prof. A. G. Gaydon, Prof. Alex. Haddow, Miss E. Henrietta Jebens, Mr. L. B. W. Jolley, Dame Kathleen Lonsdale, Dr. H. Lowery, Mr. Percy H. Schwarzschild, Mr. W. R. Stevens, Mr. Cyril Sweett, Wing-Commander H. F. Tiarks and Prof. W. D. Wright; *Visitors*, Mr. A. D. R. Caroe, Mr. Norman Clarke, Miss F. M. Eastwood, Mr. A. H. Ewen, Mr. G. J. Gollin, Mr. F. Greenaway, Mr. C. R. Hopper, Mr. S. Rees Jones, Mr. W. C. Lister, Miss E. Whittall, Mr. F. Poperwell, Dr. A. A. Moss, Dr. H. R. Rishworth, Miss D. Sidebottom and Mr. H. Stanesby.

National Research Council of Canada

The following have been appointed members of the National Research Council of Canada for a three-year term: Prof. F. A. Forward, head of the Department of Mining and Metallurgy, University of British Columbia; Dr. F. K. Hare, dean of the Faculty of Arts and Science, McGill University; Dr. G. A. Krotkov, head of the Department of Biology, Queen's University at Kingston; and Mr. W. F. McLean, president of Canada Packers, Ltd., Dr. F. R. Hayes, head of the Department of Biology and director of the Oceanographic Institute, Dalhousie University, has been re-appointed to the Council for a further three-year term. The new appointments fill vacancies caused by the retirement from the Council of Dr. I. McTaggart Cowan, University of British Columbia; Dr. A. D. Misener, director of the Ontario Research Foundation; Dr. B. W. Sargent, Queen's University at Kingston; and Dr. D. L. Thomson, McGill University. Dr. R. J. Uffen, principal of University College, University of Western Ontario, has been appointed to four of the Council's executive committees.

The Night Sky in June

New moon occurs on June 2d. 13h. 27m. U.T. and full moon on June 18d. 02h. 03m. The following conjunctions with the Moon take place: June 5d. 03h., Venus 4° N.; June 21d. 07h., Saturn 0·5° S.; June 23d. 12h., Jupiter 2° N.; June 28d. 10h., Mars 5° N.; June 29d. 18h., Aldebaran 1° S.; June 30d. 06h., Mercury 0·8° N. In addition to these conjunctions with the Moon, Venus is in conjunction with Pollux on June 11d. 19h., Venus being 5° S. Mercury is too close to the Sun for observation. Venus is an evening star, visible in the west after sunset. It sets at 22h. 40m., 22h. 40m. and 22h. 25m. on June 1, 15 and 30, respectively; its stellar magnitude is −3·4. Its distance decreases during the month from 127 to 109 million miles and the visible portion of the apparent disk decreases from 0·847 to 0·757. Mars is still too close to the Sun for easy observation, rising about two hours before the Sun on June 15. Jupiter rises at 0h. 55m., 0h. 00m. and 23h. 00m. at the beginning, middle and end of the month, respectively. It is in Aquarius, its stellar magnitude is −2·1 and its distance from the Earth in the middle of the month is 440 million miles. Saturn is in Capricornus, rising at 23h. 50m., 22h. 55m. and 21h. 50m. on June 1, 15 and 30, respectively. Its stellar magnitude is +0·7 and its distance from the Earth on June 15 is 860 million miles. There are no occultations brighter than magnitude 6 visible at Greenwich. The summer solstice occurs on June 21d. 21h.

Announcements

Prof. Léon Van Hove, leader of the Theory Division at CERN, has been awarded the Dannie Heineman Prize for mathematical physics by the American Physical Society and American Institute of Physics for his contributions to statistical mechanics and to field theory, as examples of outstanding publication in the field of mathematical physics.

Mr. B. S. Shenstone, a director and chief engineer of British European Airways, has been elected president of the Royal Aeronautical Society for 1962–63. Born in Canada, Mr. Shenstone graduated at the University of Toronto. He is also vice-chairman of the Society's Man-Powered Aircraft Group Committee.

Mr. Richard Hindle Fowler has been appointed director of the Institute of Applied Science of Victoria, Melbourne. Mr. Fowler, who has been assistant director of the Institute since 1956, succeeds Dr. C. M. Focken, who has retired.

The annual meeting and summer conference of the Society for Applied Bacteriology will be held in the School of Agriculture, University of Nottingham, during July 17–19. Included in the meeting will be a symposium on "*Staphylococci* and *Micrococci*". Further information can be obtained from Dr. Ella M. Barnes, Low Temperature Research Station, Downing Street, Cambridge.

A two-day summer meeting of the Royal Meteorological Society will be held in the University College of North Wales, Bangor, during July 5–6. The programme will include two symposia on "The General Circulation of the Atmosphere" and on "The Electrification of Thunderstorms". Further information can be obtained from the Assistant Secretary, Royal Meteorological Society, 49 Cromwell Road, London, S.W.7.

The 1962 National Bureau of Standards course in "Radio Propagation" will be held during July 16–August 3, 1962. The course, administered by the National Bureau of Standards, Boulder, Colorado, Laboratories, is open to scientific and engineering personnel in other Government agencies, industry, or universities. Further information can be obtained from the National Bureau of Standards Office of Technical Information, U.S. Department of Commerce, Washington 25, D.C.

An international conference on "The Physics of Semiconductors", arranged by the Institute of Physics and the Physical Society on behalf of the International Union of Pure and Applied Physics and the British National Committee for Physics, will be held in the University of Exeter during July 16–20. Further information can be obtained from the Administration Assistant, the Institute of Physics and the Physical Society, 47 Belgrave Square, London, S.W.1.

Erratum. In the communication entitled "Electron-Diffraction Studies of Fatty-Acid Monolayers", by B. R. Banerjee, B. Ostrofsky and H. E. Ries, jun. (*Nature*, 193, 873; 1962), lines 14–17 in the second column of p. 874 should read: ". . . to the orientation indicated by the spots. Fig. 4, after collapse at 42 dynes per cm., shows no evidence for orientation; the sharp and continuous diffraction lines suggest random orientation and thicker films".

BRITISH POST OFFICE AND TELECOMMUNICATIONS SERVICES

IN a debate on the Post Office in the House of Commons on March 28, the Postmaster-General, Mr. R. Bevins, said that out of capital expenditure of £132 million during 1962–63, Britain will spend about £122 million on telecommunications, or 11 per cent more than in the present year, partly in modernizing the system as new techniques developed, by automatization through the development of subscribers' trunk dialling, by new international cables and, in the long term, by satellites, and partly in reducing the waiting list. Inland trunk traffic is growing at the rate of about 12 per cent a year, and by the end of next year there will be about 37,000 trunk circuits as against 24,000 three years ago. It is planned to make subscriber trunk dialling available to about 90 per cent of subscribers by 1970, and it is estimated that savings to subscribers during 1962–63 on the same number of calls as with the old tariff will be £7 million. The waiting list has been reduced in six years from 250,000 to 53,000. Later this year Britain will be opening the first electronic exchange in Europe to carry public telephone calls. Present techniques, said Mr. Bevins, limited to about 100 the number of telephone systems which can be carried by long-distance submarine cables, but a cable in the design stage might increase this to about 250. Traffic demands in ten or twenty years time are likely to justify the high cost of communication satellites, which can probably offer 1,000 simultaneous telephone calls and perhaps a television channel. He hoped that the Commonwealth will play its part in this, and he had welcomed representatives from all Commonwealth countries who had come to consider Commonwealth policy. Britain is also co-operating with the Americas in test transmissions through satellites, but we may be many years away from a full, universally operated system.

In the debate, Mr. P. Holland asked for some information on the experiments in automation being conducted at Luton and Norwich, but this point was not covered in a full reply on the debate by the Assistant Postmaster-General, Miss M. Pike, who, however, instanced the new telephone exchange at Altrincham and the head post office at Hitchin as illustrating the possibilities of introducing new ideas and techniques into post office buildings. Both buildings were designed by a special research team, a joint enterprise with the Ministry of Works. A large-scale experiment covering parcel post for the whole of East Anglia is planned to start this year, and the Post Office is experimenting with the sorting and segregation of mail as well as with the sorting of parcels. Demand for telex has doubled in the past four years, and 1,600 new lines during 1962–63 will bring the total to more than 10,000. About 20,000 subscribers are expected by 1970, and to cope with this growth 21 new telex exchanges will be required; work on six will be started during 1962–63. Referring to the Post Office's increasing concern with the transmission of data and the use of telecommunications networks, Miss Pike stressed the need for ensuring a background of submarine communications throughout the Commonwealth. Despite its huge effort in developing satellite communications, the American Telephone and Telegraph Company has decided not to change its large investment in plans in submarine cables between now and 1965–66.

PREPARATION OF SCIENTIFIC REPORTS AND BOOKS

THE theme of this year's conference of the Scottish Branch of Aslib (Association of Special Libraries and Information Bureaux) was the writing, editing, publishing, binding and storage of the technical report. The meeting was of a historic nature as it was the first two-day residential course which the Scottish Branch has held. To enable as many as possible to attend, it was held in Perth, once the capital of Scotland and a point easily reached from all parts of the country. The meeting was accorded a civic reception from the Lord Provost of Perth, Mr. John T. Young, and the magistrates.

The first speaker was Dr. Archie Clow, producer-in-charge, Science Unit of the British Broadcasting Corporation, who spoke on "Communication in Science". Dr. Clow said that his experience over the past ten years was that interest in science in the public as a whole is very high. Dr. Clow spoke on the need for careful writing and editing of a broadcast science talk pointing out that the speaker had to do everything possible to maintain the flow of thought. The listener could not stop the speaker and ask for explanations or, as in reading, turn back the pages. In one aspect broadcasting did not differ from other forms of communication and that was intelligibility in the sense of what the listener could recall an hour or a week later. He agreed that there was a great need to present the hard dry bones of scientific investigations with imagination.

The second paper was "The Editorial Function", which was given by Mr. G. N. J. Beck, assistant editor of *Endeavour*, who is principally concerned with the production of the foreign-language editions of that journal. He spoke on the choice of the subject of articles and their commissioning from suitable authors. He outlined how the flow of material was kept going between the editorial offices and the printers of the foreign issues. Pointing out that they used the services of translators belonging to the countries covered, he indicated the occasional difficulties that arose in translation of an idiomatic phrase comprehensible to the original author but of which a literal translation would mean nothing. He also emphasized the need for clear and intelligent writing and proof reading.

Mr. D. Ainslie Thin, director of Messrs. Oliver and Boyd, Ltd., followed with a talk on "Publishing Scientific and Technical Material". Mr. Thin dealt with scientific material from the publishers' point of view. He spoke of author's royalties and the need for modern attractive book jackets. He also referred to the vexed subject of indexes, which was later a matter for discussion from the floor. It was a question of whether or not it was better for the author or a trained indexer to do this work. Mr. Thin went into detail on the various stages in the publication of a book, the necessity for a clear layout, illustrations to match the text, type faces to be used and so on. It was suggested to him that it would be useful if publishers were to print the bibliographical detail on the flyleaf and to indicate the font-type used. The first of these suggestions he thought to be a useful one, but doubted if it would be practical to elaborate on the type as in some books several fonts were used. Mr. Thin also went into the question of the age of books and stocks. One suggestion from the floor was that when a publisher saw his stock of a particular book running low he should consider the advisability of making a microfilm of it. He again spoke of the difficulty met in the publication of a translated version of a book. It was sometimes difficult to get the translator and the author to agree on the final version to be issued.

At the end of the first day there was some time given for discussion. In addition to the items already mentioned the question of the use of microfilm was also raised. It apparently is still not quite acceptable to the average scientist, who prefers paper in his hands. There was also some discussion on the need and methods for getting information over to the working man at the factory bench. Dr. Clow had found there was interest expressed in the broadcasts, but it was essential that the correct speaker was employed to present the matter in an interesting way.

The second day of the conference opened with a talk by Mr. David Moncur, manager, Dunn and Wilson's, Falkirk. Mr. Moncur, who illustrated his talk with a series of transparencies, went into elaborate detail of the process of binding books and periodicals in Britain. He spoke of a recent visit to the United States where the process of binding had been streamlined but had poor effect. One library he spoke of had all its books bound in one colour, which was extremely monotonous to the eye. In Britain much is done to vary the colour. Mr. Moncur also spoke of the new trends in binding by the use of plastic sleeves and front boards.

The final paper of the day and of the conference was given by Dr. D. J. Urquhart, director of the National Lending Library at Boston Spa. He dealt with the availability and translation of foreign publications. He spoke on the building up of the National Lending Library and its endeavour to provide a 48-hr. service to borrowers. He pointed out that the person who worked in a sizeable research organization and perhaps had access to big libraries was better off than he who worked in a small industry remote from technical college and university libraries. He thought that the public libraries had a great responsibility to increase their guides to scientific literature, supplying the basic reference tools and using the resources available to them through Boston Spa. Reference was also made to the Russian translations held at Boston Spa and how they were available to borrowers.

THE EAST AFRICAN VIRUS RESEARCH INSTITUTE

IN his annual report*, the acting director of the East African Virus Research Institute, Dr. J. D. Gillett, explains that the middle of Africa is the home of many different virus diseases, particularly those which are transmitted to man by mosquitoes. It is not enough merely to study virus, vector and vertebrate host, including man, as separate entities. These, their predators and parasites, their associated plants and, indeed, the whole community of living things must be considered, together with the physical environment, as a single interacting system. It is only thus that one can begin to understand the nature of the complex factors which play a part in the maintenance of virus populations, and of the variations in these factors which lead to the infection of man from wild animals and bird hosts, or to the sudden occurrence of human epidemics. It is only by such a broad approach that explanations will be found for 'epidemic years'. While the paucity of technical facilities for virus research in Africa is well known, the richness in natural facilities is unsurpassed anywhere.

The approach to virus research in Africa must be mainly ecological. If, however, it is to avoid the danger of becoming merely descriptive, field observation must be supported by laboratory experiments whenever possible. Laboratory studies, if properly planned, can produce short-cut answers and suggest valuable clues to complex problems of behaviour. It would be difficult to find a better place for this complementary approach to virus studies. New viruses are being discovered every year. Ten years ago these were mostly being recovered from wild populations of mosquitoes, and their importance to man was largely unknown. With the development of new techniques, however, emphasis has swung more and more to the human patients themselves as a source of new viruses, and now the Institution is in a position to find the cause of many fevers which previously would have been accepted as pyrexias of unknown origin. Many new viruses and virus strains are being discovered. Most of the fevers associated with these newly discovered viruses are relatively mild, or their unpleasant symptoms pass off without permanent after-effects. Apart from individual discomfort, their main importance would appear to be the economic loss to the country concerned that must accompany wholesale absence from work.

The most dramatic of these new virus infections has been the huge epidemic of o'nyong-nyong. This appears to have begun in Uganda in 1959, moved steadily forward in a south-easterly direction for about a year and then, coming up against natural ecological barriers to spread farther in that direction, halted before breaking out in separate foci many hundreds of miles apart. The line of the initial advance depended on almost continuous permanent concentrations of the main vector, the malaria mosquito,

Anopheles funestus, and its limits and extent could be fairly accurately forecast by a study of endemic malaria conditions. Its present distribution in isolated pockets appears to have resulted from lines of human communication, such as steamers on Lake Victoria and railways from the lake ports. The appearance of the disease in epidemic form, however, has finally depended on the appearance of the main vector in high concentration, and of course, on a non-immune susceptible human population.

O'nyong-nyong virus is very closely related to chikungunya virus, which was isolated for the first time in 1953 during an epidemic in Tanganyika; the symptoms of infection in man are very similar indeed, and resemble those of dengue. Furthermore, infection from either virus produces hæmagglutination, inhibiting antibodies to both viruses. It is interesting to note, however, that, so far, o'nyong-nyong virus has in every instance been associated with the two main malaria mosquitoes, *A. funestus* and *A. gambiae*, whereas chikungunya outbreaks can appear in the absence of these species. Moreover, both o'nyong-nyong and chikungunya are occurring in contemporaneous, but spatially separated, epidemics. If these two agents are merely variants, does the insect host play a part in bringing about selection for one or the other ? Are these extra-human cycles in other vertebrates, and, if so, are they the same for each virus ?

Dr. Gillet indicates that the most important development of the year has arisen from the observation that the distribution of a malignant lymphoma in African children coincides with that of certain arthropod-borne diseases such as yellow fever. Thus a possibility exists that this revolting fatal disease is arthropod-borne, or at least associated with arthropod-borne disease. This is at present no more than a slender clue, but one which is being followed up vigorously. Work on this important subject is likely to proceed if the close collaboration of a team of cancer experts can be secured. In the meantime, the investigators have been screening several sera from cases and relatives against a range of viruses, in an attempt to demonstrate antibodies that would indicate previous implication of an arthropod-borne virus. So far, these have given largely negative results, except for Bunyamwera virus, where antibodies have been demonstrated in a suggestively high proportion. Further information is urgently needed on the general distribution of Bunymwera antibodies in the human population before any conclusions can be made.

THE REGIONAL RESEARCH LABORATORY, HYDERABAD

THE annual report for 1960–61 of the Regional Research Laboratory, Hyderabad, follows the broad pattern of previous years*, but the presentation is addressed more particularly to the general reader. Lists of publications during the year and of patent applications filed and accepted are appended, as well as of staff and of members of the Executive Council and its sub-committees.

Work in the Division of Oils and Fats included hydroxylation and descriptive studies on castor oil, ricinoleins as surfactant bases, the processing of cotton-seed and tallow-like products from cotton-seed oil, the hydrogenolysis of fatty acids, fat-splitting and distillation of fatty acids, and fundamental studies on autoxidation. In the Division of Surface Coatings and Pigments, besides fundamental studies on dehydrated castor oil, the styrenation of drying oils, the preparation of long oil alkyds from drying-oil fatty acids, of emulsion paint vehicles from alkyds, and of varnishes from cashew nut-shell liquid and drying oils, the use of styrene–cardanol co-polymers in surface coatings and exposure tests for composite aluminium, red lead and other conventional primers were all investigated.

In organic chemistry some twenty-one *N*-(alkylaminoalkyl)-1:2:3:4-tetrahydroquinolines were synthesized for pharmacological examination, a number of *N*-dialkylaminoalkyl-β-phenylethylamines were prepared, as well as terpineol and terpin hydrate from 3-carene and pimenes. In entomology, the mechanisms of synergism of sesamin, 'Sesoxane', piperonyl butoxide and other insecticides were examined, as well as the mechanism of physiological action at different temperatures of toxaphene and pyrethrum, and the effect of X-rays on the biology and biochemistry of the spermatozoa of insects and mammals. The mechanism of biosynthesis of itaconic acid was further examined, as well as the uptake of phosphorus-32 and of labelled glucose by *Escherichia coli* in the logarithmic phase of growth, the nucleic acid and protein metabolism of liver cells in suspension. Electrophoretic studies of proteins before and after treatment with acid and studies of the metabolism of proteins and nucleic acid in bovine spermatozoa also continued.

Other work was concerned with the utilization of Indian cotton linters, the production of hand-made paper of high bursting strength, the recovery and fractionation of tar acids from tar oils and ammoniacal liquor, the chemical examination of tar acids from low-temperature tar, distillation characteristics of low-temperature tars and pilot-scale distillation of these tars, as well as low- and medium-pressure hydrogenation of low temperature tars and oils. Electrode binder and electrode coke were prepared from these tars, and spectrophotometric studies made of tar acids obtained by low-temperature carbonization. Further work was carried out on the production and development of active carbons and on bleaching earths for vegetable and mineral oils. A molybdenum cobalt oxide on alumina catalyst was prepared for the hydrogenation of tar oil as well as one on silica alumina and a nickel oxide on alumina catalyst. Other work was concerned with the hydrolysis of titanium salts, the preparation and properties of butyl titanate, white cement, the synthesis of silicon carbide, active carbons for water treatment, the treatment of boiler feed water, vapour-phase esterification, and design and development studies on benzyl chloride, phenylacetic acid and phenylacetamide.

HIGH-ENERGY RESEARCH AT CERN

THE monthly, *CERN Courier*, which was temporarily suspended during 1961, made a welcome comeback at the beginning of 1962. The January issue (2, No. 1; 1962) contains, in addition to a message from Prof. V. F. Weisskopf, the director-general of the European Organization for Nuclear Research (CERN) at Meyrin near Geneva, a comprehensive article by J. Baarli, the head of the health physics division, on radiation safety at CERN. Some 800 people out of a total personnel of 1,440 are subject to permanent radiation control. They are those who work either directly with radiation or in areas where a radiation dose-rate exceeding normal background has been measured. They carry γ-film badges and in the case of about 150, neutron film badges in addition. The records for 1960 show that the maximum radiation exposure for more than 700 of the 800 controlled personnel was less than 1 rem and only one person had an exposure exceeding 5 rems. During 1961 there was a somewhat greater exposure, especially of those groups who carried out maintenance work and repair on the synchro-cyclotron accelerator, but it was still below the recommended maximum permissible radiation exposure. Other articles in the January issue include reports on the 1961 international conference on theoretical aspects of very high-energy phenomena held at CERN during June 5–9, 1961, and on the twelfth Solvay Physics Meeting held at the Free University of Brussels during October 9–13, 1961.

The first part of an article based on a paper prepared by the director-general for the twentieth session of the CERN council meeting on December 19, 1961, entitled "CERN and High-Energy Physics" is the main feature of the February issue of the *Courier*. Prof. Weisskopf, after outlining the present state of high-energy physics, considers the activities of the different high-energy research centres, particularly those contributions which have opened new avenues of research or revealed decisive results.

The main aim of high-energy physics is the study of the properties of elementary particles, and large high-energy installations are required because the smaller the object, the higher is the energy needed to penetrate into its structure. Studies to date have not yet given satisfactory answers as to the structure of the particles, but they have revealed an unexpected wealth of phenomena—nucleon structure, strange particles, weak interactions, and anti-matter—which represent a new aspect of nature, very different from experiences at lower energies.

The work with the synchro-cyclotron at CERN has been directed mainly towards weak-interaction physics, and the first important contribution was the discovery of the electron decay of the pion in 1958. Following the addition of a muon channel, the first measurement of the anomalous magnetic moment of the muon was made, and at present measurements of muon capture by hydrogen are being carried out. The proton synchrotron, which came into use in 1960, has been used for the study of peripheral collisions, and a number of new phenomena relevant to the understanding of the pion-cloud structure has been demonstrated. Experiments planned for the immediate future include the neutrino experiment, in which a neutrino beam of high energy is obtained when fast pions produced in a target decay in flight, and runs with the 81-cm. bubble chamber in a separated anti-proton beam of more than 3 GeV., in order to obtain pictures of annihilations of fast anti-protons and their by-products.

S. WEINTROUB

DAYTIME SKY RADIANCE FROM FORTY TO EIGHTY THOUSAND FEET

By GORDON A. NEWKIRK and JOHN A. EDDY*

Department of Astro-Geophysics, High Altitude
Observatory, Boulder, Colorado

THE possibility of flying large astronomical equipment on balloons to altitudes of 80,000–100,000 ft. has led to increased interest in the radiance of the sky at these altitudes. The daytime sky radiance is of interest to the instrument designer, who is concerned with the contrast between the target (for example, a planet, artificial satellite, the solar corona, etc.) and the sky. It is of equal interest to the astronomer, who can learn about the sedimentation of micrometeorites through the upper atmosphere by means of the scattering of sunlight from meteoric debris, and to the meteorologist.

As part of a programme to investigate the feasibility of coronal observations from balloons, the High Altitude Observatory has flown an externally occulting coronagraph up to heights of 82,000 ft. to measure the angular and the wave-length distribution of the daylight sky. The coronagraph was a modification of the instrument designed by Evans[1] and used by one of us[2] for ground-based observations of the solar aureole. The balloon-borne instrument was pointed at the centre of the solar disk to within an accuracy of ± 1 min. of arc by the guiding gimbals developed and used in Project Stratoscope[3–6].

The sky radiances were recorded in three ways: (1) photographically, at scattering angles $\varphi = 9 \cdot 6°$, $20 \cdot 7°$, $31 \cdot 4°$, $40 \cdot 6°$, and $57 \cdot 8°$ at $\lambda = 0 \cdot 44\mu$ with electric vector vibrating perpendicularly to the scattering plane; (2) photographically, at scattering

---

* Present address: National Bureau of Standards, Boulder, Colorado.

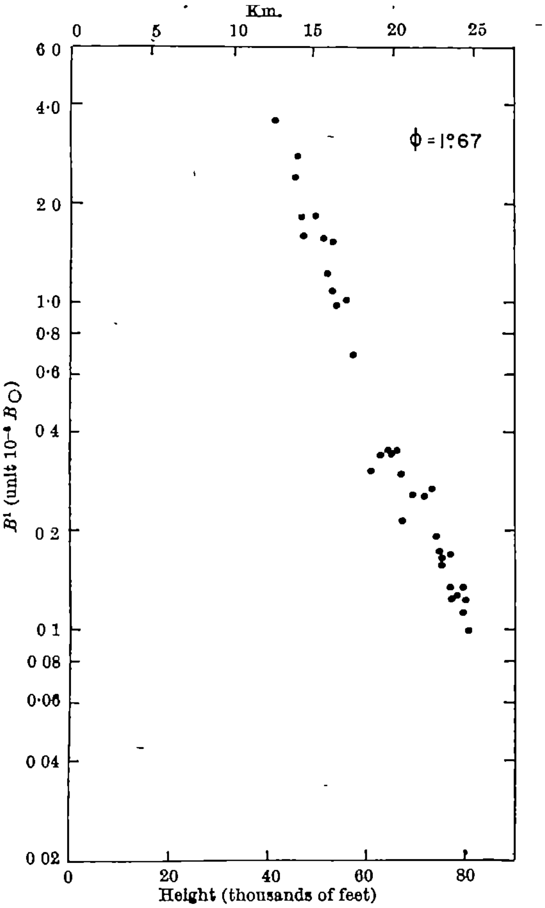

Fig. 1. Daytime sky radiances with electric vector perpendicular to the scattering plane at scattering angles φ at $\lambda = 0{\cdot}44\mu$. Measured photographically on October 3, 1960

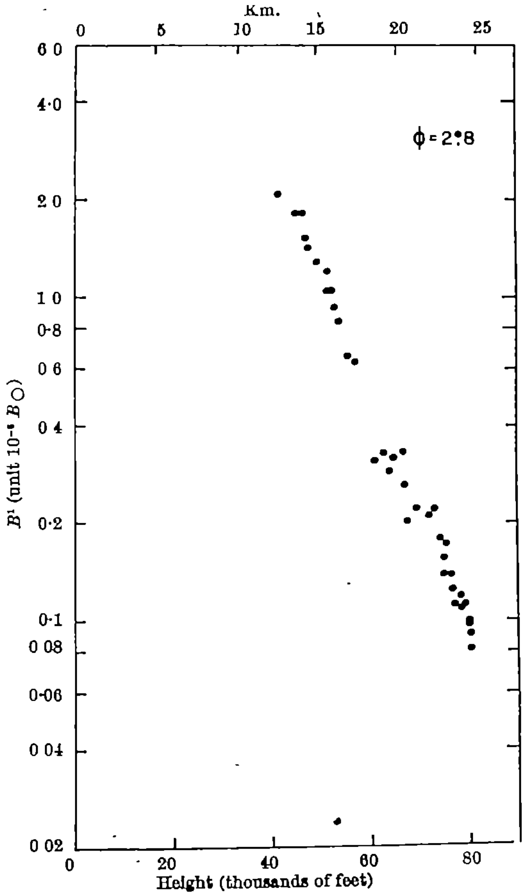

Fig. 2. See legend to Fig. 1

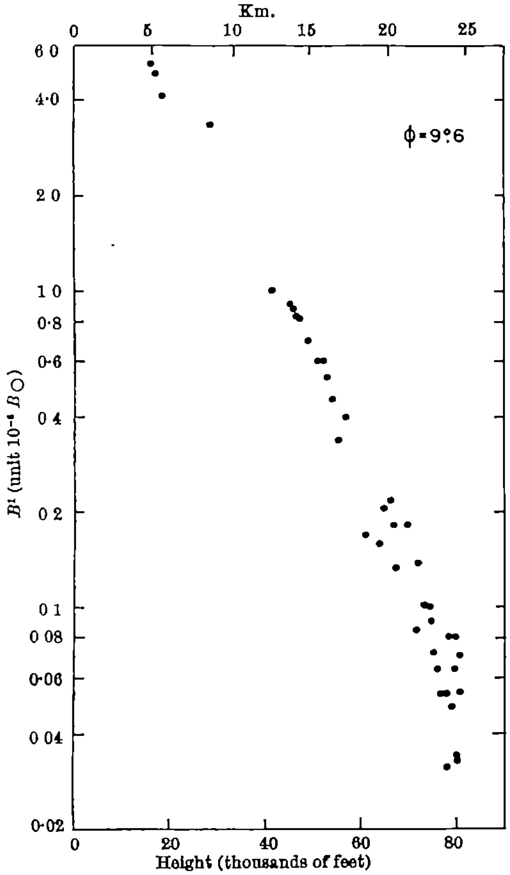

Fig. 3. See legend to Fig. 1

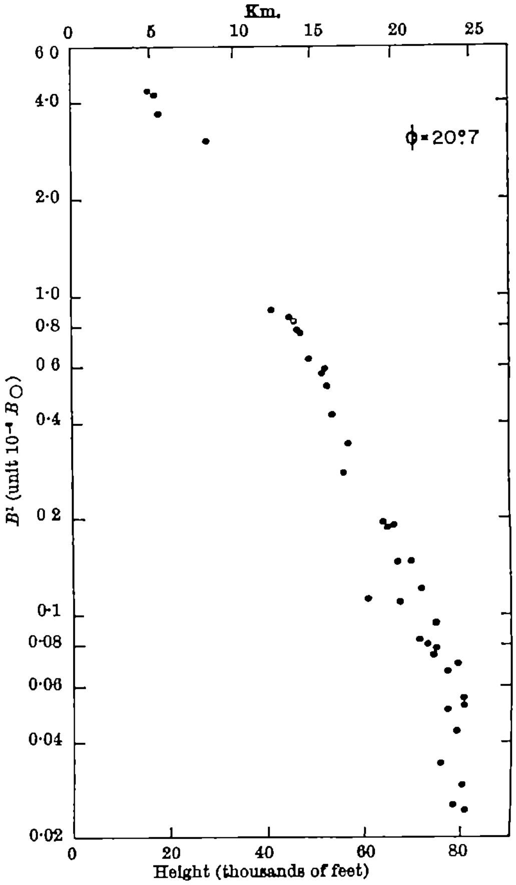

Fig. 4. See legend to Fig. 1

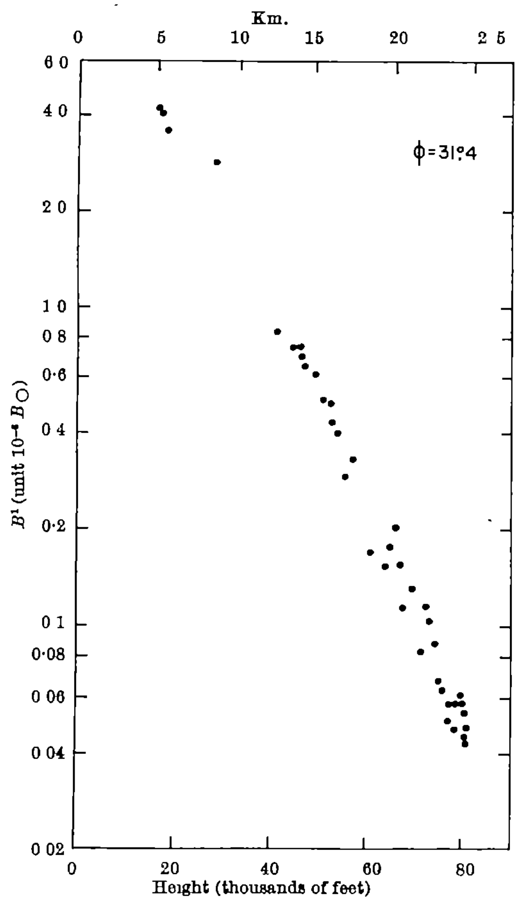

Fig. 5. See legend to Fig. 1

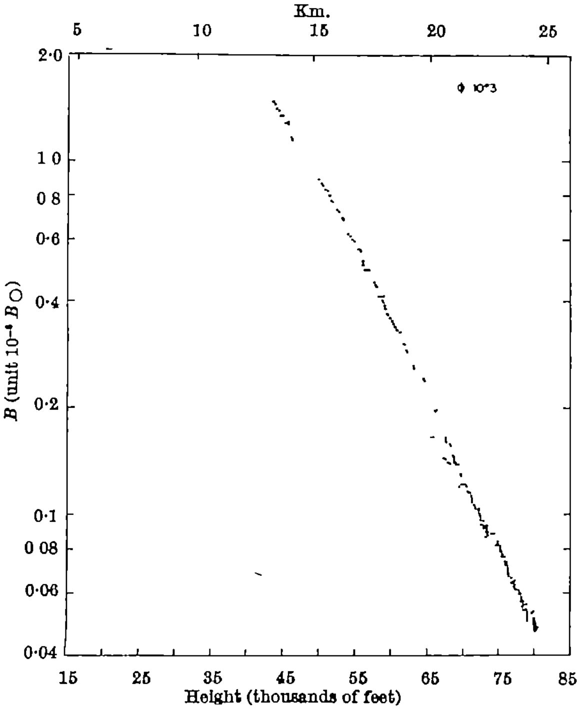

Fig. 6. Total daytime sky radiance at $\lambda=0\cdot52\mu$ at a scattering angle of 10·3° from the solar centre. Measured photoelectrically on October 3, 1960

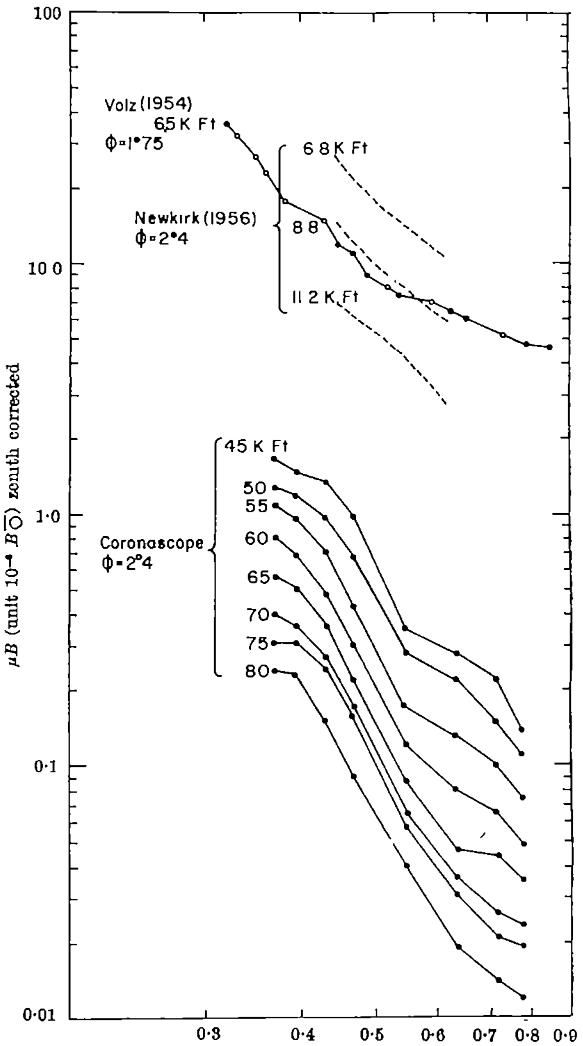

Fig. 7. Spectral energy distribution of the total daytime sky at a scattering angle of 2·4° as measured on October 3, 1960, and corrected to the zenith by multiplication by $\mu=\cos Z_0$. The results are compared with earlier observations at low altitude (refs 2 and 8)

angles from 1·67° to 2·8° with a low-dispersion spectrograph covering λλ 0·37–0·79μ; (3) photoelectrically, at a scattering angle 10·3° at λ = 0·52μ.

The spectrograph and the photoelectric photometer recorded total radiance. Standardization was provided by a sunlit, calibrated, opal glass and step wedge combination that was photographed simultaneously with the spectrograph and the 9·6°–57·8° fields. The photoelectric photometer was standardized frequently in flight with a calibrated opal illuminated by sunlight.

In view of the potential usefulness of these results, we present some of the measurements made on our more successful flight, that of October 3, 1960, without interpretation (Figs. 1–7). All values are given in units of the radiance of the mean solar disk at the height of observation. Two points should be noted. First, during the ascent of the equipment from 53,000 to 80,000 ft. and the descent from 80,000 to 40,000 ft., the zenith distance of the Sun was, of course, changing. Secondly, the observations are made in neither the vertical nor the horizontal circle through the Sun, but in an instrumental plane in-

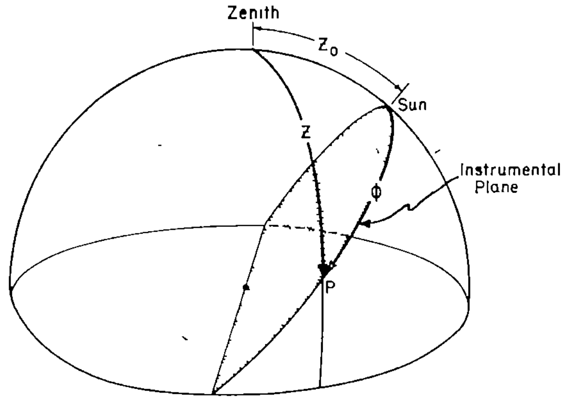

Fig. 8. Relation between the zenith angles and the scattering angle φ on the celestial sphere

clined to the horizontal and including the Sun. The relation between the solar zenith angle Z_0, the scattering angle φ and the zenith angle Z of the point P in the sky is displayed in Fig. 8. Table 1 gives a brief résumé of the quantities $\mu_0 = \cos Z_0$ and $\mu = \cos Z$ for 10,000-ft. intervals during the flight.

Table 1. TABLE OF COSINES OF ZENITH DISTANCE AT SCATTERING ANGLES φ, OCTOBER 3, 1960

Height (10^3 ft.)	Central standard time	$\varphi = 0$	$\varphi = 2\cdot8°$	$\varphi = 9\ 6°$	$\varphi = 20\ 7°$	$\varphi = 31\ 4°$
60	09 · 40	0 539	0·533	0 532	0 505	0 497
70	10 · 00	0 572	0 572	0 565	0 587	0 525
80	10 : 30	0 615	0 615	0·607	0 576	0 560
80	11 : 50	0 662	0 662	0 653	0 620	0 598
70	14 · 36	0 481	0 480	0 474	0 451	0 450
60	15 10	0 404	0 404	0 399	0 379	0 386
50	15 44	0 316	0 315	0 311	0 296	0 312
40	16 01	0 267	0 267	0 263	0 250	0 271

The scatter in the photographic measurements is sufficient to mask the small difference between the observations made during ascent and descent. The photoelectric observations (Fig. 6) are more accurate; the ascent branch, beginning at 66,000 ft., can be distinguished lying slightly below the descent branch. The difference is a result of the difference in zenith distance between the two branches.

It is of interest to compare these observations with the sky radiance expected from a pure, molecular sky at, say, 80,000 ft. Within the first two degrees of the Sun, the sky is approximately twice the Rayleigh value. At a scattering angle of 10° the observed radiance exceeds the Rayleigh value by only about 10 per cent. At 20° and beyond the two are nearly indistinguishable.

The only other observations which describe even roughly the quantities reported here are those published by Stakutis[7]. A detailed comparison is impossible because the wave-length at which the latter observations are made is not specified. However, his minimum radiance in the neighbourhood of the Sun is 10^{-5} at 98,000-ft. altitude. Our observation at $\lambda = 0{\cdot}52\mu$ at 80,000 ft. gives a radiance 5×10^{-8}, a factor of 200 smaller.

This work was supported by the Office of Naval Research under contract *Nonr* 393(05).

GEOMAGNETIC MICROPULSATIONS WITH PERIODS 0·3-3 SEC. ('PEARLS')

By PROF. J. A. JACOBS and E. J. JOLLEY

Institute of Earth Sciences, University of British Columbia, Vancouver, Canada

GEOMAGNETIC micropulsations of nearly sinusoidal shape and with periods ranging from about 0·3 to 3 sec. have been called 'pearls'. The wave-trains usually exhibit beats—the envelope of a sequence of oscillations resembling a necklace of oval pearls. It is because of this resemblance that Troitskaya[1] has named this phenomenon pearls. The pulsations may occur as separate bursts lasting 1–2 min. and as a continuous series of pulsations lasting for an hour or more. Fig. 1 shows an example of pearls recorded at Abbotsford, British Columbia. The curves show pearls in their pure form, longer-period pulsations which were also present having been filtered out. The appearance of pearls is not very common. Benioff[2] observed that over the four-year period 1955—59 the number of occurrences in Southern California was about 30 a year. This number may only be representative of low-middle latitudes and may be increased by a factor of two or three in the polar regions[3].

During the course of a combined field operation in the summer of 1960, pearls were recorded once at Abbotsford during two weeks of continuous operation. The onset of pearls at Suffield, Alberta, some 450 miles to the east, was not simultaneous, but occurred 38 min. earlier. At Austin, Texas, they were not observed at all. Records were obtained from Benioff for Isabella (California), Ruth (Nevada), Huancayo (Peru), Reykjavik (Iceland) and Uppsala (Sweden). (The latitudes and longitudes of these stations are given in Table 1.) It appears that pearls were observed on this occasion progressively earlier at eastern stations. Fig. 2 shows a plot of the time of occurrence of pearl activity against (geographic) longitude. The graph is practically linear, the onset

Table 1

Station	Geographic Latitude	Geographic Longitude	Geomagnetic Latitude	Geomagnetic Longitude
Resolute Bay (Canada)	N.74°41′	W.94°55′	N 82.9°	289.3°
Reykjavik (Iceland)	N 64°11′	W.21°42′	N.70.2°	71 0°
Uppsala (Sweden)	N 59°58′	E.17°39′	N 58.7°	104 5°
Suffield (Canada)	N 50°15′	W.111°10′	N 57.3°	306.4°
Abbotsford (Canada)	N.49°03′	W.122°17′	N.54.6°	293 6°
Victoria (Canada)	N.48°25′	W.123°22′	N.54 1°	292.6°
Memambetsu (Japan)	N.43°55′	E.144°12′	N.34.1°	208.3°
Ruth (U S.A.)	N.39°16′	W 114°59′	N.46.4°	305.3°
Isabella (U.S.A.)	N 35°40′	W.118°28′	N.42.6°	303.1°
Huancayo (Peru)	S.12°03′	W.75°20′	S.0.6°	353.8°

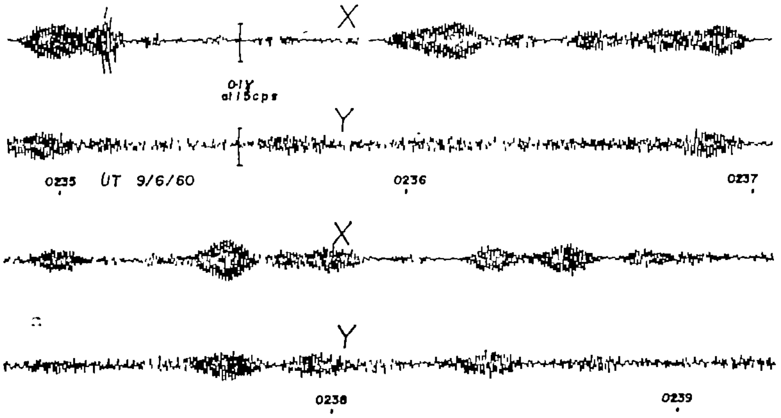

Fig. 1. Records of X and Y, Abbotsford, June 9, 1960, filtered.

of these pulsations moving westward at an approximate rate of 14°/hr. An even better linear fit is obtained if the time of onset is plotted against geomagnetic longitude.

To investigate further the L.M.T. or U.T. dependence of the onset of pearls, the records at Victoria, British Columbia, were examined for all cases of pearl activity from October 1960 until February 1961. The corresponding records for the times of occurrence were obtained from Benioff for Isabella, Ruth, Huancayo, Reykjavik, Resolute Bay and Uppsala. There is not sufficient difference in longitude between Isabella, Ruth and Victoria satisfactorily to resolve the question of local time dependence. In most cases pearl activity at these three stations was reported about the same time. At Resolute Bay it was impossible to recognize any pearl activity. However, the field is usually quite disturbed at that latitude and the sensitivity of the recording equipment was thus reduced so that many examples of pearls may have been missed. For the same reason, little pearl activity could be identified on the records from Reykjavik. At Huancayo the record is invariably quiet with an occasional burst of pearl (?) activity lasting for not more than 1 min. Such bursts have periods of about 2 sec., show some damping in amplitude and little or no correlation with records from other stations. The records from Uppsala, on the other hand, often showed pearls about 9 hr. earlier than their onset on the west coast of North America—in agreement with the linear trend of Fig. 2.

The magnetic observatory at Memambetsu (Japan) began rapid run recordings of Earth currents in December 1960 and the records for the first three months of operation were compared with the data from Victoria and Isabella. Only one out of eight occurrences of pearls at Memambetsu was also observed at Victoria and Isabella, although on this occasion the results were extremely interesting. Pearls were observed at Isabella about 6–7 hr. before their onset at Memambetsu and than again at Isabella some 17–18 hr. after their appearance at Memambetsu. The linear trend of Fig. 2 was thus extended right round the world on this occasion and is shown in Fig. 3, which also shows the double occurrence at Uppsala on consecutive days. The gradient of the line in Fig. 3 is 15°/hr.

The most obvious explanation of these results is that the onset of pearls depends entirely on local time. It is also possible that the graph expresses the azimuthal drift of charged particles trapped in the geomagnetic field. For a proton travelling at $1 \cdot 5 \times 10^6$ m./sec. (the velocity V of the solar wind under disturbed conditions), the azimuthal drift is about 17°/hr. The day in question, however, was not particularly disturbed, and a value of V for quiet solar conditions would reduce this figure by a factor of 10. Moreover, if pearls are due to the drift of protons trapped in the Earth's magnetic field, one would expect to observe the phenomenon with the frequency of the mirror oscillations, which is about 50 times too large for that of pearls, even under disturbed conditions.

The comparative rarity of pearls indicates that the ionosphere is an opaque shield for waves of this frequency most of the time. It is possible, of course, that pearls are more frequent but that their amplitude is in general below the threshold of the detecting equipment. In middle latitudes pearls are recorded mainly at sunrise and sunset and to a lesser extent during the night, and usually under geomagnetic quiet conditions. This tendency may be different in equatorial and polar regions. Troitskaya[3] has found that pearls are more frequent in polar regions and may occur at any time.

The results shown in Figs. 2 and 3 and the consistent time difference of occurrence between Uppsala and Victoria would indicate that, in these latitudes at any rate, pearls are L.M.T. dependent. The conditions which make the ionosphere transparent to

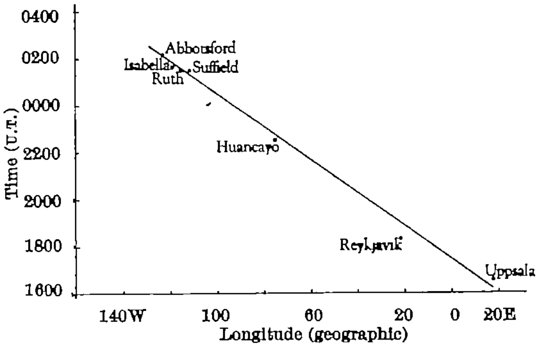

Fig. 2 Onset of pearl activity, June 8–9, 1960.

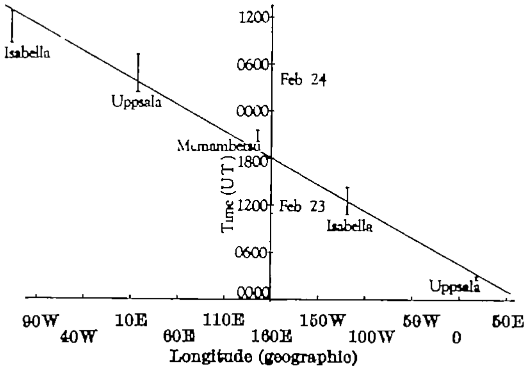

Fig. 3. Pearl activity, February 23–24, 1961

waves of pearl frequency are not clearly understood. In particular, the duration of suitable conditions is of interest—it is only very rarely that they exist for more than one rotation of the Earth, although pearls often occur on consecutive days. From the limited amount of data so far analysed, pearls were often observed at Victoria some 9 hr. after their appearance at Uppsala (longitude of separation 141°), but only once were they observed at Memambetsu after their appearance at Victoria (longitude of separation 92°). There were, however, many cases of their appearance at Memambetsu and their non-appearance at Victoria (longitude of separation 268° if their onset moves westwards). There is only 4° difference between the geomagnetic latitudes of Victoria and Uppsala, whereas Memambetsu is 20° to the south of Victoria and may thus reflect different conditions at low-middle latitudes.

No relationship was found between the occurrence of pearls and other ionospheric phenomena. Pearls usually occur about sunrise or sunset—the time of rapid change of f_0F_2. However, these changes in f_0F_2 take place daily, although more pronounced in winter, whereas pearls are comparatively rare. If the source is solar radiation, then a seasonal effect should be observed and their duration should be determined by solar conditions. There should also be a correlation with other phenomena in the ionosphere, which as yet has not been found. Moreover, any electromagnetic radiation effects would be propagated to the Earth in a few minutes, yet pearls are almost never observed during the daytime. If the source is corpuscular, either by direct injection or from the Van Allen radiation belts, no seasonal effects should be observed. Further analysis covering a longer period is desirable—particularly any results from conjugate points.

RADIOACTIVE AIR-BORNE DUSTS IN JAPAN

By T. MAMURO, A. FUJITA, T. MATSUNAMI, K. YOSHIKAWA and T. AZUMA

Radiation Centre of Osaka Prefecture, Shinkecho, Sakai, Osaka

AFTER the re-opening of the nuclear test explosions by U.S.S.R., during September 1961, fresh nuclear debris was found in ground-level air for the first time on September 12 at our Laboratory. Since then, the concentration of artificial radioactivity in the atmosphere has risen and has kept changing up and down by the successive explosions depending on meteorological conditions. On November 7, 8 and 9, abnormally high concentrations were observed, which ranged from 70 to 125 $\mu\mu$c./m.^{3}. These were considered to be due to the large-scale test explosion of 50 megaton hydrogen bomb carried out on October 30.

Towards the end of September it was generally recognized in Japan that the measured values of radioactive concentration in rain-water differed sometimes appreciably from each other, even though they were obtained at nearby laboratories at the same time. In order to investigate this, we took the autoradiographs of the air-borne dusts collected on large filter papers. It was concluded that such a situation was caused by the presence of a small number of highly radioactive particles in fall-out[1-3,6]. Air-borne dusts were collected on a circular filter paper 18·5 cm. in diameter at the

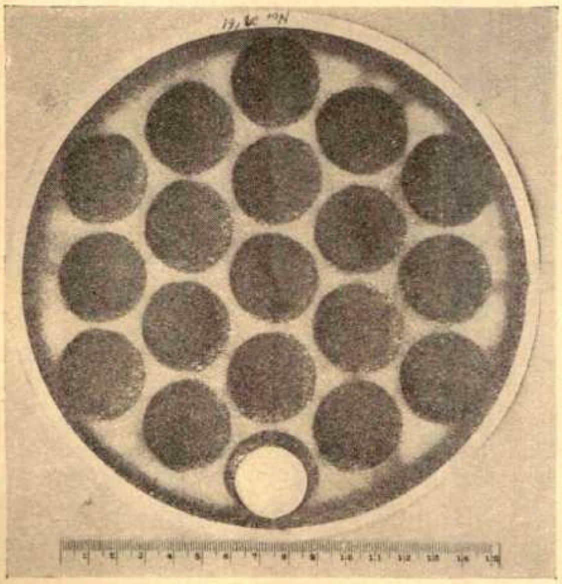

Fig. 1

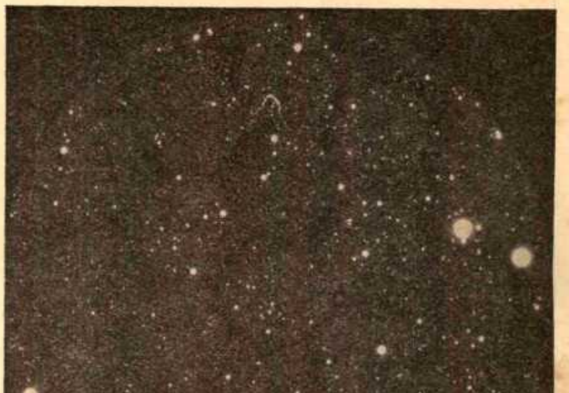

Fig. 2

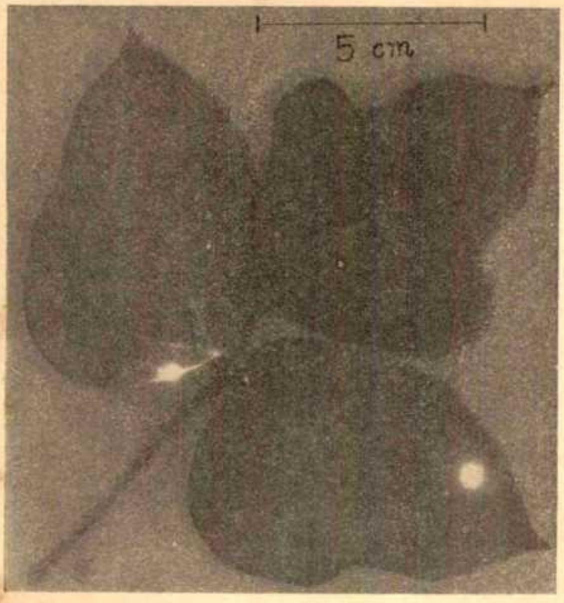

Fig. 3

suction rate of 400 l./min. Fig. 1 shows a filter paper dust sample on which the dusts have been collecting for 24 hr. A small circular area of 25 mm. in diameter was cut off from the filter paper and used as the sample for measuring the activity by a Geiger–Müller counter. Fig. 2 shows the autoradiograph of the dust specimen collected on November 7 by sampling 627 $m.^3$ of air. This was autoradiographed on an X-ray film (Fuji X-ray Film No. 200) for 16 hr. on November 14, one week after the sampling. The activity of the highly radioactive particle which produced the largest spot on this autoradiograph was about 20 mμc. just after sampling.

In order to examine how these highly radioactive particles became attached to the surface of vegetation, autoradiographs of the leaves of wild arrowroot were taken on November 13. About 12 sample leaves were collected at random in the yard of our Laboratory. Fig. 3 is the autoradiograph of one of them. The contour of the leaf was disclosed by irradiation of weak light after autoradiographic exposure in order to find out where the radioactive particles were located on the leaf. On careful inspection of the autoradiograph, it was seen that the blackening took place along veins in the vicinity of a large spot. It was therefore concluded that up-take of the radioactive substances took place through the leaf surface[5].

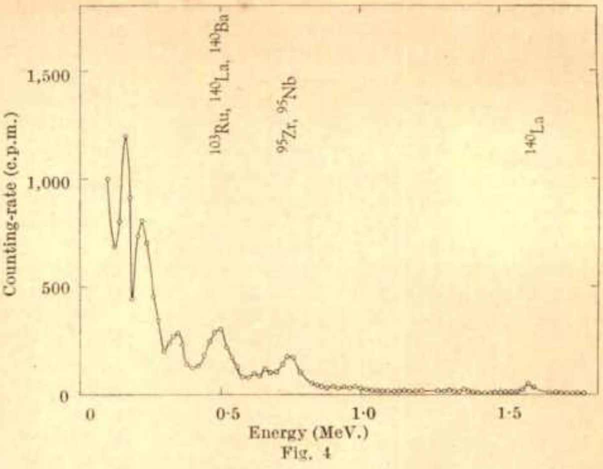

Fig. 4

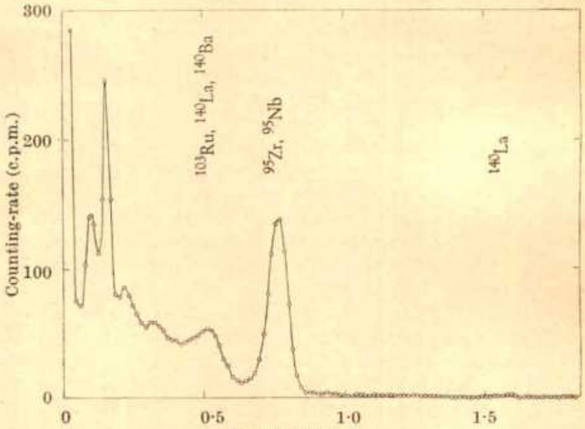

Fig. 5

A γ-ray spectrum of the dust sample collected on November 8 was taken on November 15 and is shown in Fig. 4. A highly radioactive particle was found on the surface of a polyethylene bottle which was left outdoors. Fig. 5 shows the γ-ray spectrum of this particle. The difference of distribution curves seen in Figs. 4 and 5 is considered to come from the so-called chemical fractionation effect[2,4].

ROCK MAGNETISM AND LOW-ANGLE FAULTING

THE recent article by Norris and Black[1] greatly extends the scope of rock magnetism studies by dealing with the Lewis thrust-sheet, a famous North American example of low-angle faulting with large displacement. From the point of view of palæomagnetism, this type of structure has always been considered unsuitable, because of the desire to select rocks with a remanent magnetization that could be presumed to have suffered no alteration since the rock was formed. The well-known deductions about polar wandering, continental drift, rotation of continents, etc., are wholly dependent on whether this concept of fossil magnetism is valid. Its validity is generally assumed to hold good, even for tilted formations, so long as the rock has not been subjected to metamorphic or gross tectonic effects.

The Lewis thrust-sheet is one of many large sheets situated on the eastern side of the Rocky Mountains.

Advancing on a 200-mile front, the Lewis sheet appears to have been displaced by up to 40 miles or more[2], with the remarkable stratigraphic result that rocks of Pre-Cambrian age are now widely superimposed on Cretaceous sediments. Can it be assumed that such a large-scale dislocation would occur without disturbing the direction of remanent magnetization in the transported rocks ?

This question can scarcely be answered on general grounds while the mode of formation of thrust-sheets is itself in doubt. The earlier picture of thrust-sheets as rigid plates pushed from behind is now recognized as mechanically unsound. Gravity gliding has been suggested as a possible alternative[3], but this requires a co-extensive basal surface of highly regular dip, and suitably lubricated. There is also the problem of how the sheet came to be formed in the first place. Here it should be noted that a low-angle fault does not necessarily coincide with any particular stratigraphic horizon. The Lewis fault, for example, has cut across pre-existing folds[2].

Many thrust-sheets (the Lewis among them) have retained a coherence that is hard to reconcile with the concept of rock as a rigid, brittle substance. Nevin[4] remarks: "the fact that sheets of rock have been displaced a distance much greater than their thickness, without complete shattering, is astonishing". A high degree of coherence in the Lewis sheet is confirmed by the remanence observations of Norris and Black, who have collected 59 samples from three different localities and obtained remarkably consistent directions of magnetization.

It would not be difficult to imagine ice-sheets similar in form to these great sheets of rock. Indeed, the characteristics of thrust-sheets are very much what one might expect if the rocks involved could be regarded as having significant plastic properties. A variety of other geological phenomena likewise suggest that on the geological time-scale all near-surface rocks behave plastically[5]. On this hypothesis thrust-sheets are seen as flow-sheets, generated perhaps by extrusion from the base of young mountains which by this means will tend to subside under gravity towards a state of plastic equilibrium.

Since plastic flow involves shear distortion it might be expected to alter the direction of any vector embedded in the rock, including the remanence vector. The plastic subsidence of tall objects has been briefly described by Orowan[6]; but no detailed analysis is available. In a well-developed thrust-sheet, however, the predominant effects are likely to be those that characterize flow in sheet-like bodies, and this has been extensively studied by glaciologists. In the present context the important feature of such flow is that the speed of movement is greatest at the top of the sheet and diminishes steadily downwards. This has been verified by direct observations on glaciers and also accounted for theoretically[7]. If the remanence vector rotates accordingly, the direction in which the sheet has flowed can be ascertained from the change in the direction of magnetization.

This relationship has been invoked recently in an attempt to reinterpret observations of remanence in western Europe as evidence of continental expansion[8]. Adopting a minimum of assumptions, it is postulated that throughout geological history the geomagnetic field has always approximated to that of a geocentric dipole aligned with the present geographical axis, and that discrepancies indicated by rock magnetism are due to plastic flow in the rock since it became magnetized, rather than to continental drift, etc.

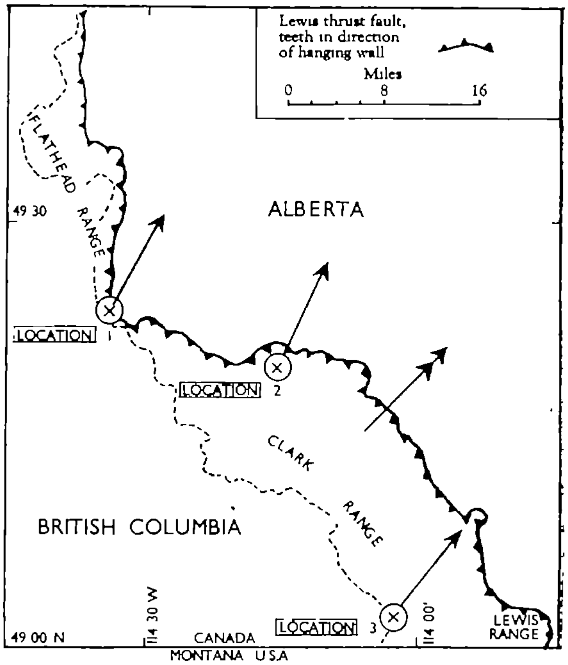

Fig. 1. Direction of movement of Lewis thrust-sheet, Rocky Mountains, Canada. Double arrow is based on geological evidence, single arrows on remanent magnetization. (Map details after Norris and Black (ref. 1).)

Thus the original inclination I_0 of the remanence vector is given by:

$$\tan I_0 = 2 \tan \lambda$$

where λ is the geographical latitude of the sampling locality. The azimuth θ in which the flow has occurred can be represented by:

$$\theta = \tan^{-1}\{\sin D/(\cos D - \tan I/\tan I_0)\}$$

where the remanence vector in its final position has inclination I and declination D. Since the direction of movement of the Lewis thrust-sheet is approximately known, whatever the mechanism might be, the above formula for θ provides some check on whether the plastic flow mechanism is plausible.

The Pre-Cambrian sandstone studied by Norris and Black was sampled at three sites near latitude 49° N. ($\lambda = 49°$), one of them situated near the middle of the Clark Range salient and one near each end. The number of samples and the mean values of declination and inclination measured for each site are listed in Table 1. The computed azimuths of flow (θ) are also given in Table 1, and are shown by means of arrows in Fig. 1, which has been prepared from the map of Norris and Black[1].

Table 1

Location	No. of samples	D	I	θ
1	27	218 5	39 5	29
2	24	213 0	49·0	26
3	8	230 0	38 0	38

All angles in degrees.

On geological evidence the direction of displacement of the Clark Range salient, according to Price[2], is north-eastwards. This direction (shown in Fig. 1 as a double arrow) is close to the directions of flow that have been inferred from the remanence data. It should be mentioned that the equation for θ has essentially only one meaningful solution[8]; there is no ambiguity here such as characterizes the determination of pole position in palæomagnetic studies.

It appears that the hypothesis that low-angle faulting is brought about by plastic flow in the overlying sheet[5], and that the direction of remanent magnetization is altered in the flow process, gains in plausibility from the example of the Lewis thrust-sheet. Further investigation may therefore be warranted along the following lines. Observations of magnetic remanence in other thrust-sheets for which the direction of movement is known would provide further opportunities to test the flow hypothesis. Secondly, the Lewis thrust-sheet might be examined for evidence of plastic deformation. Stress differences as small as 10^6 dynes/cm.^{2}, operating through geological time, may be capable of producing such deformation, the microscopic effects of which may thus be entirely different from those of the large stress differences usually contemplated in geology. The angle of "magnetic shear" indicated by the results of Norris and Black is about 55°; the angle of mechanical shear may be much smaller[8].

Norris and Black have interpreted their remanence observations in the standard palæomagnetic fashion. They mention that their calculated pole positions agree well with other results, as yet unpublished, for the late Pre-Cambrian of North America. In view of the entirely different interpretation suggested above, these further results will be awaited with interest.

[8] Evison, F. F., *Geophysical J.*, 4, 320 (1961).

WE are interested in Dr. Evison's application of our basic palæomagnetic data[1] to the mechanics of emplacement of the Lewis thrust-plate in the south-eastern Cordillera of Canada. He questions whether the ancient remanence vectors could have been effectively preserved in the plate in view of the possibility that it may have undergone plastic flow.

It is our view that the rocks of the Lewis thrust-plate did not undergo significant plastic flow and that the remanence vectors maintained a common Pre-Cambrian pole position before, during and after the movement history of the plate.

That there has been deformation beyond the elastic limit within the plate is without question, but the geology of the plate offers little to support the contention that it reached its present position as a flow-sheet. As will be mentioned briefly, geological mapping confirms that displacement of the Lewis thrust-sheet was accomplished through relative motion on a shear surface or zone. Deformation within the sheet was limited almost exclusively to thrust faulting, folding and interbed slip.

The Lewis thrust is made up of a series of glide surfaces or zones parallel or sub-parallel to the layering with interconnecting shoulders or steeper portions where the thrust cuts through the stratigraphic succession either along or across the strike. It either selectively parallels specific zones[3] or, with local exception, cuts up section in the direction of relative displacement of the thrust plate. From surface and well data in the area studied it is known to parallel a zone a few hundred feet below the top of the Pre-Cambrian Waterton Formation for an area in excess of 500 square miles. Only locally does it truncate folds[3].

Except in the immediate vicinity of the thrust surface, movement within the Lewis thrust-plate consisted primarily of displacement on significantly few fault splays and of development of broad, open folds[3]. Of secondary importance was differential forward movement within the mass accomplished by interbed slip as well as by shear deformation in incompetent units.

The fact that this differential shearing motion was limited to bedding surfaces and to incompetent units is demonstrated by the remarkable preservation of even the most delicate primary structures, of both organic and sedimentary origin in the competent rocks making up the plate[4,5]. So obvious is this phenomenon that early geologists mistook these Pre-Cambrian rocks to be as young as Cambrian to Triassic[6].

The competent rocks from which our oriented samples were collected showed no signs of fracture cleavage or flow. Oolites and stromatolites from competent Pre-Cambrian rocks slightly lower in the plate do not appear to be deformed in such a manner as might be anticipated if shearing deformation were pervasive through the rock. We have observed moreover that pre-Laramide joints are statistically perpendicular to bedding, deviations being to one side or other, and showing no indication whatsoever that blocks outlined by joints have been deformed by simple shear.

It is unlikely therefore that the mechanism of transport of the Lewis thrust-plate could have been one of pervasive plastic flow as outlined by Dr. Evison. Macroscopically, movement was along well-defined fault surfaces. Microscopically, any plastic flow that may have occurred was so insignificant that the primary fabric of the rock was left unaltered except for local shear zones.

The logical deduction that the remanence vectors in these Pre-Cambrian rocks have not been significantly altered by plastic flow at the scale of the 1-in. cubes studied by us is confirmed moreover by a comparison of our pole positions from rocks in the plate with pole positions for undisturbed rocks of comparable age in North America[7].

It is therefore concluded with reasonable certainty that the orientation of the remanence vectors has not been significantly altered as a consequence of the tectonic history of the Lewis thrust-plate and that the plate was transported as a coherent but flexible mass and not as an extruded flow sheet.

FIVE-DIMENSIONAL COSMOLOGY AND THE HYPOTHESIS OF NEGATIVELY CHARGED STARS

PROF. V. A. BAILEY[1] has shown that many astronomical phenomena can be explained by the hypothesis that a star, such as the Sun, carries a net negative charge. He suggests (hypothesis H_2) that such a charge could arise if the universe were five dimensional, and that the laws of conservation hold exactly, not in the four-dimensional continuum of space-time, but in the more fundamental five-dimensional continuum. Accordingly, an investigation was made into a statement of the conservation laws for the five-dimensional model used in the unified field theory of Kaluza and Klein[2,3].

The first fundamental form for the five-dimensional continuum is taken as:

$$d\sigma^2 = \gamma_{\mu\nu}\, d\xi^\mu\, d\xi^\nu. \qquad (\mu, \nu = 1, 2, 3, 4, 5)$$

A unit vector field A^μ is postulated, by means of which a four-dimensional Riemannian space:

$$ds^2 = g_{ab}\, dx^a\, dx^b. \qquad (a, b = 1, 2, 3, 4)$$

is constructed. A special system of co-ordinates, ξ^μ, is chosen for which $\xi^a = x^a$, and the $\gamma_{\mu\nu}$ are taken to be independent of ξ^5. This latter, the A-cylindrical condition, prevents difficulties with the unfamiliar ξ^5 co-ordinate in the physical equations. As yet, it will not be assumed that γ_{55} is constant. A skew-symmetrical tensor, f_{ab}, also is introduced by means of this material.

The geodesic equations in five dimensions:

$$\frac{\delta}{\delta\sigma}\left(\frac{d\xi^\mu}{d\sigma}\right) = 0$$

where δ denotes intrinsic differentiation, give the set of four equations:

$$\frac{\delta}{\delta s}\left(m_0 \frac{dx^a}{ds}\right) + \frac{e}{c^2} f^a{}_b \frac{dx^b}{ds} + \frac{1}{2} \frac{e^2}{m_0 c^4} g^{ab}\left(\frac{1}{\gamma_{55}}\right)_{,\,b} = 0 \qquad (1)$$

together with:

$$\frac{de}{ds} = 0 \qquad (2)$$

where m_0 and e are scalars in the four-dimensional space. The $,\,b$ denotes ordinary partial differentiation with respect to x^b.

If γ_{55} is constant, (1) takes exactly the form of the equations governing the motion of a charged particle in ordinary general relativity, and (2) expresses the conservation of e.

The natural five-dimensional generalization of the equations of motion and conservation for a continuous medium is:

$$J^{\mu\nu}{}_{;\,\nu} = 0$$

where $J^{\mu\nu}$ has the form:

$$\rho \frac{d\xi^\mu}{d\sigma} \frac{d\xi^\nu}{d\sigma} + \tilde{\omega}\gamma^{\mu\nu}$$

and ; denotes covariant differentiation in five dimensions. This leads to the four equations:

$$\left(r \frac{dx^a}{ds} \frac{dx^b}{ds} + p g^{ab}\right)_{:\,b} - \varepsilon_1 f^a{}_b \frac{dx^b}{ds} - g^{ab}\,(\sqrt{\gamma_{55}})_{,b} \left(\frac{\varepsilon_1{}^2}{r\gamma_{55}{}^{3/2}} + \frac{p}{\sqrt{\gamma_{55}}}\right) = 0 \qquad (3)$$

together with:

$$\left(\varepsilon_1 \frac{dx^b}{ds}\right)_{:\,b} = 0 \qquad (4)$$

where : denotes covariant differentiation in the four-dimensional space, and r, ε_1 and p are scalars in this space related to ρ and $\tilde{\omega}$. When γ_{55} is constant, (3) resembles the ordinary relativistic hydrodynamical equations governing the motion of a charged medium in an electromagnetic and a gravitational field. (4) corresponds to the equation of conservation of charge.

In (1) and (2), the 'charge' e is related to the 'mass' m_0 by:

$$e = m_0 c^2 \sqrt{\gamma_{55}}\, A_\mu \frac{d\xi^\mu}{ds}$$

Corresponding to this, we should expect the 'charge density' ε to be related to the 'mass density' r_0 by:

$$\varepsilon = r_0 c^2 \sqrt{\gamma_{55}}\, A_\mu \frac{d\xi^\mu}{ds} \qquad (5)$$

Now, in ordinary four-dimensional relativity, the energy-momentum density tensor in terms of the rest density r_0 and pressure p_0 is:

$$T^{ab} = -(r_0 c^2 + p_0) \frac{dx^a}{ds} \frac{dx^b}{ds} + p_0 g^{ab}$$

Referring to (3), it is seen that the scalar r introduced there is given in terms of density r_0 by:

$$r = -(r_0 c^2 + p_0)$$

while:

$$p = p_0$$

But the ε_1 in (3) and (4) is found to be given by:

$$\varepsilon_1 = -r \sqrt{\gamma_{55}}\, A_\mu \frac{d\xi^\mu}{ds}$$

So, in terms of ordinary density, this is:

$$\varepsilon_1 = (r_0 c^2 + p_0) \sqrt{\gamma_{55}}\, A_\mu \frac{d\xi^\mu}{ds}$$

Comparing this with (5):

$$\varepsilon_1/\varepsilon = 1 + \frac{p_0}{r_0 c^2}$$

ε_1 plays the part of charge density of the medium, regarded as continuous. (4) expresses the conservation of this charge. ε is the charge density of the medium, regarded as a distribution of discrete, unconnected particles, each having a constant charge.

These cannot both be the true charge. It is natural to assume that ε, the one depending on the discrete particles, is the true charge, because of the fundamental nature of such charged particles as the electron. The equation (4) then shows that this true charge is not conserved in a moving medium in which the pressure and density are variable. In terms of true charge density, (3) and (4) are, for the case where γ_{55} is constant:

$$\left\{-(r_0 c^2 + p_0) \frac{dx^a}{ds} \frac{dx^b}{ds} + p_0 g^{ab}\right\}_{:\,b} - \varepsilon\left(1 + \frac{p_0}{r_0 c^2}\right) f^a{}_b \frac{dx^b}{ds} = 0$$

$$\left\{\varepsilon\left(1 + \frac{p_0}{r_0 c^2}\right)\frac{dx^b}{ds}\right\}_{:\,b} = 0$$

where r_0 is the actual rest density, p_0 the pressure, and ε the charge density. From a macroscopic point of view, if a given portion of the material is transported from place to place, the charge it contains varies as $1\Big/\left(1 + \frac{p_0}{r_0 c^2}\right)$.

Thus, it appears that conservation in five dimensions implies that there is not conservation in the four-dimensional space, in general.

It might be expected that gravitational forces would tend to cause a settling of the heavier, positively charged, particles towards the centre of the Sun against the effects of the electric forces and thermal motions. Since it is likely that $1\Big/\left(1 + \frac{p_0}{r_0 c^2}\right)$ will decrease towards the region of greater pressure, this will cause a net negative charge on the Sun, as required by Bailey's hypothesis, and apparently confirmed by the interplanetary magnetic measurements recorded by the solar satellite *Pioneer V* (ref. 4).

As well as giving equations which closely resemble those of ordinary relativity, choosing γ_{55} constant is satisfactory also from a theoretical point of view, since the A-cylindrical condition can then be expressed simply in a manner covariant for all the corresponding systems. However, suppose now that γ_{55} is not constant, and consider the case of a particle momentarily at rest with respect to a geodesic Lorentz co-ordinate system. The time component of equation (1) is:

$$\frac{\mathrm{d}m_0}{\mathrm{d}t} = -\tfrac{1}{2}\frac{e^2}{m_0 c^4}\frac{\partial}{\partial t}\left(\frac{1}{\gamma_{55}}\right)$$

Thus it appears that the γ_{55} term can destroy the conservation of rest mass. The use of co-ordinate systems which are not special could introduce additional terms having the same effect. Bailey[5] has suggested that expanding models of the universe which depend on the continual creation of matter might be consistent with the postulate of conservation in the five-dimensional space. The above result indicates that this may be so, but whether the expanding universe of constant density described by Hoyle[6] can be obtained as a by-product of the five-dimensional theory depends on the discovery of suitable field equations.

Mathematical appendix. An outline of the derivation of the equations (1)–(4) is given here. The description of the theory follows that of Bergmann[3] to a large extent.

In the space of the five-dimensional co-ordinate system, ξ^μ, four parameters, $x^s \equiv x^s(\xi^\mu)$, are chosen. Greek suffixes range from 1 to 5, and Latin suffixes from 1 to 4. Let:

$$\gamma^{a}_{\alpha} = x^{a}{}_{,\alpha} \equiv \partial x^{a}/\partial \xi^{\alpha} \qquad \text{(i)}$$

Then the field A^α is defined by:

$$\begin{cases} \gamma_{\alpha} A^{\alpha} = 0 & \text{(ii)} \\ A^{\alpha} A_{\alpha} = 1 & \text{(iii)} \end{cases}$$

The reciprocal γ^{α}_{a} are defined by:

$$\begin{cases} \gamma^{a}_{\alpha}\gamma^{\alpha}_{b} = \delta^{a}_{b} & \text{(iv)} \\ \gamma^{\alpha}_{a} A_{\alpha} = 0 & \text{(v)} \end{cases}$$

The fields g_{ab} and φ_{ab} are then taken to be:

$$g_{ab} = \gamma^{\alpha}_{a}\gamma^{\beta}_{b}\gamma_{\alpha\beta} \qquad \text{(vi)}$$

$$\varphi_{ab} = \gamma^{\alpha}_{a}\gamma^{\beta}_{b} A_{\alpha\beta} \qquad \text{(vii)}$$

where:

$$A_{\alpha\beta} = A_{\alpha,\beta} - A_{\beta,\alpha} \qquad \text{(viii)}$$

The equations (ii)–(v) lead to:

$$\gamma^{\alpha}_{a}\gamma^{a}_{\beta} = \delta^{\alpha}_{\beta} - A^{\alpha} A_{\beta}$$

giving, with (vi):

$$\gamma_{\mu\nu} = g_{ab}\gamma^{a}_{\mu}\gamma^{b}_{\nu} + A_{\mu} A_{\nu} \qquad \text{(ix)}$$

and:

$$\gamma^{\mu\nu} = g^{ab}\gamma^{\mu}_{a}\gamma^{\nu}_{b} + A^{\mu} A^{\nu} \qquad \text{(x)}$$

where:

$$g^{as}g_{bs} = \delta^{a}_{b}$$

For the special system in which:

$$\xi^{s} = x^{s} \qquad \text{(xi)}$$

(i) gives:

$$\gamma^{a}_{\alpha} \equiv \begin{pmatrix} \gamma^{a}_{b} \\ \gamma^{a}_{5} \end{pmatrix} = \begin{pmatrix} \delta^{a}_{b} \\ 0 \end{pmatrix}$$

and so, from (ii) and (iii):

$$A^{\alpha} = (0,0,0,0,\ 1/\sqrt{\gamma_{55}})$$

Hence.

$$A_{\alpha} = \gamma_{5\alpha}/\sqrt{\gamma_{55}} \qquad \text{(xii)}$$

Writing this as:

$$A_{\alpha} = \sqrt{\gamma_{55}}\,(\varphi_{a},\ 1) \qquad \text{(xiii)}$$

(iv) and (v) are solved to give:

$$\gamma^{\alpha}_{a} \equiv \left(\gamma^{b}_{a},\ \gamma^{5}_{a}\right) = \left(\delta^{b}_{a},\ -\varphi_{a}\right)$$

Thus, from (ix):

$$\gamma_{\alpha\beta} = \begin{pmatrix} g_{ab} + \gamma_{55}\varphi_a\varphi_b, & \gamma_{55}\varphi_a \\ \gamma_{55}\varphi_b, & \gamma_{55} \end{pmatrix} \qquad \text{(xiv)}$$

and (x):

$$\gamma^{\alpha\beta} = \begin{pmatrix} g^{ab}, & -g^{as}\varphi_s \\ -g^{bs}\varphi_s, & \gamma_{55}{}^{-1} + g^{rs}\varphi_r\varphi_s \end{pmatrix}$$

The A-cylindrical condition:

$$\gamma_{\alpha\beta,5} = 0 \qquad \text{(xv)}$$

gives, from (xii):

$$A_{\alpha,5} = 0$$

from (xiii):

$$\varphi_{a,5} = 0$$

and from (xiv):

$$g_{ab,5} = 0$$

Since the field equations must be a generalization of those of ordinary relativity, the tensor $J^{\alpha\beta}$ must depend on $\gamma^{\alpha\beta}$, and so, even though the field equations might not be determined as yet, it is possible to say, from (xv), that:

$$J^{\alpha\beta}{}_{,5} = 0$$

From (vii) and (viii):

$$\varphi_{ab} = \sqrt{\gamma_{55}}(\varphi_{a,b} - \varphi_{b,a})$$

By (xi), the , a denotes partial differentiation with respect to x^a as well as ξ^a for those functions which, through the A-cylindrical condition, are independent of ξ^5. The array:

$$f_{ab} = \varphi_{ab}/\sqrt{\gamma_{55}}$$

therefore is derivable from a four-vector potential in the same way as the electromagnetic field tensor in ordinary relativity, and so satisfies part of Maxwell's equations.

Using the above formulæ, the components of the five-dimensional Christoffel symbols can be evaluated in terms of those in the four-dimensional space. It is found that:

$$\left\{ \genfrac{}{}{0pt}{}{s}{\alpha\beta} \right\}_{(5)} = \gamma^a_\alpha \gamma^b_\beta \left\{ \genfrac{}{}{0pt}{}{s}{ab} \right\}_{(4)} + \tfrac{1}{2} g^{sr} \gamma^\rho_r \left(A_\alpha A_{\rho\beta} + A_\beta A_{\rho\alpha}\right)$$

$$A_\mu \left\{ \genfrac{}{}{0pt}{}{\mu}{\alpha\beta} \right\}_{(5)} = \tfrac{1}{2}(A^\rho A_\alpha A_{\rho,\beta} + A^\rho A_\beta A_{\rho,\alpha} + A_{\alpha,\beta} + A_{\beta,\alpha})$$

$$\left\{ \genfrac{}{}{0pt}{}{\sigma}{\alpha\sigma} \right\}_{(5)} = \gamma^a_\alpha \left\{ \genfrac{}{}{0pt}{}{s}{as} \right\}_{(4)} + A^\sigma A_{\sigma,\alpha}$$

With these, operating on the geodesic equations.

$$\frac{\delta}{\delta\sigma}\left(\frac{d\xi^\mu}{d\sigma}\right) \equiv \frac{d^2\xi^\mu}{d\sigma^2} + \left\{ \genfrac{}{}{0pt}{}{\mu}{\alpha\beta} \right\}_{(5)} \frac{d\xi^\alpha}{d\sigma} \frac{d\xi^\beta}{d\sigma} = 0$$

with γ^a_μ gives (1), and operating with A_μ gives (2). In (1) and (2):

$$m_0 = \alpha \frac{ds}{d\sigma}, \alpha \text{ constant,}$$

and:

$$e = m_0 c^2 \sqrt{\gamma_{55}}\, A_\mu \frac{d\xi^\mu}{ds}$$

Operating on the equations of conservation:

$$J^{\mu\nu}{}_{;\nu} \equiv \left(\rho \frac{d\xi^\mu}{d\sigma} \frac{d\xi^\nu}{d\sigma} + \tilde{\omega}\gamma^{\mu\nu} \right)_{;\nu} = 0$$

with γ^a_μ gives (3), and operating with A_μ gives (4). In (3) and (4):

$$r = \sqrt{\gamma_{55}}\, \rho \left(\frac{ds}{d\sigma}\right)^2$$

$$p = \sqrt{\gamma_{55}}\, \tilde{\omega}$$

$$\varepsilon_1 = - r \sqrt{\gamma_{55}}\, A_\mu \frac{d\xi^\mu}{ds}$$

The suggestion that a five-dimensional model (U_5) of the Universe may be useful in cosmology[1] led quite naturally to the view that the laws of conservation of momentum, energy and electric charge are strictly true in such a universe U_5 and only approximately true in our space–time universe U_4.

This view led later to the conclusion that stars like the Sun carry large negative charges[2] and in this way provided a unified theory of several different astrophysical phenomena and also led to successful predictions concerning the interplanetary magnetic field measurements of the solar satellite *Pioneer V* [3].

These facts show that Dr. Taylor's quantitative discussion of five-dimensional cosmology is of distinct importance, for it not only confirms the view stated above but also is remarkable for its derivation of the empirically correct sign of the Sun's net charge[3].

It is to be hoped that in due course the correct field equations will be derived from the five-dimensional model. It is true that Kaluza has given an associated variational procedure[4] by means of which he derived Maxwell's electromagnetic field equations and Einstein's gravitational field equations; but this particular procedure probably yields only a first approximation for weak fields, for Einstein has pointed out that the existence of stable charged particles like electrons requires that the correct electromagnetic field equations be non-linear in the field variables. Guides to finding a correct procedure may perhaps exist in current non-linear field equations such as those due to Born, Infeld and Dirac[5].

It may be noted that Dr. Taylor's conclusion that the charge density ε varies inversely as the quantity $1 + p_0/r_0c^2$ leads also to the conclusion that the rate of apparent creation of net charge in interstellar space is small compared with the rate near and inside stars. This and the negative sign for the charge are conclusions which disagree with the hypotheses of Lyttleton and Bondi[6].

Lastly, it may be pointed out that additional direct observations of interplanetary magnetic fields, made by means of a pair of differently moving space vehicles in a relatively small region, would offer additional evidence on the hypothesis that the Sun carries a large negative charge and so perhaps offer evidence concerning the five-dimensional model of the Universe.

GROWTH OF ALLOPREGNANE SINGLE CRYSTALS

By Dr DORITA A. NORTON and LORENZO COSTA

Department of Biophysics, Roswell Park Memorial Institute, Buffalo, New York

PART of our programme of determining the molecular structures of steroids by X-ray crystallographic methods is the growth of good single crystals. For our purposes a good single crystal is one having the following characteristics: (1) a unique lattice orientation; (2) absence of strain; (3) absence of impurities; (4) a reasonably small number of vacancies and dislocations; (5) an ideally imperfect nature; (6) a diameter within the 0·2–1·0 mm. range; (7) well-defined external faces.

Recently, we have examined the crystallization properties of a group of allopregnanes. Considering the usual factors affecting the growth of single crystals from solution (degree of supersaturation, saturation velocity, temperature of crystallization, nature of the solvent, presence of impurities; presence of seeds, and agitation of the solution during crystallization), we have empirically recognized certain relationships between allopregnane polycrystalline aggregates and the conditions of crystallization. These relationships are of proved utility in establishing procedures which have resulted in the growth of good single crystals of the allopregnanes.

Good allopregnane crystals usually crystallize from solution only within a narrow range of conditions. Since these ideal conditions are different for each solvent–solute system, finding these conditions for any given system is sometimes difficult, and is always based on empirical techniques. Our observations of more than 300 crystallizations and crystallization products suggest that some features of allopregnane crystalline precipitates are often related to determinable and controllable conditions present during the process of crystallization. These features, therefore, may indicate the paths to be followed to obtain ideal conditions of crystallization, and good single crystals. The purpose of this article is to present our empirical findings on this subject.

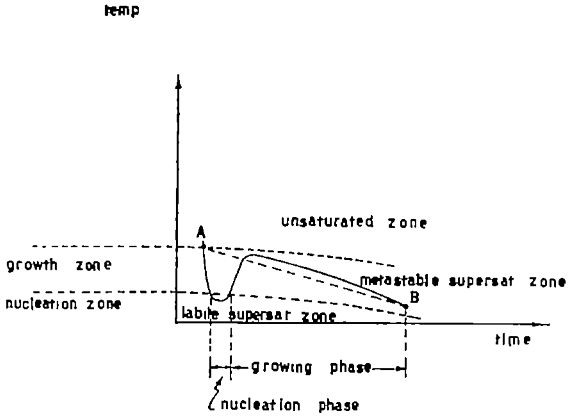

Fig. 1

In general, time–temperature plots of allopregnane saturated solutions prepared at elevated temperatures and cooled are divided into three zones (Fig. 1). These zones include an unsaturated zone, a metastable supersaturated or growth zone, and a labile supersaturated or nucleation zone. We have observed that if saturated allopregnane solutions are allowed to cool normally, that is, in a straight-line path either rapidly or slowly, many nuclei can form and polycrystalline aggregates (either in the form of spherulites or concretions) can result. Good single crystals have been obtained in many instances by altering the cooling path as indicated in Fig. 1. In this alteration, the cooling path is forced to dip briefly into the zone of nucleation, resulting in the production of a relatively small number of nuclei. The temperature is then raised to a point just below the upper boundary of the growth zone. Next, the solution is forced to cool along the indicated path, which usually yields good single crystals.

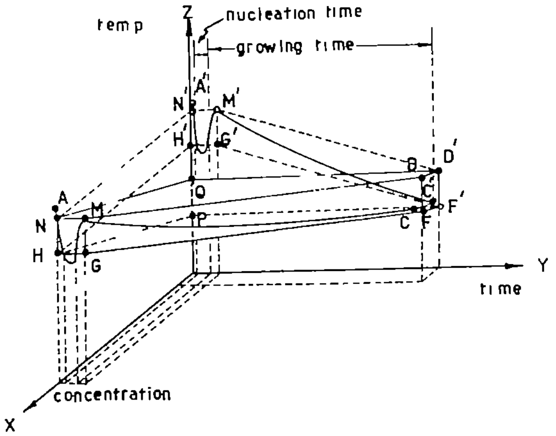

Fig. 2

Fig. 2 illustrates in more detail the process described above, namely, solute-phase crystallization across a large metastable supersaturated zone. Curve *AC* represents the general path which the solution must follow in order to yield single crystals as a product. Curve *A'C'* is the orthogonal projection of curve *AC* on the *yz*-plane (time and temperature). The surface *NMDFGH* is a cross-section of that portion of the metastable supersaturated zone within which the concentration, temperature, and time vary. The surface *N'M'D'F'G'H'* is the orthogonal projection on the *yz*-plane of the cross-section of the metastable supersaturated zone. Lengths *NN'* and *CC'* represent respectively initial and final concentrations of the solution. In three dimensions the metastable supersaturated zone is represented by a 'stratum' dipping in the direction of negative concentration. The surface *PQD'F'* is the cross-section of this zone by the *yz*-plane. In examining the temperature–concentration–time relationships of the cooling paths of any particular allopregnane, the upper and lower limits (lines *MD* amd *GF*, respectively) of the metastable supersaturated zone must be determined experimentally. By initially referring to a temperature time diagram (such as Fig. 1) and determining *M'D'* and *G'F'*, this operation can be facilitated.

When working with allopregnane solutions, which have been prepared at room temperature and allowed to evaporate to dryness, the following relationships appear to be valid:

(1) Concretions are due to a very high degree of supersaturation. Single crystals may be obtained by decreasing the amount of evaporation, decreasing the speed of evaporation, or supplying seeds (which allows crystal growth in the metastable zone).

(2) Allopregnane dendrites have two causes: (*a*) The time of crystallization is not long enough. Good crystals may be obtained by decreasing the speed of evaporation. (*b*) The temperature–concentration–time system has a large metastable supersaturated zone, which prohibits nucleation until the last stage of evaporation. The time remaining before dryness is not enough to yield crystallization. Single crystals may be produced by adding seeds during evaporation, or by inducing early nucleation by scratching, stirring, pouring, etc.

(3) We observed that whiskers result from the formation of a gel (also see Amelinckx[1]), hence single crystals may be formed by preventing the formation of a gel by stirring, adding traces of other solvents, and shortening the evaporation time. Whiskers

growing from single crystals indicate the presence of a 'poison' in the solution. A 'poison' is defined by Sears[2] as a small amount of soluble impurity in a solution which will appreciably alter the normal growth behaviour. This change may involve both the growth-rate of various crystal faces and the final crystal habit. The following techniques have been successfully used to obtain single crystals when impurities are present: (*a*) purification of the allopregnane or the solvent, or both; (*b*) beginning with more solution, halting evaporation as soon as the crystals reach the desired size, and pouring away the remaining solution.

(4) When only spherulites occur, crystallization takes place under conditions which we found impossible to control using the same solvent–solute system. Good crystals can sometimes be obtained by changing the solvent.

(5) When impurities reach a critical concentration in the last stage of evaporation, drusy surfaces result. Single crystals with non-drusy surfaces may be obtained by halting the process of crystallization before the last stage of evaporation is reached.

(6) Glassy-capped crystals result from the formation of a film during evaporation, and may be avoided by stirring or agitating the evaporating solution.

(7) Crystals with serrated edges generally occur when the crystal has emerged from the solution during evaporation. These may be avoided by starting with more solution and stopping the evaporation before dryness.

ANNUAL RHYTHM OF WOOL GROWTH

By J. W. BENNETT, J. C. D. HUTCHINSON and
MANIKA WODZICKA-TOMASZEWSKA

Ian Clunies Ross Animal Research Laboratory, Prospect,
New South Wales

THE influence of climate on the annual rhythm of wool growth has puzzled physiologists for many years. We have discussed the earlier literature elsewhere[1], and since our review Hart[2] has given more details of his work on the effects of day-length. Recently, Morris[3] reported experiments from which he concluded that the seasonal cycle is induced primarily by seasonal changes of day-length because reversing the photoperiodic seasons reversed the rhythm. He was unable to detect an effect of temperature. In our article we report such an influence on the rhythm and data on its persistent nature.

We took two groups of 14 adult ewes, half of them Southdowns and half medium-wool Merinos, which had been maintained indoors for 6 months in the normal indoor temperatures and day-lengths of Prospect, New South Wales (lat. 34° S.), except that the lighting was artificial. One group, called in this article the controls, was exposed to normal indoor temperatures and to exaggerated photoperiodic seasons of normal phase representing a latitude of 60° S. The experimental group was subjected to a régime of reversed and somewhat exaggerated thermal seasons and a constant equatorial day-length beginning September 17, 1958. Wool was gathered every 28 days by clipping two tattooed patches, each 10 × 10 cm. in area, of which one was on the mid-side and the other low on the thigh. The remainder of the fleece was kept at a fairly constant length by shearing to 1 cm. for the Southdowns and 1·5 cm. for the Merinos every 56 days. Three Southdowns and four Merinos in each group had an insulating cover strapped over the mid-side patch, comparable in thickness with the rest of the fleece. None of the thigh patches was covered. The ration fed was nearly constant for each animal and allowed a small increase in weight. One of the Southdowns, in the control group, died during the experiment.

The annual rhythm of the Merinos was very small, but in general gave the same responses to treatment which are shown for the Southdowns in Fig. 1. The rhythm of wool production of the controls was similar to that found by earlier workers[4]. In this group the seasonal variations for the three types of patch (covered mid-side, uncovered mid-side and thigh) were similar.

The covered mid-side patches of the experimental group showed a rhythm which was nearly the same as in the mid-side and thigh patches of the control group, except that the maxima were slightly delayed by about four weeks (Fig. 1*B*). Thus, when the day-length was constant, and the seasonal variations of temperature were reversed, a nearly normal annual rhythm persisted.

The maxima for the uncovered mid-side and the thigh patches were considerably delayed by about 12 weeks (Fig. 1*C*, *D*). The displacement of the minima for the thigh patches was about 5 months, but was variable for the uncovered mid-side, suggesting some topographical difference in the reactions to the experimental climate.

The phase shift in the rhythm of the thigh and uncovered mid-side patches of the experimental group indicates that temperature can influence the expression of the rhythm when there is little or no wool cover. This effect must be local, because a nearly normal rhythm of wool growth occurred beneath the insulating covers, while simultaneously a modified rhythm was shown on the uncovered thigh patches of the same animals. The phase shift appears to be an effect of cold because, as already mentioned, it was only shown to a marked degree on the uncovered patches.

In March and April covered patches in the experimental group produced much less wool than in December and January, despite the higher ambient temperature and, therefore, local temperature of the patch; it seems as though the wool follicles entered a refractory phase following a period of high wool production. In March and April the uncovered

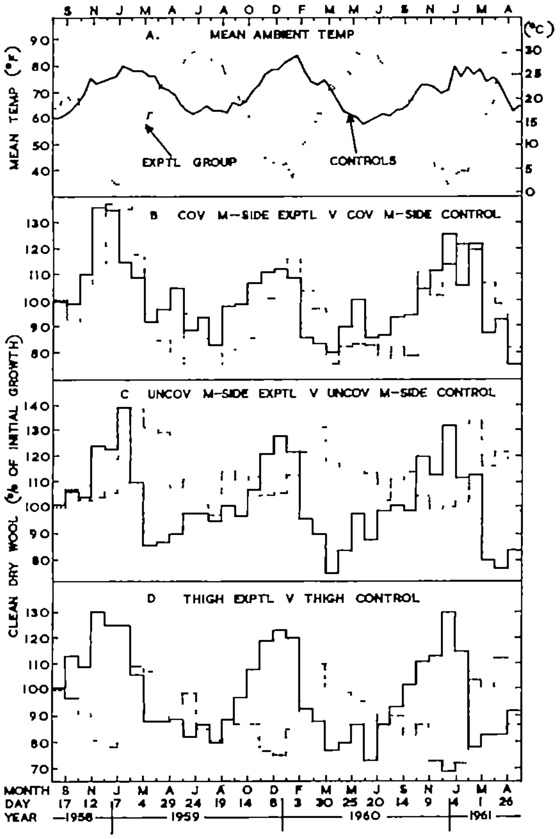

Fig. 1. Clean dry wool gathered from tattooed patches on the Southdown ewes, related to mean ambient temperature. Wool growth is expressed as a percentage of that over the 28 days preceding September 17, 1958, when the treatments started. When their mean ambient temperature exceeded 70° F., the experimental group had a diurnal rhythm of temperature with a minimum of 70° F., there was no diurnal rhythm over the rest of the year The controls had the natural indoor diurnal rhythm ... experimental group; —— control group, *M-side*, mid-side; *cov.* covored.

patches produced much more wool than the covered patches, although the local temperature must have been lower for these than for the covered patches. It would seem that the period of high production, delayed by the cold of December and January, could occur when temperature began to rise. Thus, temperature shifted the phase of the rhythm rather than causing an additive effect. It seemed to act like the various modifiers, which can influence the time of breeding of those species of birds the reproductive cycle of which is primarily controlled by day-length[5]. The fact that it was possible for sheep with covered mid-side patches to exhibit simultaneously two different rhythms raises the intriguing possibility that the rhythmicity may be to some degree controlled within the wool follicles themselves.

Our observation that the annual rhythm can be persistent provides a possible explanation of the long photoperiodic treatment that Morris found necessary to reverse the rhythm. Morris detected no effect of temperature on uncovered patches when he reversed the thermal seasons while maintaining exaggerated photoperiodic seasons of normal phase, but his winter temperatures may have been higher than ours (only mean monthly maxima were recorded). We, indeed, observed little effect of temperature in the warmer microclimate of the covered mid-side patches. It would be expected that wool growth in the fleeced sheep would be similar to that on our covered patches and, therefore, not easily influenced by ambient temperature.

We conclude that the annual rhythm of wool growth can in certain circumstances be modified by temperature. The modified rhythm can occur on one part of the skin, while on other parts (covered mid-side patch of the experimental group) an almost normal rhythm continues; the latter, like many circadian rhythms, can persist for a considerable time in the absence of the climatic stimuli which are presumed to have initiated it, and normally to maintain it. Our observations do not imply that the rhythm, once established, is independent of climate in the fleeced sheep. For the work of Hart and Morris and also our own and Wildman's unpublished observations indicate that the rhythm can be modified by photoperiodic treatment.

ANATOMY OF HUMAN SKIN TUMOUR CAPILLARIES

By Prof. FREDERICK URBACH and Dr. JAMES H. GRAHAM

Skin and Cancer Hospital, Unit of the Department of Dermatology,
Temple University Medical Center, Philadelphia

THE vigorous vascular proliferation at the edge of rapidly growing tumours[1], and the rich vasculature in the body of many transplantable experimental neoplasms[2] and spontaneous human tumours[3], have been clearly demonstrated. However, that the presence of large numbers of capillaries in tumour tissue does not necessarily imply an abundant supply of nutrient materials is indicated by tissue oxygen tension measurements[4] which suggest that this rich vascular bed is functionally inefficient. Recent advances in extra-corporeal perfusion techniques, the observation of potentiation of ionizing radiation effects by increased tissue oxygen tension, the suggestion that chronic hypoxia[5] and stromal changes[6] may play an important part in carcinogenesis, and that specific changes develop in cutaneous capillaries during experimental cancer induction[7,8], emphasize the importance to the oncologist of knowing more about the structure and function of tumour blood vessels.

The capillaries supplying the skin and cutaneous appendages can be easily seen in frozen sections prepared by the Gomori technique for demonstrating alkaline phosphatase. This method is superior to the

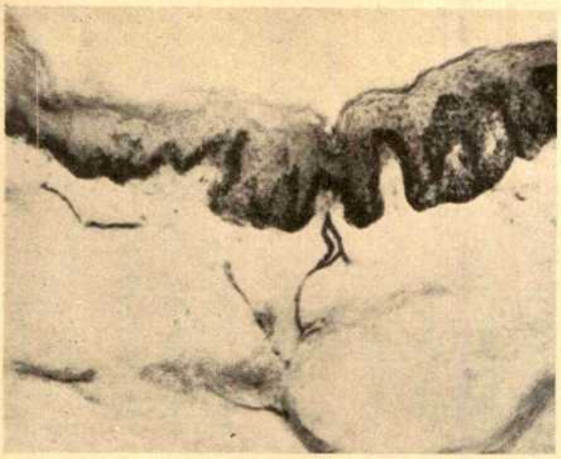

Fig. 1

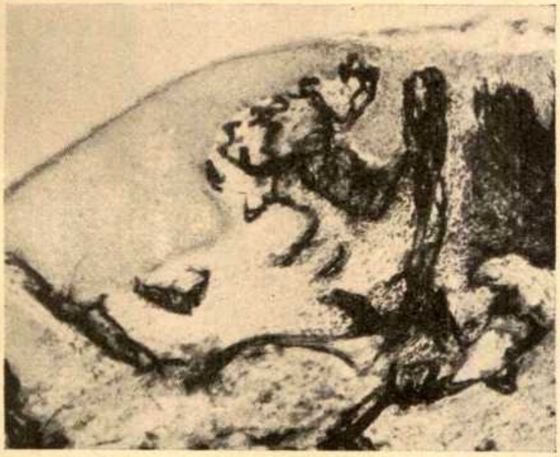

Fig. 2

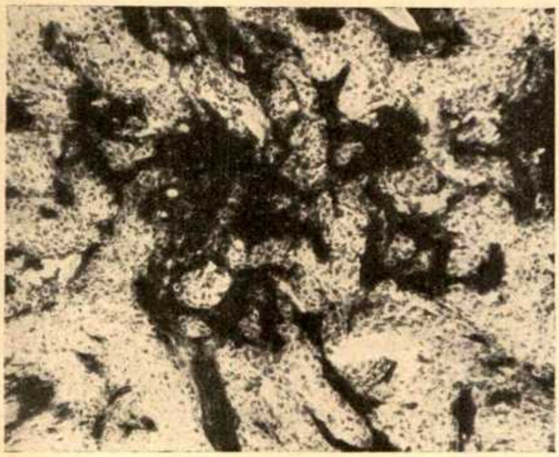

Fig. 3

conventional benzidine and silver impregnation techniques, showing even collapsed or blocked vessels of capillary calibre. Alkaline phosphatase activity appears to be intense only in the end-arterial or capillary endothelium, while the walls of venules and larger arterioles show either little or no enzyme activity.

A variety of cutaneous human pre-malignant and malignant lesions was examined, and a number of benign neoplasms and inflammatory skin diseases was investigated for control purposes. The tissue was fixed for several hours in 10 per cent cold neutral buffered formalin, and frozen sections were cut between 30 and 50μ in thickness, utilizing a Sartorius model 22 freezing microtome. The sections were prepared by the Gomori method for alkaline phosphatase[9].

The normal anatomy of cutaneous capillaries has been described by Ellis *et al.*[10], Kopf[11] and Winkleman[12]. In sections stained for alkaline phosphatase, capillary loops entering the dermal papillæ are seen, with a richer capillary plexus surrounding the cutaneous appendages (Fig. 1).

In sections of malignant skin neoplasms, the capillary structure is strikingly altered. There is a significant increase in the number of visible capillaries which are elongated, dilated and tortuous, showing many anastomoses and cross-linkages. The altered vessels surround and extend beneath the proliferating islands and strands of tumour cells of basal cell carcinomas (Fig. 2). In fifteen such specimens no capillaries were found within the neoplastic epithelium even when the tumour strand-width exceeded 300–350μ. In contrast to this picture, there are large numbers of short, widely dilated anastomosing

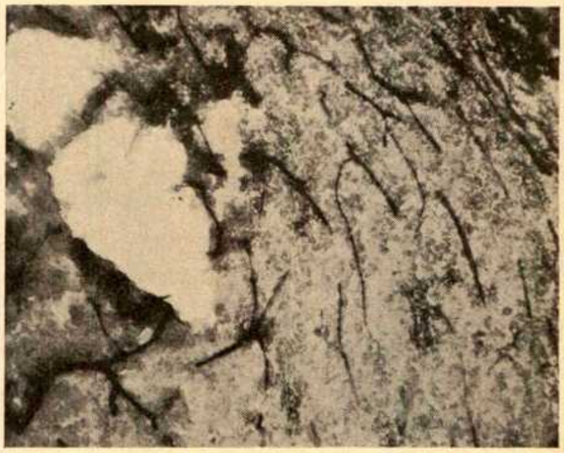

Fig. 4

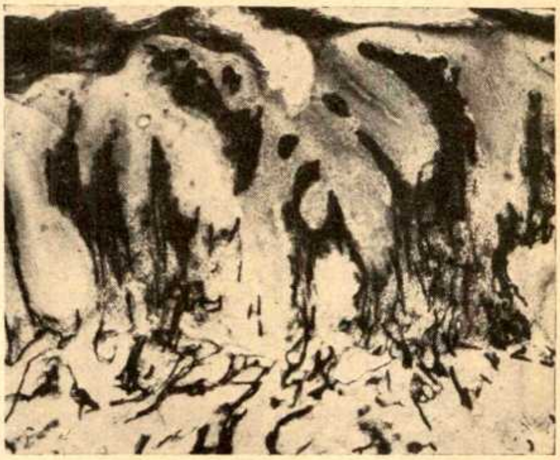

Fig. 5

capillaries in the main body of squamous cell carcinomas (Fig. 3), while in malignant melanoma the capillaries appeared to be extremely long, often arranged in parallel rows, and sometimes branching and anastomosing (Fig. 4). In both the squamous cell epithelioma and malignant melanoma, the vessels seem to be intermingled with the mass of tumour cells, unaccompanied by any significant amount of connective tissue. In the tissue surrounding both tumours there are increased numbers of altered capillaries similar to those seen around the basal cell carcinomas.

No such vessel changes have been noted in warts, nevi, xanthomas, cutaneous lymphomas or inflammatory skin diseases.

Most striking capillary abnormalities underlie the cutaneous pre-malignant lesions of senile keratosis and Bowen's disease. The changes in the vessels consist of endothelial proliferation, elongation, tortuosity, ectasia and shunting. These appear sharply at the point where epithelial hyperplasia begins, and are most evident under areas of major epithelial atypism or anaplasia (Fig. 5).

The changes in vessels found in senile keratosis and Bowen's disease correspond well to the observations of Dreifuss[8] and Kreyberg[7] in mouse skin painted with tar, and the tumour vessels seen in squamous cell carcinomas and melanomas are very similar to the description of the vascular anatomy of Algire's chamber transplanted mouse tumours[2].

Investigations are proceeding to determine whether these striking vascular changes preceded, accompany or follow experimental tumour induction, and whether similar abnormalities occur in neoplasms or other human organ systems.

HEMICHOLINIUM No. 3 AND MAMMALIAN NEUROMUSCULAR TRANSMISSION

By DR. W. W. HOFMANN, DR. G. A. FEIGEN and G. H. GENTHER

Department of Neurology, Veterans Administration Hospital, Department of Physiology, Stanford University School of Medicine, Palo Alto, California

RECENT reports suggest that at least one of the defects responsible for the weakness of myasthenia gravis is at the level of the motor nerve endings[1,2]. Desmedt has expressed the view that a failure of transmitter synthesis or release by motor nerve terminals could account for the clinical and electromyographic features of the disease[1,3]. As partial evidence he cites experiments with cats where hemicholinium compound number 3 (HC3), an agent capable of inhibiting the synthesis of acetylcholine in autonomic ganglia and in minced brain[4,5], produced a block in neuromuscular transmission. Responses to cholinesterase inhibitors were not mentioned, but the findings were interpreted as showing that HC3 could impair the synthesis or release of transmitter at motor nerve twigs. Others have referred to these experiments as evidence that the neuromuscular block after HC3 may, indeed, stem from prejunctional effects[2,6,7]; but more recent results indicate that the compound can also act directly on the end-plate[7,8], at least in certain preparations.

Dahlback *et al.* examined single end-plates directly in biopsy specimens from myasthenic patients and reported abnormally low frequencies of miniature end-plate potentials[2]. Since the miniature end-plate potential frequency could not be raised with potassium ion but the end-plate sensitivity to acetylcholine remained normal, these findings lend strong support to the concept of a prejunctional defect in the disease. In light of these observations we wished to determine whether HC3 could produce a myasthenic type of neuromuscular block in human subjects and whether, indeed, such a result might be explained on the basis of prejunctional failure.

Four volunteer subjects were examined. All were adult males with no known disease of the neuromuscular apparatus. Myasthenic subjects were not used because their known sensitivity to a number of different classes of compounds might make interpretation of results difficult. Percutaneous, supramaximal ulnar nerve stimulation was carried out in trains of 4–5 pulses at train-intervals of from 1 to 2 sec. while hemicholinium base was being given through the ipsilateral brachial artery in doses of 0·1–0·3 mgm./kilo arm weight. The evoked compound action potentials and isometric ergograph were photographed with moving film from a dual beam oscilloscope before and after drug administration. The frequency of shocks in each train was purposely made high (20–50/sec.) to maximize any effects which might depend on interference with rapid turn-over of transmitter stores. As shown in Fig. 1, HC3 was quite inert in the doses used during the time of acute exposure. The stimulations were not carried on for long periods after the arterial injections, since it appeared unlikely that any delayed type of block would develop while blood inflow was normal. It should be pointed out that, while the total doses used were slightly lower than the LD_{50} for guinea pigs[7], and considerably less than those producing neuromuscular block in the cat[1], the arterial route of administration might be expected to offset these differences to some degree. In all subjects the frequency of shocks was gradually increased after

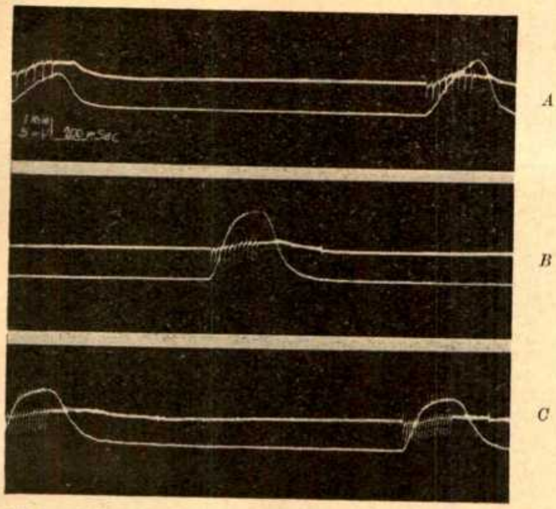

Fig. 1. Action potentials (upper trace) and tetanus tension (lower trace) in human subject in response to supramaximal ulnar nerve stimulation. All records after HC3 injection to show normal responses at high stimulation rates. *A*, 1 min. after arterial injection of 5 ml. HC3 concentration 0·1 mgm./ml., in physiological saline; *B* and *C* consecutive tracings 12 min. after *A*

injection of HC3 to see at what point the muscles would fail to 'follow'. As shown in Fig. 1*C* there was no block at very high rates[9] of stimulation.

More detailed investigations of HC3 were then made on animal preparations. The miniature end-plate potentials of rat and mouse intercostal muscles were recorded by inserting microelectrodes filled with potassium chloride into end-plate regions with a micromanipulator and microscopic visual control. The bathing solution was that described by Liley[10]. The bath temperature was kept at 37 ± 0·1° C. Miniature end-plate potentials were photographed from an oscilloscope fed by a cathode follower circuit output. Electrode resistances varied between 3 and 12 megohms. The HC3 was first given intraperitoneally to some animals prior to study in doses roughly approximating those used by others[7]. In other experiments, the agent was added to the tissue preparation before or during recording from the end-plates of individual cells in doses near those producing neuromuscular block[11]. In the first instance, two mice were killed with doses of 0·15 and 0·3 ml. of HC3, 10^{-4} mgm./ml., respectively. Each animal showed intense irritability and excitement prior to respiratory paralysis, and, even while respiration was so depressed as to cause visible cyanosis, these mice finally had such severe convulsions as to throw them clear of their cages. Miniature end-plate potentials of normal size and frequency[12] were recorded from the muscles of these animals for hours after death (Fig. 2*A*). In other experiments muscle preparations from untreated animals were soaked for 2–4 hr. in a bath of nutrient solution containing HC3, 10^{-4}–10^{-3} mgm./ml. Perfectly normal miniature end-plate potentials were also recorded from these cells. When, however, 1–2 ml. HC3, concentration 10^{-4}–10^{-1} mgm./ml., was added to the bath while microelectrodes were in place there was a rather consistent temporary lowering of miniature end-plate potential frequency without marked change in voltage (Fig. 2*B*). Any drop in amplitude could be restored promptly with neostigmine. Conversely, HC3 given after neostigmine dramatically reduced the high-voltage signals due to cholinesterase inhibition (Fig. 3). In cells from treated animals as well as from tissue soaked in HC3 the frequency of miniature end-plate potentials could be greatly increased by addition of guanidine. Subsequent application of HC3 lowered the amplitude of the miniature end-plate potentials to some degree and definitely decreased the frequency.

To discover whether the serum of myasthenic patients might contain any substance with blocking properties similar to those of HC3, serum from two patients was added to the mouse muscle preparations. Pooled serum from both patients was dialysed against the nutrient solution and a portion heated to 57° C. for 15 min. Neither sample produced the slightest change in the miniature end-plate potentials, even in an amount sufficient to replace nearly all the solution in the 15-ml. bath.

We infer from these investigations that HC3 may act at both limbs of the mammalian neuromuscular junction when applied *in vitro*. In fact, one may observe in the records from the same cell effects on quantal output frequency and, later, on amplitude, while the 'active state' is extended with other agents. On the other hand, parenteral administration of the compound seems without effect on motor nerve end-

Fig. 3. Mouse intercostal muscle. *A*, 'giant' potential 2 min. after 1 ml. neostigmine 0·5 mgm./ml. added to bath; *B*, 70 sec. after *A* and 20 sec. after 2 ml. HC3, 0·1 mgm./ml. added to bath. *B*, shows highest voltage obtained after HC3

ings, *in vivo*, even when it kills the animal. We thus agree with Schueler, who feels that neuromuscular block is not the only cause of HC3 toxicity[11]. The alterations in frequency observed when HC3 is added to the bath occur too soon to be ascribed to depletion or contamination of transmitter stores and are more probably the result of some interference with the quantal release mechanism. Since miniature end-plate potentials of substantial size (equal to pre-treatment signals) could be found when the frequency dropped, it seems unlikely that the change in frequency is due to artefact[7]. The post-junctional effects, as illustrated in suppression of the neostigmine response, develop without gross changes in the resting membrane potential and may, perhaps, be viewed as competitive inhibition. The results reported earlier in the cat might well be related to such post-junctional effects[1]. In any event, neither pre- nor post-junctional blocking properties have been observed in human subjects given HC3, and it would seem unlikely that myasthenic weakness is directly the result of the presence of this particular type of compound unless it be in greater concentration than we have used. The preliminary tests with myasthenic serum do not support the latter possibility.

This work was supported by funds from the Myasthenic Gravis Foundation and the Santa Clara County Heart Association. The hemicholinium was provided by Dr. F. W. Schueler of Tulane University Medical School.

ANTIGEN POLYMORPHISM OF A LOW-DENSITY BETA-LIPOPROTEIN. ALLOTYPY IN HUMAN SERUM

By Dr. B. S. BLUMBERG, Dr. S. DRAY and Dr. J. C. ROBINSON

National Institutes of Health, Bethesda, Maryland

It is now known that there are several families of inherited serum protein variants which constitute polymorphic systems[1]. These include the haptoglobins, transferrins, γ-globulin (Gm.) groups, group-specific components and others (for review see ref. 2). In such systems variations in the protein structures are inherited in simple Mendelian fashion, and two or more forms of the phenotype are common in the population. Individuals receiving multiple transfusions of blood of compatible red cell type would probably receive some transfusions containing serum proteins of a different phenotype from their own. Although there is no evidence that the known differences in the polymorphic serum protein systems are sufficient to lead to the development of antibodies, it was considered possible that some multiply transfused individuals would develop antibodies against phenotypes of the known polymorphic systems or against others not yet detected. Such a reaction has been examined in rabbits. Oudin[3], Dray and Young[4], and Dubiski *et al.*[5] have shown that serum proteins from individual rabbits are antigenic in other rabbits. Isoprecipitins have been found to proteins with α, β and γ mobility in agar gel[4]. As few as three or four intravenous injections of serum can lead to the production of precipitating antibodies (Dray, S., unpublished observations). This phenomenon of individual differences in antigenic specificity of proteins within a species was called 'allotypy' by Oudin[3].

Allison and Blumberg[6], using the Ouchterlony technique, studied the sera of patients who had received multiple transfusions, in an effort to detect the presence of antibodies. A precipitating antibody was found in the serum of a patient (Mr. C. de B.) with a refractory anæmia of unknown ætiology, who had received approximately fifty transfusions during the course of three years. The antibody was a 7*S* γ-globulin and it reacted with some but not all human sera to form a well-defined precipitin line. The protein with which the antibody reacted travelled as an α-globulin protein (probably of high molecular weight) in agar-gel. Family and twin studies[6] demonstrated that the presence or absence of the reacting α-globulin is under genetic control. Individuals with a single or double dose of the dominant gene designated Ag^A (phenotype $Ag(a+)$; genotypes Ag^A/Ag; Ag^A/Ag^A) reacted; those who were homozygous for the alternate allele *Ag* did not react (phenotype $Ag(a\text{-})$; genotype Ag/Ag). The polymorphism appears to be independent of the haptoglobins, transferrins, group-specific components, γ-globulin types, and of the rheumatoid factor. It appeared, therefore, that the antibody present in the blood of patient C. de B. defined a previously unknown human serum polymorphism which was designated the isoprecipitin Ag(a) system. However, the Ag(a+) protein had not been further identified.

In the present article evidence is presented that the Ag(a+) protein is a low-density β-lipoprotein. (Lipoproteins are classified as low or high density on the basis of their flotation or sedimentation in an ultracentrifuge. The low-density lipoprotein migrates as a β-globulin on paper and an α-globulin on agar-gel electrophoresis; it is usually referred to as the low-density β-lipoprotein[7].)

The gel-diffusion precipitation technique (Ouchterlony procedure) was carried out in 5 cm. Petri dishes containing 8 ml. of 0·9 per cent Oxoid 'Ionagar' (w/v) in 0·07 sodium phosphate buffer, *p*H 7·0. The method used is described elsewhere[6]. Immunoelectrophoresis was done by the micromethod of Grabar and Williams[8] and Scheidegger[9], using standard lantern slide plates coated with agar made up in barbitone buffer, 0·01 *M*, *p*H 8·4. Staining was done by a method modified from that described by Uriel and Grabar[10]. Sudan

Fig. 1. Ouchterlony experiment designed to show that the precipitin line formed between the serum of Mr. C. de B. (well 1) and an Ag(a+) individual (centre well) stains with the fat stain sudan black. Top, photograph of Ouchterlony plate before staining. Bottom, same after staining

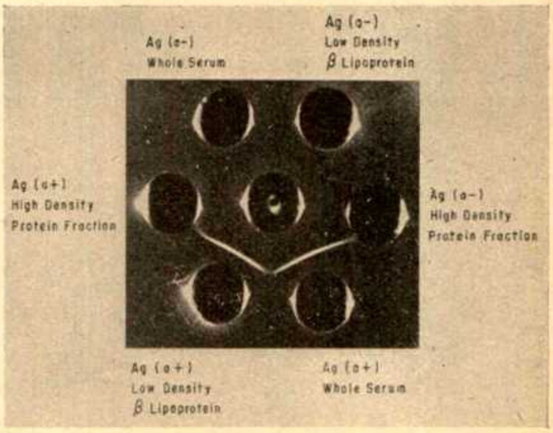
black *B* (National Aniline) was used for the lipoprotein and azocarmine (National Aniline) for the protein stain. Single-dimension starch-gel electrophoresis was by the method of Smithies[11] using the *tris*-(hydroxymethyl)-aminomethane discontinuous buffer system of Poulik[12] and filter paper insertion. Two-dimensional starch-gel electrophoresis was by the method of Poulik and Smithies[13], in which the first dimension was on paper using an acetate-barbital buffer (3·74 gm. sodium acetate and 11·04 gm. sodium barbital in 1 litre of distilled water) and the second dimension was in gel using the *tris* buffer. Agar-gel electrophoresis was performed on standard lantern slides using the same conditions as for immunoelectrophoresis. The isolation of $7S$ γ-globulin was by the method of Levy and Sober[14]. The low- and high-density lipoproteins were separated from each other by ultracentrifugation in a high-density salt medium using whole serum and the method of Havel *et al.*[15]. Two fractions were separated, one of a density lower than 1·063 (low-density lipoprotein) and the second greater than 1·063 (high-density).

Fig. 1 is a photograph of an Ouchterlony experiment before and after staining with sudan black. It was designed to show that the precipitin line formed between the serum of Mr. C. de B. (well 1) and an Ag(a+) individual (centre well) stains with sudan black. A positive control was obtained by reacting rabbit anti-β-lipoprotein (well 6) with the serum of Mr. C. de B. and the Ag(a+) individual; the two precipitin lines coalesce and both also coalesce with the precipitin line formed between the serum of Mr. C. de B. and the Ag(a+) individual (first and centre well). It appears that the rabbit anti-β-lipoprotein and the serum of Mr. C. de B. precipitate the same protein. The precipitin line between horse anti-human serum (well 3) and the Ag(a+) serum (centre well) served as another positive control. Two precipitin systems were used for negative controls: (1) between horse anti-human serum (well 3) and isolated α-macroglobulin (which contains no lipoprotein) (well 2); and (2) between horse anti-γ-globulin (well 5) and the Ag(a+) serum (centre well). Neither of these lines stained with sudan black.

Fig. 2 is a photograph of an Ouchterlony plate designed to compare the reactions of low- and high-density lipoproteins prepared from the serum of Ag(a+) and Ag(a−) individuals. Mr. C. de B.'s serum reacts only with the whole serum and the low-density β-lipoprotein of the Ag(a+) serum but not with the high-density lipoprotein. As expected, Mr. C. de B.'s serum does not react with the Ag(a−) whole serum or the fractions thereof. The sera of 8 other Ag(a+) and 8 other Ag(a−) individuals were tested in the same way and the same results as mentioned here were obtained.

Fig. 3 is a photograph of the results of a starch-gel electrophoresis experiment which compares whole serum and the low-density β-lipoprotein fraction from the serum of the same individual. The lipoprotein was approximately three times its concentration in whole serum. It migrates a single well-defined band (broken arrow).

Fig. 4 is a photograph of an immunoelectrophoresis experiment designed to show the reaction between the concentrated $7S$ γ-globulin (isolated from the serum of Mr. C. de B.) with whole serum, and with high- and low-density lipoprotein. As seen in Fig. 2, the whole serum and the low-density lipoprotein from an Ag(a+) individual reacted to give precipitin lines, but the high-density lipoprotein did not. (As in the



Ag (a−) Whole Serum
Ag (a−) Low Density β Lipoprotein
Ag (a+) High Density Protein Fraction
Ag (a−) High Density Protein Fraction
Ag (a+) Low Density β Lipoprotein
Ag (a+) Whole Serum

Fig. 2. Photograph of Ouchterlony experiment designed to show that the C. de B. serum (centre well) reacts only with the low-density β-lipoprotein fraction of the serum of an Ag(a+) individual. Photograph of unstained plate

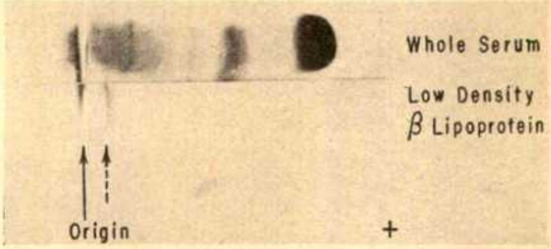


Fig. 3. Photograph of a starch-gel electrophoresis experiment in which the low-density β-lipoprotein fraction is compared with the whole serum from which it was isolated. The longer arrow shows the position of the origin, and the broken arrow, the position of the single lipoprotein band. Amido black stain

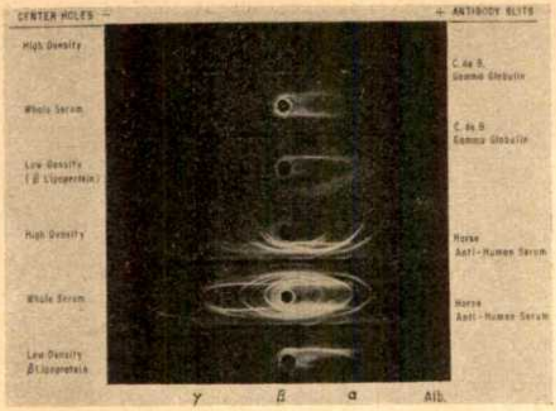

Fig. 4. Immunoelectrophoresis experiment designed to show the reaction between the γ-globulin isolated from the serum of Mr. C. de B. and the serum of an Ag(a+) individual and the high-density and low-density fractions separated from the serum. The reactions between horse anti-human serum and the same antigens are shown for comparison. The approximate position of the major protein bands are shown. Photograph of unstained plate

Ouchterlony plates, the precipitin lines stained intensely with sudan black (not shown).) Horse anti-human serum also reacted with the whole serum and high- and low-density lipoproteins. By comparison with the horse anti-human serum, it is seen that the low density β-lipoprotein migrates in the agar gel with the electrophoretic mobility of an α-globulin as previously reported[6].

The experiments summarized here have shown that the low- but not the high-density ultracentrifuge fraction of the serum of an Ag(a+) individual precipitates in agar gel with the 7*S* β-globulin antibody of Mr. C. de B. (Fig. 2). The precipitin line stains with the lipid stain, sudan black B; it coalesces with a precipitin line found in rabbit anti-human β-lipoprotein and human serum (Fig. 1). The antigen has the mobility of an α-globulin on agar gel (Fig. 4) and migrates as a single band between the origin and the slow α-two globulin on starch-gel electrophoresis (Fig. 3). These experiments identify the antigen as the low-density β-lipoprotein.

The whole serum, low-density and high-density fractions of 45 Ag(a+) and 35 Ag(a−) subjects were analysed for total cholesterol, total phospholipid and the total cholesterol/phospholipid ratio. (We are indebted to Dr. D. S. Fredrickson for supplying these data.) There were no significant differences in these broad lipid classes between the Ag(a+) and Ag(a−) individuals. It would be of interest if chemical differences in the β-lipoproteins of Ag(a+) and Ag(a−) individuals could be found.

In an experiment designed for other purposes, two chimpanzees were immunized with a single injection of whole human serum of an Ag(a−) individual plus complete Freund's adjuvant. Serum was obtained four weeks later. Both the animals developed precipitating antibody to human low-density β-lipoprotein as evidenced by a single band in agar gel. The chimpanzee antibody reacted with 225 normal American human sera tested and did not distinguish between Ag(a+) and Ag(a−) individuals. When the chimpanzee sera were used instead of rabbit anti-β-lipoprotein serum, coalescence was seen between the three precipitin lines similar to that observed among the centre, first and sixth wells of Fig. 1. Further immunization experiments with lower primates are in progress. We hope to obtain antibody which will distinguish individual differences in human β-lipoproteins.

This article, in conjunction with the genetic data presented elsewhere[6,16], establishes that a genetic polymorphism exists in the human low-density β-lipoprotein. The factors which maintain this polymorphism are unknown, although they may be related to diseases in which the lipoproteins are involved, such as some kinds of arteriosclerosis, diabetes and coronary heart disease. It would be of interest to determine if antigenic polymorphisms of β-lipoproteins (allotypy) occur in species other than man; for example, in rabbits, where allotypy for the α- and β-globulin has already been reported.

VISION IN INSECTS IN TERMS OF THE ELECTRICAL ACTIVITIES OF THE DESCENDING NERVE FIBRES

By NOBUO SUGA and YASUJI KATSUKI

Department of Physiology, Tokyo Medical and Dental University, Yushima, Bunkyo-Ku

SINCE Frisch's work[1], good colour discrimination in a honey-bee has been demonstrated by behavioural and electrophysiological studies. The behaviour of an insect to light stimuli must be activated by the descending fibres from the brain to the thoracic ganglia. Examining the response patterns and the spectral sensitivity curves of the descending fibres from the ocelli and compound eyes to the thoracic ganglia is a simple way to understand the ability of the colour discrimination in an insect rather than studying the receptor mechanism. With this view, we tried to record the impulse discharges of the descending fibres from the eyes with such a purpose. The material used was a species (male) of grasshopper, *Gampsocleis buergeri* (Orthoptera).

In order to learn what information is sent out over the brain, impulse discharges were recorded of descending fibres at the connective immediately

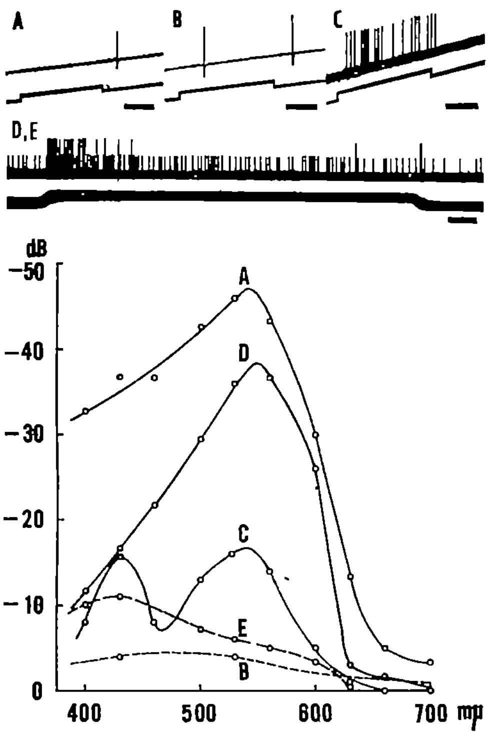

Fig. 1. Top, responses (upper beam) to white light (lower beam) of five descending fibres from the ocellus (*A*) and the compound eye (*B*, *C*, *D* and *E*). The horizontal line in each photograph shows 0·1 sec in *A*, *B* and *C* and 1 sec. in *D*, *E*. Bottom, spectral sensitivity curves of five descending fibres. Curves *A–E* correspond to the responses (*A–E*) shown in the top figure

before the thoracic ganglia connecting with the motor nerves to legs and wings, that is, the sub-œsophageal-prothoracic connective. Ten monochromatic lights with equal energy were produced from neutral density and interference filters and a tungsten filament lamp. The intensity of light was attenuated by neutral density filters. A micro-electrode filled with 3 *M* potassium chloride was inserted into the connective after destroying the prothoracic ganglion. The ocelli or compound eyes were cauterized with a platinum wire heated electrically in order to decide from which eye impulses descended.

A descending fibre from the lateral ocellus run in the contralateral nerve cord, because the response to the illumination on the lateral ocellus was recorded from the cord opposite the stimulated eye. The fibre spontaneously discharged impulses in the dark at the rate of 40–80/min. Spontaneous discharges of this fibre vanished when the lateral ocellus was cauterized. When the lateral ocellus was placed in the light, spontaneous discharges were completely inhibited. A few impulses appeared in a group after the cessation of a light stimulus. Thereafter, spontaneous discharges were suppressed for several hundred msec. With a long illumination period off discharge was enhanced and the latency became short. The after-effect of a stimulus remained for a long time, and it took several seconds after off response in order to return to the original rate of spontaneous discharges. When the lateral ocellus was regularly exposed to light stimuli at the rate of 1 flash/3 sec., long after-effects summed up one another, and no spontaneous discharges, but off responses, were observed (Fig. 1*A*, top). Off response was evoked even by a very short flash lasting 4 msec. Flash-light delivered on the median ocellus evoked off response on the descending fibre from the lateral one. Spontaneous discharges of this fibre in the dark were almost uninfluenced by cauterizing the median ocellus. The number of impulses in off response was less by about one-third after cauterizing the median ocellus than that in normal conditions. Therefore, the neural activity of the median ocellus will be similar to that of the lateral one and will be divided into a pair of descending fibres from the lateral ones. The spectral sensitivity curve shown by off response was on the wave-length of less than 400–700 mμ, the most sensitive spectrum being about 540 mμ (Fig. 1*A*, bottom). The curve did not change even if it was measured after cauterizing either the lateral or median ocellus and the threshold of the response to a light stimulus was always lower than those of the descending fibres from the compound eye.

Descending fibres from the compound eye were classified into four types. Each of them was characterized by the spectral sensitivity curve and also the discharge pattern. One of them showed on–off response. This neuron discharged only two spikes at the onset and cessation of a light stimulus when its intensity was strong. The off response was unstable compared with the on response and disappeared at first by decreasing the light intensity. The neuron had a very high threshold in spite of the fact that the neuron was activated by the light of 400–700 mμ and was more sensitive to the light of 430–530 mμ (Fig. 1*B*, top and bottom). The second type of the neuron was characterized by the spectral sensitivity curve, which extended from less than 400 to 630 mμ and had two peaks at about 430 and 540 mμ. The neuron discharged many impulses by a flash light-stimulation (Fig. 1*C*, top and bottom), but it adapted quickly to a long illumination. The discharge pattern of the third type of the neuron to the short flash light was mainly the on type. When the compound eye was illuminated for a long time, the discharge-rate of the neuron decreased gradually to zero and a few impulses were found on cessation of the stimulus. The neuron was characterized by the spectral sensitivity curve with a peak at 540 mμ (Fig. 1*D*, top and bottom, large spikes). The fourth type of the neuron showed the strong response to the light stimuli with short wave-length. The most effective spectrum seemed to be found at 420 mμ. This neuron often produced many spontaneous discharges and showed on response. When a light stimulus was applied on the compound eye, the discharge-rate of the neuron increased at first and thereafter decreased slowly to the original level of spontaneous discharges (Fig. 1*E*, top and bottom, small spikes). The results obtained with microelectrodes did not reveal how many descending fibres there were, if they showed similar discharge patterns and spectral sensitivity curves. The external recording from the whole connective was made by hooking it up in the air by a fine silver wire electrode. In favourable cases, the responses of four descending fibres from the compound eyes as described here were recognized by their different spike heights. More than four descending fibres were not found. By cauterizing the contralateral compound eye, almost all their impulses disappeared and a few impulses remained there. They seemed to be those of the second and the third type of neuron. Therefore, descending impulses from the compound eye were mainly transmitted to the contralateral fibres.

Quite recently, it was revealed that on and on–off responses of neurons were recorded at the optic lobe of an insect, but no off response[2]. The off response is, however, known to be evoked by light stimulation on ocelli[3]. It is an interesting fact that three types of responses similar to those in vertebrate eyes are elicited by light stimulation on two kinds of the eyes in the insect. The descending fibre from the ocelli showed pure off response to a light stimulation, while those from the compound eyes were characterized by on and on–off responses though off in on–off response was very faint as compared with on. We cannot interpret the meaning of the difference in those response patterns. It may, however, be suggested that three kinds of the response patterns (on, on–off, and off responses) are not concerned with the colour discrimination, but the pattern discrimination, because the response patterns of the axons of all primary sensory cells are on type in *Limulus*[4] and insects[5], but the other types of the responses are recorded from the region beyond synapses[2,6].

The ocellus seems to correspond to the rods in a vertebrate eye, because its descending fibre has the lowest threshold, while the compound eye with several kinds of descending fibres seems to correspond to the cones and have a more complex function than the ocelli. Though the response pattern results from intensity, pattern, and colour discriminations by the complex neural network in the optic lobe and the brain, each of the descending fibres from the ocelli and compound eyes is characterized by a different kind of a response pattern and a different spectral sensitivity curve. Therefore, it may be supposed that five descending fibres from the eyes evoke different kinds of neural activities and the insect is able to discriminate colours to some extent. The spectral sensitivity curves are limited to the red colour; but they seem to extend toward the ultraviolet, and are thus different from those of vertebrate eyes. If the thresholds of the descending neurons for ultra-violet are measured, a more conclusive answer to colour discrimination may be obtained. Phototaxis in insects is well interpreted by the fact that almost all impulses from two kinds of the eyes are transmitted to the contralateral descending fibres and activate the contralateral motor organs, the wings and the legs.

EFFECTS OF HETEROGENEOUS POPULATIONS ON RADIATION SURVIVAL CURVES

By Dr. WILLIAM C. DEWEY and Dr. ARTHUR COLE

Physics Department, University of Texas, M. D. Anderson Hospital and Tumor Institute, Texas Medical Center, Houston 25, Texas

MANY sigmoid or multi-hit curves representing the survival of cells exposed to radiation have appeared in the literature. Examples are those of Puck[1] and Elkind and Sutton[2], showing curves of the type described by the equation:

$$S = 1 - (1 - e^{-D/D_0})^n \qquad (1)$$

where S is the fraction of the population surviving a radiation dose, D, and $n \geqslant 1$. The value of n, called the extrapolation number[3], is determined by extrapolating the straight-line portion of the plot of log survival versus dose to $D = 0$. The mean lethal dose, D_0, is the increment of dose on this straight line portion corresponding to an incremental reduction of survival to 37 per cent (that is, $1/e$) of an initial value. In practice, the accuracy in graphically estimating values of n and D_0 from a plot of equation (1) depends on the portion of the curve used for making the extrapolation and the magnitude of n. If the extrapolation of the slope of the curve is made at survival values between 0·1 and 0·01, the value for D_0 will be in error less than + 4 per cent for $n < 100$, and the value for n will be in error about: − 8 per cent for $n = 2$, − 13 per cent for $n = 10$, and − 25 per cent for $n = 100$. The accuracy improves at lower survival values. The value of n is sometimes interpreted as the number of targets which must be inactivated in the cell in order to produce lethality, and the value of D_0 is sometimes interpreted as the dose required to inactivate one target. Implicit in these interpretations, however, is the assumption that the population of cells being irradiated is a homogeneous group with regard to radiosensitivity.

Atwood and Norman[4] considered the effect of heterogeneity on the shape of the survival curves for the situation in which a population consisted of several groups, each of which has the same D but$_0$ a different value for n. The resultant survival curve has the same D_0, but the value for n is an arithmetical average of the individual n's. In such a case, the difference between the survival of a homogeneous group and a heterogeneous population could be detected only if a plot of $-\log\,(1 - S)$ versus D could be accurately determined.

Examples of heterogeneities in radiation sensitivity have been reported for yeast cells[5], *Escherichia coli*[6], and animal cells[7-9]. For *E. coli* and animal cells, the radiation sensitivity depends on the stage of the cell in its mitotic cycle. For example, animal cells in the process of synthesizing deoxyribonucleic acid (DNA) are about twice as radiosensitive as those in the period preceding DNA synthesis. Therefore, if information is to be deduced from shape of survival curve, it is important to consider further the effect of such heterogeneities.

In contrast to Atwood and Norman's analysis, in which the population is divided into groups having different values of n, our analysis is made for a population which is divided into groups with different values of D_0. Theoretical survival curves are calculated for a population of cells divided into several groups, A, B, . . ., i . . ., which have the same extrapolation number, n, but which have different values for D_0. The general equation for the survival curve is:

$$S = 1 - C_A(1 - e^{-D/D_A})^n - C_B(1 - e^{-D/D_B})^n \ldots - C_i(1 - e^{-D/D_i})^n \ldots \quad (2)$$

where C_A, C_B, . . . C_i . . ., are the fractions of cells in each group, and the values of D_0 for each group are D_A, D_B, . . . D_i . . ., respectively. The first term binomial expansion of this equation is :

$$S = C_A n e^{-D/D_A} + C_B n e^{-D/D_B} \ldots + C_i n e^{-D/D_i} \ldots \quad (3)$$

When the fractional survival of each group is less than 0·1, equation (3) differs from the complete expression, equation (2), by only a small amount, that is, 0 for $n = 1$, less than 4 per cent for n up to 6, and less than 11 per cent for n up to 100. For $D_A > D_B$, . . . D_i . . . and for doses sufficiently large where all but the first term becomes negligible:

$$S = C_A n e^{-D/D_A} \quad (4)$$

The extrapolation number for this curve is $C_A n$, rather than n, and the value for D_0 is equal to D_A, that is, the mean lethal dose for the most resistant group.

In Fig. 1, the survival curves as calculated from equation (1) are shown for a population divided into two groups with $n = 2$, and with $D_0 = 100$ for one group (curve B), and $D_0 = 200$ for the other group (curve A). The composite curve (C), as calculated from equation (2), for a population divided equally into the two groups is also shown. Curve (C) shows a D_0 of 200 corresponding to the D_0 of the resistant group and an apparent extrapolation number, as determined by the shape of the curve below the first decade, equal to 1·0, that is, half the value of n for the individual groups. However, in the first decade a slight inflexion is noted. The greatest difference between the survival curve (C) for the heterogeneous population and one for a homogeneous population with $n = 1$ and $D_0 = 200$ (not shown) is 18 per cent; this occurs at a dose value of 100, that is, $\frac{1}{2}D_0$ for the resistant group. Therefore, in order to distinguish experimentally the survival curve obtained for a heterogeneous population consisting of two such groups with $n = 2$ from an exponential survival curve expected for a homogeneous 'single-hit' population, a detailed experimental study of the first decade survival would be needed.

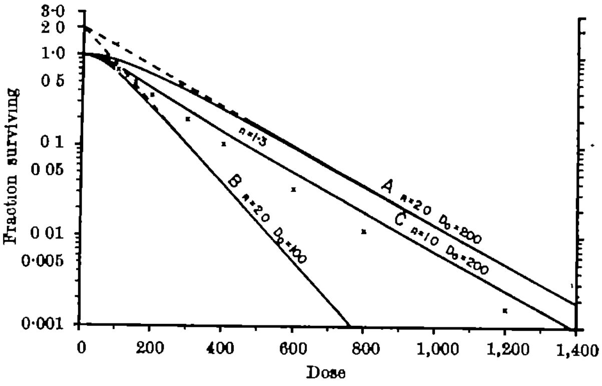

Fig. 1. Theoretical survival curve (C) for a heterogeneous population of cells divided equally into two homogeneous groups, A and B, with $n=2$ and values for D_0 as indicated. The straight line portions are extrapolated to $D=0$ to obtain n. Curve (C) differs from a purely exponential response (that is, $n=1$) by a maximum of 18 per cent. The value of 1·3 for n would be obtained in curve (C) if the extrapolation were made from the first decade of the curve. The points, X, are for a population consisting of 0·3 of the cells with the radiosensitivity of group A and 0·7 with the radiosensitivity of group B

Survival points (the X's) are also shown in Fig. 1 for the population of cells divided into two unequal groups by a ratio of 3 : 7, the larger and more sensitive group having a D_0 of 100 and the smaller and more resistant group having a D_0 of 200. In this case, the extrapolation number is reduced to 0·6 and in the first decade the survival curve is concave upward.

The curves in Fig. 2 are calculated for two equal groups on the same assumptions as those in Fig. 1 except that $n = 10$. Again, the composite curve (C) for the heterogeneous population has an apparent extrapolation number half the value of n for the individual groups and a mean lethal dose identical with that of the resistant group. Survival points are also shown for a homogeneous population with an extrapolation number of 5 and a D_0 of 200, that is, values corresponding to the apparent values resulting from the heterogeneous population. The greatest difference (8·6 per cent) between the survival curves for the homogeneous and heterogeneous populations occurs at a dose of about 400, that is, $2D_0$ for the resistant population. Again, the small difference in survival curve shape between a homogeneous and a heterogeneous population could be resolved only if precise experimental observations were made in the first decade of the survival curve.

The part of the survival curve which should be investigated carefully in order to detect heterogeneities depends on the fraction of the population composed of the resistant group, the mean lethal dose of the resistant group compared with that of the other groups, and the extrapolation number. By using equation (2), it is possible to determine the survival level below which only one group in the population provides a major contribution to the survivors. The same information can be obtained from equation (3), the approximation to the survival curve. If the

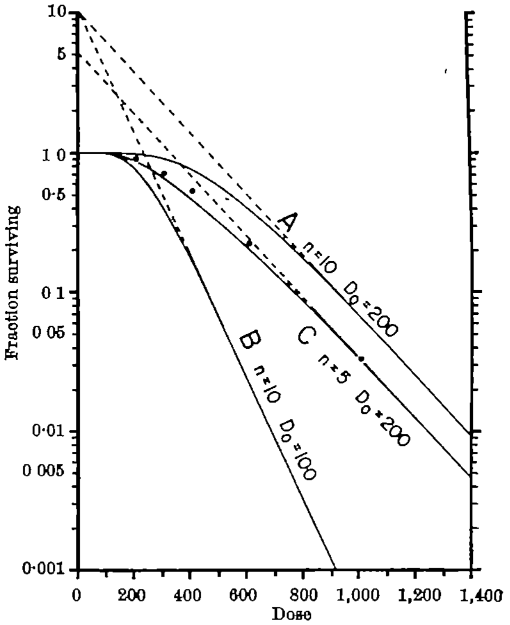

Fig. 2. Theoretical survival curve (C) for a heterogeneous population of two equal groups, A and B, as illustrated in Fig. 1, but with $n=10$. Curve (C) has an apparent n equal to 5. The dots shown indicate the response of a homogeneous population with $n=5$ and $D_0=200$ (equation (1)) and differ from (C) by a maximum of 9 per cent

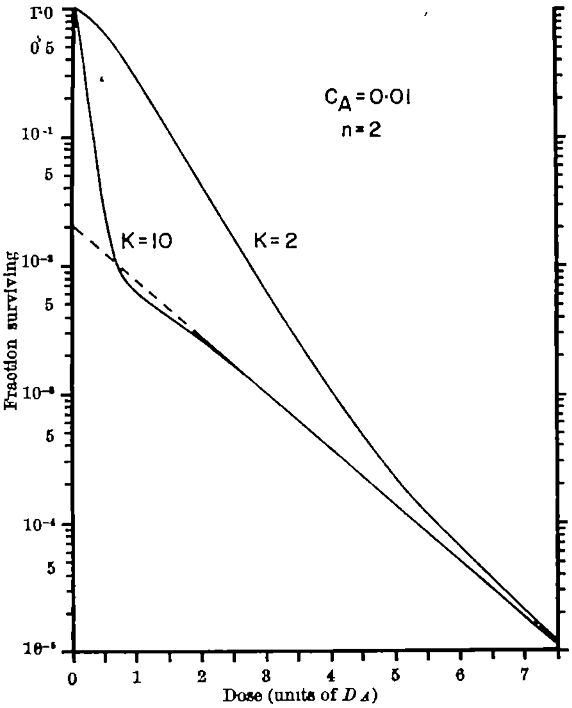

Fig. 3. Theoretical survival curves for populations of cells in which 0·99 of the cells are in a radiosensitive group and 0·01 ($C_A = 0{\cdot}01$) of the cells are in a radioresistant group. For both groups $n = 2$, but the mean lethal dose, D_A, of the radioresistant group is K times the mean lethal dose of the radiosensitive group

population is divided into two groups, a resistant fraction A and a sensitive fraction B, with $D_A = KD_B$ where ($K \geqslant 2$), it can be determined at what dose value the sensitive fraction becomes negligible by setting the second term in equation (3) equal to 0·1 of the first term. The dose when this occurs will be:

$$D = \frac{D_A}{K - 1} \ln \frac{10(1 - C_A)}{C_A} \qquad (5)$$

The fractional survival for this dose can be determined by substituting this value of D into equation (2). This approximate method for estimating D leads to an error in S, which is greatest when n is large; however, when $1 \leqslant n \leqslant 10$ the value of S will be accurate to within a factor of 2. In extreme cases with n and K approaching 100, the estimate of S, using the value of D from equation (5), approaches a factor of 10 higher than an exact solution using equation (2). This is still sufficient to define the decade of the fractional survival during which a resistant group dominates the remaining population.

When at least one-half of the cells are in the resistant group ($C_A \geqslant 0{\cdot}5$) with $1 \leqslant n \leqslant 100$ and where K varies from 2 to 100, the number of cells in the sensitive group will become negligible during the first decade of the survival curve. Therefore, a heterogeneity produced by a sensitive group, consisting of less than one-half of the population, would lead to a survival curve that would differ in the first decade only from a typical survival curve for a homogeneous population.

Conversely, when the resistant cells compose only a small fraction of the population, the survival curve approaches that of the resistant cells at survival values less than 0·1. For example, when only 0·01 of the cells are in the resistant group ($C_A = 0{\cdot}01$) with $1 \leqslant n \leqslant 100$ where K varies from 10 to 100, the number of sensitive cells will become negligible when the survival decreases to about 0·01 ($S \cong C_A$), as shown in Fig. 3. However, for $K < 10$, the sensitive cells will drop out at lower survival values depending on n. For example, for $K = 2$, the relevant survival values are 10^{-5} for $n = 2$ as shown in Fig. 3, 10^{-4} for $n = 10$, and 10^{-3} for $n = 100$. Therefore, in order to detect resistant cells which compose less than one-tenth of the population, it is necessary to investigate the survival curve below the first decade.

Based on the previous discussion, it is apparent that if a population of cells is heterogeneous with regard to radiosensitivity, the observed survival curve may appear to have an extrapolation number and a mean lethal dose quite different from those applicable to each group of the population. When the survival curves are used for interpretations of the mechanism of radiation action, these considerations are important.

INTERACTION OF THE OXYGEN EFFECT AND RADIOSENSITIZATION PRODUCED BY BASE ANALOGUES INCORPORATED INTO DEOXYRIBONUCLEIC ACID

By Prof. HENRY S. KAPLAN, RICHARD ZAVARINE and JOHN EARLE

Department of Radiology, Stanford University School of Medicine, Palo Alto, California

When bacterial or mammalian cells are grown under appropriate conditions in the presence of certain pyrimidine or purine analogues, they incorporate into their newly synthesized deoxyribonucleic acid (DNA) varying amounts of these analogues instead of the corresponding natural bases[1–6]. Cells the DNA of which contains appreciable amounts of such analogues are abnormally sensitive to both ultra-violet and ionizing radiations[7–10]. The increase in X-ray sensitivity is most conveniently expressed by the ratio of slopes of the dose–log survival curves for analogue versus natural-base-grown cells. Slope ratios of approximately 2·0 have been obtained with the halogenated pyrimidines, 5-bromo- and 5-iodouracil acid (BU, IU) and their deoxyribosides (BUDR, IUDR)[8–10] as well as with the purine anal-

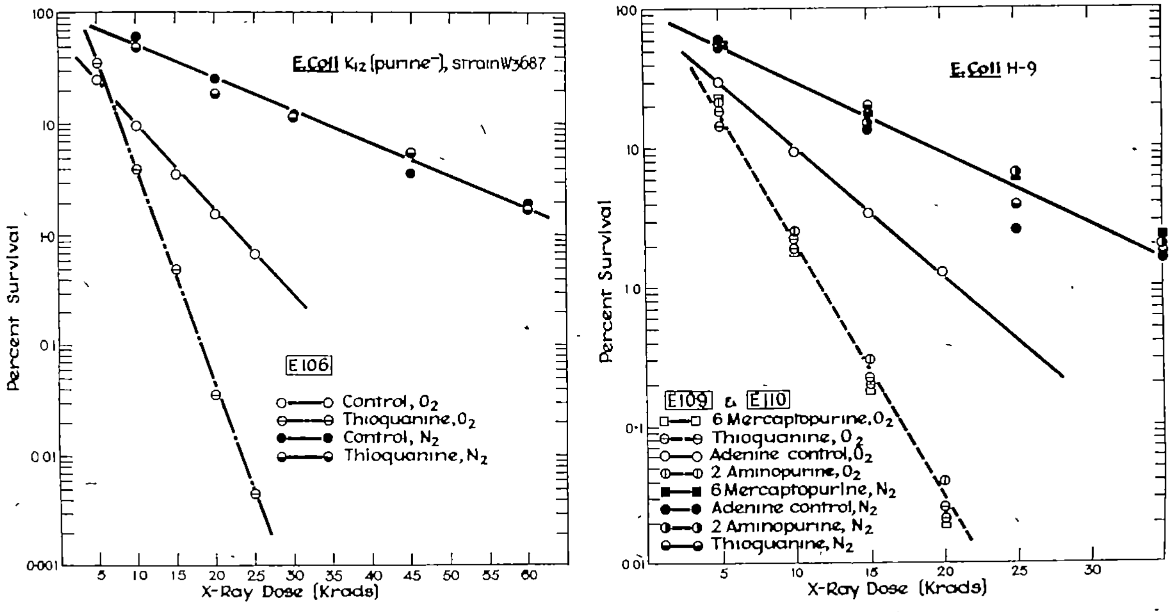
ogues 6-thioguanine (TG)[9], 6-mercaptopurine (6-MP), 2-aminopurine (2-AP), 8-azaguanine, 6-methylmercaptopurine and 2-mercapto-6-aminopurine[11].

It has long been known that oxygen sensitizes virtually all biological systems, and many chemical reactions as well, to inactivation or alteration by ionizing radiations[12]. This enhanced response has been termed the 'oxygen effect'. This article reports a series of experiments undertaken to study the interaction between the oxygen effect and the radiosensitization produced by the base analogues.

Several mutants of *Escherichia coli* were used. These included a thymine-deficient mutant of strain *B* (*W*4516) and a purine-deficient mutant of strain *K*12 (*W*3687), provided by Dr. Esther Lederberg of the Department of Genetics, Stanford University, and nitrosoguanidine-induced[13] purine-deficient mutants of strain *H* (*H*-9, *H*-515) and strain *S* (*Sng* 1–14), provided by Dr. Joseph Greenberg of the Palo Alto Medical Research Foundation. Pre-irradiation culture conditions were as previously described[9,10]. X-irradiation was carried out at 250 kV., 15 m.amp., 17·8 cm. distance, no added filter, average dose-rate 1,190 rads/min. The X-ray beam was directed vertically upwards into four buffer suspensions of bacteria (two analogue-grown, two control) contained in 30-ml. flat-bottomed glass vials fixed to the centre of a 'Plexiglass' plate, which was held in the cone-holder of the X-ray tube housing. Each vial was provided with a green rubber stopper through which a short (outlet) and a long (inlet) capillary glass tube passed; the latter extended almost



(a) (b)

Fig. 2

Table 1. Slope Ratios of Dose–Log Survival Curves of *E. coli* after X-irradiation in Nitrogen or in Oxygen

Analogue	Analogue (O_2) / Control (O_2)	Analogue (N_2) / Control (N_2)	Control (O_2) / Control (N_2)	Analogue (O_2) / Analogue (N_2)
BU	2·07	3·08	3·33	2·36
IU	1·60	1·53	2·54	2·67
TG	2·02	0·9–1·1	1·85–2·36	4·0
6-MP	2·02	0·9–1·1	1·85–2·36	4·0
2-AP	1·93	0·9–1·1	1·85–2·36	3·8

to the bottom of the vial and was bent at its tip so that the emerging fine bubbles of gas would impart a swirling, mixing motion to the bacterial suspension. Oxygen (medical grade) was bubbled through two vials (one analogue, one control), nitrogen through the other two. The nitrogen (pre-purified grade, Mathison Co.), which was stated to have a maximum of 20 p.p.m. of oxygen, was passed through a heated 4·5 × 80 cm. glass tube packed with copper wire to remove the last traces of oxygen. Both gases were humidified by passage through water, and flow-rates were adjusted to approximately 0·5–1·0 l./min. The humidifying flasks and tubing were equilibrated for 30 min. and the bacterial suspensions for 20 min. prior to irradiation. Immediately prior to irradiation and at each desired X-ray dose-level, an aliquot of each bacterial suspension was aspirated without interruption of gas flow, after which irradiation of the remaining organisms was resumed. The bacterial samples were appropriately diluted, plated on yeast extract agar (purine-deficient mutants) or on nutrient agar fortified with 200 μgm./ml. of thymine (thymine-deficient mutants), and incubated at 37° C. overnight. Survival curves were plotted on semilog paper from the viable colony count at each dose-level (average of 4–8 plates per point) as a fraction of the viable count of the corresponding unirradiated sample. Results are summarized in Table 1, and representative dose–log survival curves are presented in Figs. 1 and 2, respectively. The two halogenated pyrimidine analogues tested, BU and IU, exerted the same radiosensitizing effect whether X-irradiation was carried out in oxygen or in nitrogen. In contrast, the radiosensitization noted under oxygenated conditions with three purine analogues tested to date (TG, 6-MP, 2-AP) completely disappeared when X-irradiation was carried out in the absence of oxygen.

No obvious difference between purines and pyrimidines with respect to the oxygen dependence of their radiochemical degradation has been apparent when aqueous solutions of the natural bases were X-irradiated *in vitro*[14,15]. Perhaps comparable studies with aqueous solutions of the base analogues will elucidate the mechanism of the present unanticipated but unambiguous *in vivo* results. Parallel *in vivo* experiments with neutrons and other high-LET radiations might also be illuminating.

These investigations were aided by grant C–3353 from the National Cancer Institute, National Institutes of Health, U.S. Public Health Service, and were carried out in part in the laboratories of the Department of Biochemistry, Stanford University, during the senior author's sabbatical leave. We thank Prof. Arthur Kornberg for the facilities made available for this and related work.

EVIDENCE FOR A PARTICULAR BASE ALTERATION IN TWO *T*4 BACTERIOPHAGE MUTANTS

By Dr. JANE K. SETLOW

Biology Division, Oak Ridge National Laboratory*, Oak Ridge, Tennessee

THE particular nucleotide which is altered by ultra-violet light in producing a mutation can theoretically be determined by action spectra. An action spectrum should reflect the absorption spectrum of the affected nucleotide, provided the deoxyribonucleic acid (DNA) is irradiated in the disordered condition, when there is little transfer of energy from one base to another[1,2]. The DNA of *T*4 is in the disordered state 7 min. after infection, as judged by the action spectrum for killing (Fig. 1). This action spectrum is similar to that reported for *T*2 (ref. 3). Point mutants for the r_{II} region of *T*4 apparently differ from wild-type by a small number of nucleotide pairs[4], possibly one. Thus, a reversion might require a change in only one nucleotide. The results presented here favour this approach in that action spectra for reversion of two r_{II} mutants irradiated at time 7 min. suggest a particular nucleotide change.

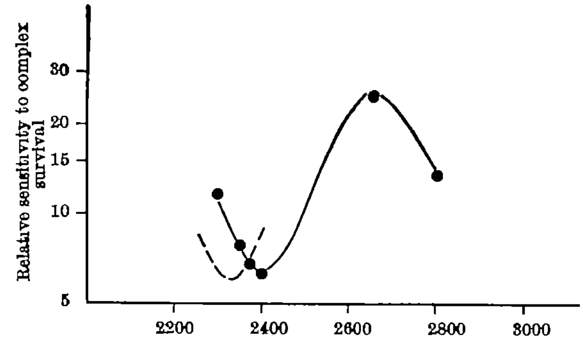

Fig. 1. Action spectrum of ultra-violet killing of *T4-E. coli* complexes (multiplicity of 7) at time 7 min. in the latent period. Each point represents the slope of the straight line portion of a semilogarithmically plotted survival curve with survival-levels down at least to 10^{-3}. The dashed line is from an action spectrum for ordered DNA[2]

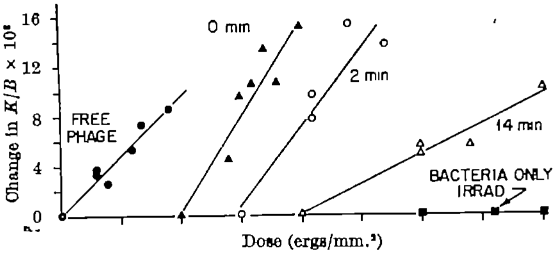

Fig. 2. Reversion of AP156 with 2652 Å. radiation at different times in the latent period. Straight lines were fitted by least squares. Each increment of dose is 500 ergs/mm.². The first point for each time represents zero dose. The ordinate is the change in the ratio of plaque counts on K to plaque counts on B

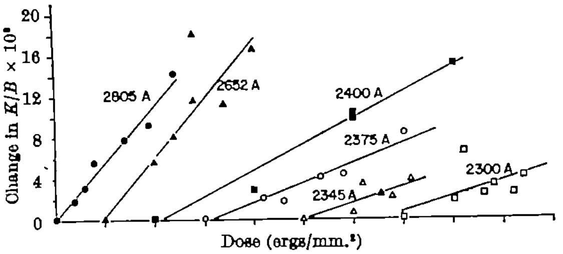

Fig. 3. Reversion of AP156 with irradiation at time 7 min. in the latent period. Straight lines were fitted by least squares. Each increment of dose is 500 ergs/mm.². The first point for each wave-length represents zero dose. The ordinate is the change in the ratio of plaque counts on K to plaque counts on B

Measurement of reversion was made, in accordance with a suggestion by Krieg[5], by assaying progeny of phage grown and irradiated in a non-selective host. The two r_{II} mutants, AP61 and AP156 (ref. 6), had been originally induced by 2-aminopurine. The host bacteria (*Escherichia coli* strain *Bb*) were grown with aeration to a concentration of 10^8/ml. in M9 medium[7] with added 0·05 per cent casamino acids. The cells were centrifuged, re-suspended at 10^9/ml. in M9 containing 0·0025 mgm. 1-tryptophan/ml. and 10^{-3} M sodium cyanide, and r_{II} virus was adsorbed at 37° C. for 3 min. This procedure yielded a mean multiplicity of seven viruses per bacterium. Cold medium was then added and the mixture was centrifuged in the cold to remove cyanide and most of the unattached phage. Less than 3 per cent of the cells were uninfected, as judged by colony counts. About 10^9 cells were re-suspended in a small volume of cold medium and added to 10 ml. of M9 aerated at 37° C. without tryptophan or casamino acids. Development of the complexes was stopped at the desired stage by rapid chilling. Before irradiation, the transmission of the infected cell suspension was adjusted to a minimum of 15 per cent by adding cold medium. 2-ml. samples at about 10° C. were irradiated at six different wave-lengths with a Hilger quartz prism monochromator. Intensities were measured and corrected for absorption as in previous work[4]. Following irradiation, 1 ml. of suspension was added to 8 ml. of M9 medium containing casamino acids. (Samples were removed and assayed for the number of infective centres. Each control mixture usually contained a total of around 6 × 10^7 infective centres. For the irradiated complexes the survival was usually no lower than about 25 per cent.) The mixtures were aerated for 2 hr. at 37° C. and treated with chloroform for complete lysis of bacteria. The progeny virus was plated on strain K, which permits plaque formation by wild-type but not r_{II} phage, and on strain B, which yields plaques from both.

Ultra-violet irradiation of extracellular phage can also induce mutations[8], including reversion of certain other r_{II} mutants[9]. In such experiments with AP156 (Fig. 2), the numbers of phage and bacteria used for attachment and final progeny growth were the same as in the experiments with irradiated complexes.

The progeny plaques on K from irradiated complexes were indistinguishable from wild-type. The ratio of final total phage to unirradiated infective centre counts was around 400, and this number was somewhat lower for irradiated complexes. The progeny from unirradiated complexes showed a ratio of revertant plaques on K to total plaques on B of about $2/10^8$ for AP156 and about $20/10^8$ for AP61.

The dose relation for reversion appears to be linear (Figs. 2 and 3) for different wave-lengths as well as for irradiation at various times in the latent period. This result may be interpreted to mean that a change in a single base causes a mutation, as has been suggested for the similar kinetics of chemical mutagenesis in T4 (ref. 10). The slope of each of these lines is a measure of sensitivity to reversion by radiation of the particular wave-length at a given time in the latent period.

A convenient way to compare two spectra is to plot their ratio as a function of wave-length. If the two spectra have the same shape, the points may be expected to fall on a straight line of zero slope. The deviation from such a line is an indication of lack of correspondence. The plots of the ratios in Fig. 4 show that the action spectra for reversion of the two mutants: (1) differ markedly from the absorption spectra of hydroxymethylcytosine (HMC) and adenosine; (2) differ less markedly from the absorption spectrum of guanosine and the action spectrum for killing; but (3) bear more resemblance to the thymidine absorption spectrum. The spread in the ratio is less than a factor of two for the thymidine comparison, but more than a factor of two (AP61) or three (AP156) for the comparison with killing. Unfortunately, the scatter in the mutation data is so great that one cannot

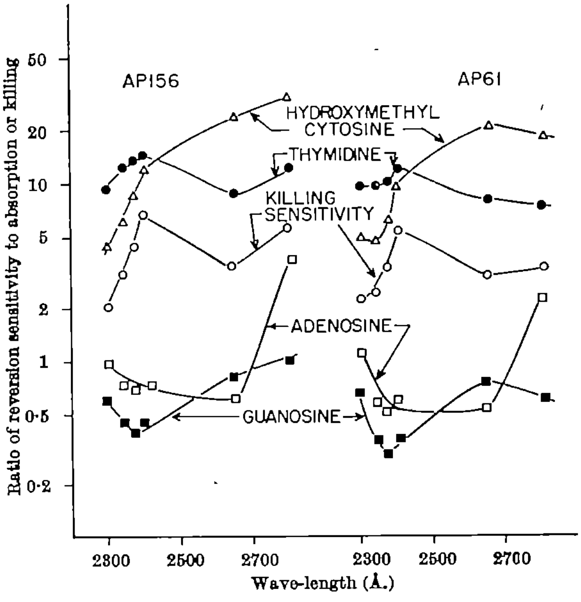

Fig. 4. Ratios of reversion action spectra to other spectra, in arbitrary units. Absorption data for *HMC* were kindly supplied by Dr. R. A. Deering. Absorption data for the other compounds at pH7 are taken from Beaven *et al.*[17]. Killing data are those of Fig 1

conclude that the reversion action spectrum is or is not the same shape as the thymidine absorption spectrum, although the coincidence is striking (Fig. 5). The data tend to support the hypothesis that these two mutants revert to apparent wild-type as a result of an ultra-violet-affected thymine in phage DNA.

Doudney and Haas[11] have proposed the theory that ultra-violet mutagenesis involves rather stable alteration of nucleic acid precursors in the bacterial cell. If alteration of nucleic acid precursors plays an important part in ultra-violet reversion of irradiated phage complexes, then one would expect to find little difference between the amount of reversion produced by irradiating the complexes just after phage DNA injection (time 0 in the latent period), when the phage has not yet had time either to use or to alter any of the available precursors, and the amount of reversion produced by irradiating the bacteria just before infection. However, reversion was highest at time 0 (Fig. 6). No reversion could be detected when the bacteria alone were irradiated (Fig. 2), in agreement with other results on irradiated starved bacteria[9]. The amount of reversion per unit of ultra-violet dose delivered to extracellular phage, where the precursor theory cannot apply, is not very different from the intracellular case (Fig. 6), an extraordinary coincidence if the mechanisms are entirely different. It is concluded that reversion by ultra-violet irradiation of both extra- and intra-cellular phage is the direct effect of alteration of viral DNA.

A mechanism for such mutagenesis is suggested by data on altered base incorporation after ultra-violet irradiation of primer in calf-thymus DNA-polymerase experiments[12]. The ultra-violet-produced dimerization of a *T–T* sequence at the mutant site of the viral primer might result in incorporation of another base instead of an adenine in the newly formed polynucleotide chain, perhaps because of a random base addition rather than the usual base pairing. In accordance with Freese's hypothesis that 2-aminopurine induces transitions[13], which are substitutions of one purine–pyrimidine pair for another, a reverse mutation in *AP*61 and *AP*156 would also require a transition. Thus a wild-type base sequence could result from a transition of a *T–A* base pair in *AP*61 and *AP*156 to an *HMC–G*.

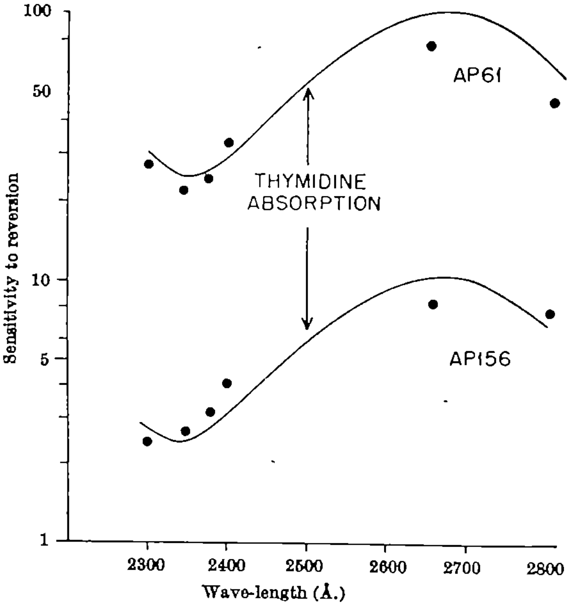

Fig. 5. Action spectra for reversion (points) compared with thymidine absorption (solid curve). Each point represents the slope of a line, such as in Fig. 3, corrected for change in photon energy with wave-length

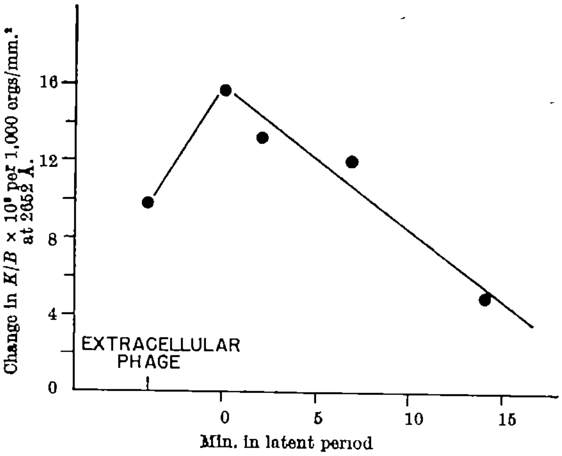

Fig. 6. Sensitivity to reversion of *AP*156 at different times during viral development. Each point represents the slope of a line in Fig. 2 or 3

Induced reversion of *AP*61 and *AP*156 has also been studied for a number of other mutagens. The amount of reversion of these mutants induced by hydroxylamine[14] and low *p*H[15] places them in the relatively unrevertible group of base-analogue induced mutants. The ethyl ethanesulphonate data[16] place *AP*156 in a medium category, and *AP*61 again in the low reversion group. However, in another study with the similar mutagen ethyl methanesulphonate[5], there is very little induced reversion in either *AP*61 or *AP*156. All these mutagenic agents are considered to induce transitions and to have their greatest effect on either *G* or *HMC*.

These results suggested that the forward and reverse mutations at the mutant site involved transitions between *A–T* and *G–HMC* pairs, but the tentative conclusion that the mutant gene contained the *A–T* pair was drawn from indirect evidence. The evidence from ultra-violet action spectra provides direct support for this hypothesis.

I thank Dr. Marvin Kastenbaum of the Mathematics Panel for fitting straight lines to the reversion data.

LETTERS TO THE EDITOR

RADIOPHYSICS

Radiation from Jupiter at 4·8 Mc./s.

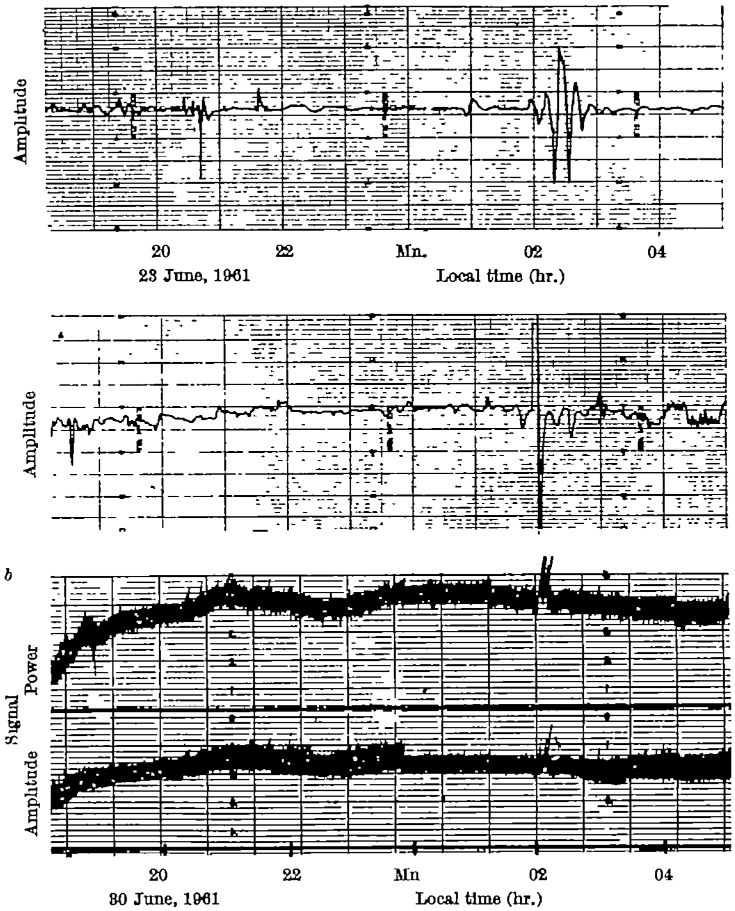
Early observations of the decametric radio emissions of Jupiter appeared to show that they had a narrow spectrum with a peak in the vicinity of 20 Mc./s. (refs. 1 and 2). As a result there were attempts to explain the radiation in terms of some appropriate single frequency mechanism such as plasma oscillations in a Jovian ionosphere[2]. More recently, however, with the passage of the solar activity maximum and consequent improving terrestrial observing conditions at low frequencies, the radiation has been detected at 10 Mc./s. (ref. 3). Here the results of observations at 4·8 Mc./s. will be reported.

They were made at Hobart, Tasmania, during June–August 1961. The equipment used was a phase-switching interferometer with an antenna primary beam 45° wide in the north–south direction and 12° wide east–west. The fringe spacing was 3°. The bandwidth of the receiver was 6 kc./s. There were three types of recorders. The phase-switching interferometer record was made with a post-detection time constant of 3 min. and hence averaged the shorter bursts of radiation. Records were made concurrently of the total signal power from both interferometer antennæ with a post-detection time constant of 0·2 sec. and of the total signal amplitude with a minimum recorder using time-constants of 0·1 sec. and 30 sec.

Identification of the Jupiter signals was made in all cases by inspection of the interferometer record. An average signal power of 10^{-24} W.m.$^{-2}$(c./s.)$^{-1}$ could positively be identified. Figs. 1*a* and *b* show sample records. There was frequently a fairly constant weak background signal on which the stronger bursts were superimposed. This is illustrated in Fig. 1*b*. The similarity of the three records of the burst in Fig. 1*b* indicates that it was essentially continuous without large variations of amplitude for several minutes. The peak intensity of the strongest bursts was 2×10^{-20} W.m.$^{-2}$(c./s.)$^{-1}$ while the average intensity of all bursts was 10^{-22} W.m.$^{-2}$(c./s.)$^{-1}$.

All observations were made at night when the ionospheric critical frequency f_0F_2 was in the vicinity of 2 Mc./s. Sporadic *E* and spread *F* ionospheric phenomena appeared on many occasions to be associated with the suppression of the interferometer records of cosmic radio sources. Assessed by the presence of these sources there were 40 nights of usable observations. On 29 of these Jupiter was recorded. Because some records were confused by transmitting station interference, this number should be regarded as a lower limit and it is considered likely that the Jupiter radiation was present on most nights.

Determination of the intensity spectrum of the radiation was difficult since very few observers have specified either the peak intensity or the average intensity of the bursts, but discuss instead the variation of the probability of their occurrence with frequency. However, the peak intensity recorded in the observations reported here did not differ significantly from the peak intensity of 10^{-19} W.m.$^{-2}$(c./s.)$^{-1}$ reported by Gardner and Shain[1] at 19·6 Mc./s., particularly when allowance is made for the fact that there was an interval of 5 years between the two observations. It seems likely, therefore, that the spectrum extends downwards in frequency below 4·8 Mc./s. possibly to much lower frequencies and is therefore not a narrow spectrum as had been thought earlier.



Figs. 1*a* and 1*b*. Sample records of Jupiter at 4·8 Mc./s. The interferometer records were made with an integration time of 3 min. The middle and lower records of Fig. 1*b* were made with a minimum recorder and with a simple integrator (time-constant 0 2 sec.) respectively

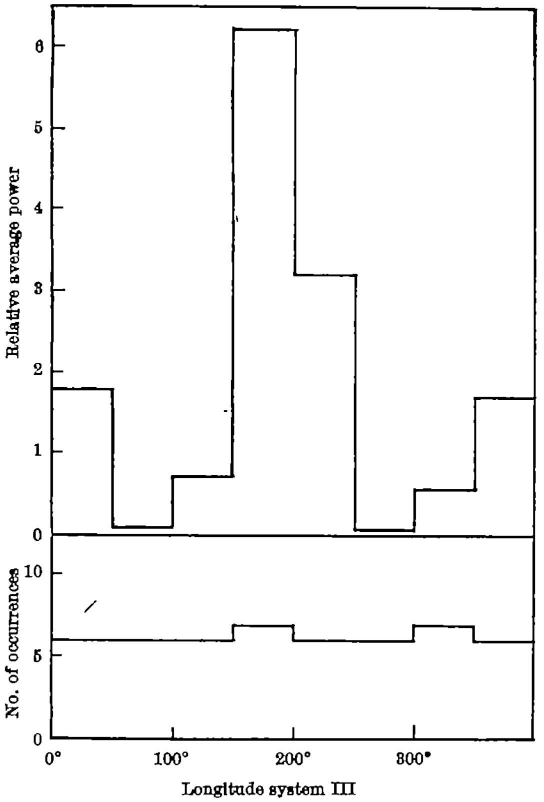


Fig. 2. Variation of the mean power of the 4·8 Mc./s. noise bursts and of the number of bursts with Jupiter longitude

When the probability of occurrence of the bursts was plotted as a function of Jupiter longitude very little variation was found, confirming the results of Carr *et al.*[3] at 10 Mc./s. However, as shown in Fig. 2 there was a pronounced variation in their average intensity with longitude. Using Longitude System III proposed by Smith and Carr[2] with a rotational period of 9 hr. 55 min. 28·8 sec. the two maxima occurred between 150° and 250° and between 000° and 050°. The former of these corresponds with the peak in the probability of occurrence found by Shain[4] in his 1951 records.

These results indicate that at least at the lower frequencies the average burst intensity is a much more powerful indicator of the variation of the radiation with the planet's rotation than is the probability of occurrence used by other investigators.

The existence of two peaks with a longitude separation of about 180° suggests that the radiation is associated with a Jovian magnetic field the axis of which is inclined to the rotational axis. It might be expected, if this were so, that the polarization of the radiation would be of opposite sign at the longitudes of the two maxima.

This work is partly financed by a grant from the Australian Radio Research Board.

ASTROPHYSICS

Distribution of Elements over the Surface of a Magnetic Star

The anomalous abundances observed in magnetic stars have been attributed to nuclear processes occurring in hot spots in the surface layers. Induced electric fields set up by changes in the magnetic field with time are assumed to heat the spots and thus provide the reacting particles with sufficiently high energy[1]. Both in the magnetic stars and in the related spectrum variables the equivalent widths of certain classes of lines show periodic variations with time. On the oblique rotator model this is interpreted as an aspect effect, corresponding to a 'patchy' distribution of elements over the stellar surface[2]. It does not appear easy to account for this uneven distribution on the hypothesis of surface reactions alone.

There is, however, another effect which, under favourable conditions, might lead to or preserve such a distribution. In a magnetic field, B, that is not strictly homogeneous, each atom and ion is acted on by a force, $\mu\nabla B$, along the field lines. The magnetic moment, μ, is equal to the product of Bohr's magneton, μ_B ($0{\cdot}927 \times 10^{-20}$ erg. gauss^{-1}), the magnetic quantum number, M, and Landé's g-factor.

In the case of the rare-earth elements, which is the group showing the most striking non-uniform distribution in the magnetic stars, the magnetic moments are particularly large. Due to the only partly filled N- and O-shells of these atoms all stages of ionization that may exist in stellar atmospheres have large magnetic moments. In the case of the neutral atoms of europium, samarium and gadolinium, for example, the configurations of the ground-states are ^8S, ^7F and ^9D respectively.

The corresponding maximum magnetic moments in terms of $\mu_B g$ are 3½ for the first one and 6 for the last two. Comparable values for the magnetic moments are found in the iron group, the elements of which also show variations in line strength in magnetic stars. The value of the magnetic moment which is most important for the distribution of a particular element is clearly that corresponding to the stage of ionization which is dominating in the region considered. This mechanism will only work in the atmospheres of the stars where the alignment of the particles is not too much disturbed by collisions.

We may make an estimate of the order of magnitude of the forces involved and of the resulting scale in the density distribution. The maximum observed field strength in a magnetic star runs as high as $3{\cdot}4 \times 10^4$ gauss[3]. This is the field integrated over the stellar surface so it does not seem unreasonable to assume that the actual field strength in local regions may exceed this average value by one order of magnitude. Assuming a field strength of 10^5 gauss and a characteristic length determining the gradient in the magnetic field of 10^9 cm., the magnetic force amounts to 10^{-3}–10^{-2} of the weight of the particles. If we further assume that the lines of force are roughly horizontal, the equilibrium equation is:

$$\nabla n/n = \mu\nabla B/kT \sim 1/L$$

where n is the partial density. Taking $T \sim 10^4$ we obtain $L \sim 10^{12}$ cm., which is of the order of magnitude of the radius of an A-star.

Even in the photospheric layers a net paramagnetic moment will result, since the Zeeman levels are here populated according to Boltzmann's Law.

For this mechanism to work the magnetic field should not change too violently with time. With the oblique rotator model the intrinsic changes in the field come out relatively small. If this model is representative the mechanism described here may well play an important part in determining the distribution of elements in the atmospheres of the magnetic stars.

PHYSICS

Cæsium-137 in the Seas off the Cape of Good Hope

MEASUREMENTS of fall-out cæsium-137 in surface sea-water in the northern hemisphere have been reported by two groups of workers[1,2]. With the view of obtaining an estimate of the fall-out contamination in the southern oceans, a programme of cæsium-137 determination in the waters off the Cape of Good Hope was begun in July 1961 in collaboration with the Oceanography Department of this University. Samples were collected by the University of Cape Town research vessel, the *John D. Gilchrist*, and five had been obtained by the middle of September 1961. At this stage the recent series of Russian nuclear tests was in progress, and it was decided to extend the programme on a semi-permanent basis. This communication provides an estimate (based unfortunately on a limited number of samples) of the cæsium-137 level in sea-water in southern latitudes due to earlier (pre-1961) nuclear explosions.

Our detection techniques in general followed those of Folsom *et al.*[2]. Thus we collected 200-litre samples in polythene drums, and we used the extremely simple and effective method of cæsium co-precipitation with potassium by the addition of sodium cobaltinitrite to the sea-water in the drums. Further, we detected the 0·66-MeV. γ-ray of cæsium-137 utilizing a large (4-in.) sodium iodide (thallium) low-background crystal assembly. In our case[2], however, only a two-channel and not a multichannel pulse height analyser was available. We accordingly thought it desirable to perform further chemical reactions to remove potassium from the precipitate. The following procedure as recommended by Sugihara *et al.*[3] was used. The precipitate was dissolved in 6 *N* hydrochloric acid, the solution filtered, and 1 gm. cæsium chloride and 60 gm. dodecatungstosilicic acid were added. The solution was heated on a water-bath for 1 hr. before being allowed to stand overnight. The resultant cæsium silicotungstate precipitate was then well washed by successively slurrying up with hydrochloric acid and distilled water, and decanting the supernate after the precipitate had settled. This was repeated until the supernate was free of the pink colour from the original hydrochloric acid solution, and the precipitate was then transferred to a standard polythene bottle for counting. The size of precipitate obtained from the original 200-litre sea-water sample was about 10 c.c.; trial experiments with tracer cæsium-137 showed that it contained 74 ± 7 per cent of the cæsium in the sea-water. This yield was independent of the temperature of the sea-water during the cobaltinitrite precipitation process provided this temperature was kept below 19° C. The sample as counted was virtually free of potassium, thus reducing the predominant source of interference when performing γ-spectrometry in the cæsium channel. Possible sources of interference from other radioactive isotopes were considered by Mohanrao and Folsom (private communication), who concluded that they were likely to be negligible. To check the efficacy of the tungstosilicic acid stage of our chemistry, and to guard in general against possible sources of contamination giving γ-rays of a higher energy than that from cæsium-137, we used the second channel of our double channel spectrometer to monitor an energy window just above the cæsium-137 0·660-MeV. peak. Counts in this channel were found to be on the average only 3 per cent of those in the cæsium peak, and were never higher than 12 per cent for any of the samples tested by us. The additional stage in the chemical process would thus appear to be fulfilling its purpose.

Table 1

Sample	Date collected	Position	Distance from coast (miles)	^{137}Cs (μμc./kl.)
1	8/8/61	Off Cape Point	7	161
2	14/8/61	36° 22′ S., 21° 27′ E.	139	87
3	26/8/61	34° 38′ S., 18° 38′ E.	12	92
4	13/9/61	34° 23′ S., 17° 50′ E.	28	29
5	13/9/61	34° 23′ S., 17° 50′ E.	28	79

The results are presented in Table 1. Each individual determination has a 95 per cent confidence limit of ± 25 μμc./kl. This is the error due to counting statistics alone, which in general dwarfs the other sources of error due to variations in the chemical yield and uncertainties in the calibration process. The cæsium-137 content of the waters around Cape Town just prior to the 1961 nuclear tests was calculated on the basis of our five samples to be 90 ± 47 μμc./kl. This is to be compared with the values of 138 ± 40 μμc./kl. obtained off the coast of California during 1959–60 by Folsom *et al.*[2], and 380 ± 136 μμc./kl. obtained in 1959 by Yamagata[1] in Japanese waters. The level of contamination in the ocean would thus appear to be lower in the southern than in the northern hemisphere. This is, of course, to be expected from general fall-out measurements[4]. It will be of interest to follow the cæsium-137 level over the next few years; to this end, we are continuing to collect samples at regular intervals.

We thank Messrs. P. van Reenen and J. Engelbrecht for help in collecting our samples. Financial aid was given by the University of Cape Town Oceanography Department and the South African Atomic Energy Board. We thank Dr. R. Arnold and Dr. R. Edge for advice on chemical matters, and Dr. T. R. Folsom for supplying us with details of his chemical methods prior to publication.

Some Consequences of Ion Slip in a Plasma flowing through a Magnetic Field

Direct generation of electrical power can be achieved by driving a conducting gas through a magnetic field transverse to the direction of flow. The necessary conductivity is obtained by heating the gas to a temperature at which appreciable thermal ionization occurs, the latter in accordance with the Saha equation. The conducting gas will be considered to consist of neutral particles and charged particles, no distinction being made between ions and electrons. It is the purpose of this communication to discuss the behaviour of this system as it flows along a duct (neglecting wall effects) through a uniform transverse magnetic field as shown in Fig. 1.

In region 1 the various particle species have a common flow velocity, V_f. In region 2 the respective flow velocities of neutrals and charged particles are V_{fn} and V_{fc}. If no collisions occurred and provided that the Larmor radii were very much less than the field dimensions the charged particles within the field would gyrate about the magnetic field lines and their flow velocity through the field would be zero. However, collisions result in momentum transfer between the neutral particles and the charged particles to produce the flow velocity V_{fc}. If slip of charged particles with respect to the neutrals is present, V_f is not the velocity to use in calculating the electric field induced by the flow of charged particles. Unfortunately, the data to calculate V_{fc} are not available but a discussion of some of the consequences of the fact that V_{fc} is less than V_f may be useful.

In region 1 an equilibrium condition exists between thermal ionization and recombination events. When the flow enters region 2 the charged particles present in the system cannot penetrate the magnetic field to a distance greater than their Larmor radii unless momentum transfer collisions with neutrals occur. The result is that a region of increased charged particle density is created at the magnetic field boundary between regions 1 and 2 and is continuously replenished by charged particles from the flowing system. The loss processes operative in this region of enhanced ionization are diffusion into regions 1 and 2, recombination, and flow into region 2 to produce an increased charged particle density as indicated in Fig. 2. When the flow leaves region 2 and enters 3 a decrease in charged particle density occurs.

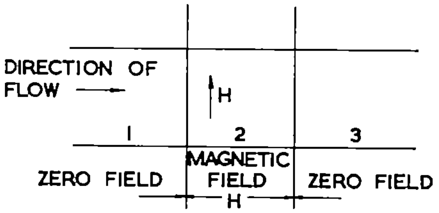

Fig. 1. Regions considered in flow through a uniform transverse magnetic field

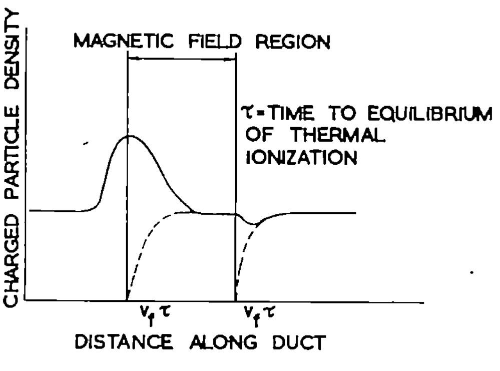

Fig. 2. Variation in charged particle density produced when plasma flows through a magnetic field region

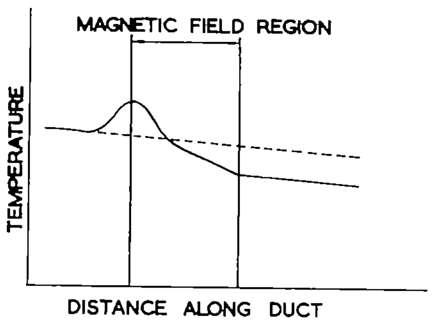

Fig. 3. Variation of temperature along duct

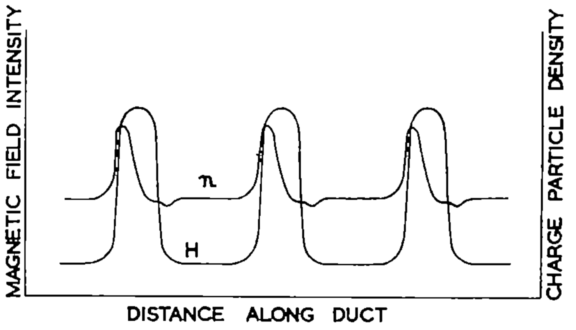

Fig. 4. Suggested non-uniform magnetic field designed to increase the local density of charged particles

Consider a slab of gas flowing through the three regions; when the charged particles are removed by the magnetic field, the ionization energy is also removed, and thus the region of increased charged particle density also becomes one of increased temperature when the ionization energy is released during the recombination processes. As the slab moves through the magnetic field, the continuous removal of charged particles progressively cools the gas. The temperature distribution along the duct resulting from this process is shown in Fig. 3.

The charged particle flow velocity is produced by collisions which displace the centres of gyration, and the charged particles progress through the magnetic field in a series of arcs of the Larmor radii r_L rather than the trajectories characteristic of a field-free system. Consequently, V_{fc} is a function of r_L and the collision frequency ν_c appropriate to the species in a magnetic field. Since $r_L \propto 1/H$ and since ν_c is probably dependent on H, it is clear that the usual assumption that the electric field induced by the charge flow is a linear function of H is unlikely to be valid.

It has been shown that an increased charged particle density may be anticipated when a flowing plasma enters a magnetic field. It may be possible to increase the power output of a d.c. electrical power generator based on magnetoplasmadynamic principles by using a non-uniform magnetic field as shown in Fig. 4 instead of the more conventional uniform field. Such a field would be designed to produce and take advantage of the predicted increased charged particle density.

Vacuum Ultra-Violet Absorption Spectra of Flash-heated Lead reacting with Various Gases

Recent investigations of the hot atom chemistry of lead-212 recoiling from α-decay of polonium-216 have shown that energetic lead atoms can react with gases such as methane to form volatile compounds[1]. In the recoil reactions, the lead species originate with high kinetic energy and are afterwards degraded by collisions, eventually reacting to form stable compounds.

In an effort to determine whether gaseous lead atoms could react at essentially thermal energies (<1 eV.) to give products similar to those observed in the recoil studies, the present investigations were undertaken.

The techniques of flash heating lend themselves ideally to the study of thermalized metal atoms in the gas phase because of the ability to vaporize fairly significant quantities of material in the presence of a surrounding medium that is only slightly heated[2]. Combination of flash heating with kinetic absorption spectroscopy allows the detection and examination of short-lived species in the vapour-phase during the reaction[3].

Using the techniques previously described[3], about 8 or 10 mgm. of lead was vaporized per flash. The metallic lead in the form of a thin ribbon (0·0005 in. thick, 1/8 in. wide) was wound on a quartz support so as to pass through the optical path within the cell and replaced the carbon grids used in the earlier work.

The usual spectral region photographed extended from 1300 to 3300 Å. This region includes the Rydberg series leading to the ionization limit of PbI at 1671·65 Å., corresponding to transitions from the ground-state ($6p^2\ {}^3P_0$) (ref. 4).

All spectra taken within a few milliseconds after the beginning of the preparative photoflash showed absorption lines due to lead atoms in the ground-state. Transitions from the first and second excited states were also observed. These lie 7,819·35 and 10,650·47 cm.$^{-1}$, respectively, above the ground-state and correspond to the configurations $6p^2\ {}^3P_1$ and $6p^2\ {}^3P_2$ (ref. 4). No evidence for ionization of the vaporized lead was obtained.

Reactions of lead vaporized in the presence of CF_4 or SF_6 resulted entirely in fluorine abstraction from the parent fluorinated molecule by the metal atoms, yielding lead monofluoride. The monofluoride was identified from the band systems near 2100, 2500 and 2800 Å.[5,6]. The PbF could be observed from the time of maximum light intensity until about 700μ later. After this period, light scattered by particles formed by further reaction of PbF caused a heavy continuous absorption and prevented subsequent spectral observations. Many new vibrational bands and an apparently new system in the 1800–1900 Å. region have been observed in association with PbF in these studies. Rotational fine structure was clearly observed, particularly in the 2800 Å. region.

Table 1. Species Observed by Flash Heating and Kinetic Spectroscopy of Lead in Various Gases

Short-lived atom or molecule	Gaseous matrix	*Delay times (μs.)	Wave-lengths (Å.)
Pb ($6p^2\ {}^3P_{0,1,2}$)	All	0–1300	1600–3300
Pb	,,	,,	bands at 2136, 2143, 2161, 2167
PbF	SF_6 CF_4	0–1050	band systems at 1900, 2100, 2500, 2800
PbO	CD_4+air	45–1000	band systems from 2800 to 3700
Unidentified	O_2 C_2H_6 CH_4 D_2 (2900 Å. only)	180–420	band systems at 2400, 2900
CO (excited)	CO	1000	1700
O_2 (excited)	O_2	180	2000–2500
Emission lines	vacuum SF_6 CF_4 Ar CO	0–1000	1587, 1634, 1661

*Delay times refer to time elapsed between peak intensity of preparative flash and peak intensity of spectroscopic flash.

PbO was produced by reactions of flash-heated lead with oxygen or with air present as an impurity in methane. Band systems for PbO lie mostly in the wave-length regions above 2800 Å. (ref. 5).

In the presence of methane or ethane, unidentified diffuse transient systems were observed in the regions near 2400 and 2900 Å. The system at 2900 Å. was faintly visible when the flash heating was carried out in a deuterium atmosphere, indicating a possible hydride formation.

Since it was desired to limit these studies as much as possible to thermally initiated reactions, gases were chosen so as to be transparent to the light used and to minimize photochemical processes. Table 1 summarizes the gases used and the absorptions observed at various delay times following peak intensity of the preparative flash.

Of special interest are the diffuse bands observed at 2136, 2143, 2161 and 2167 Å. These occurred in all the gases and in vacuum and have tentatively been assigned to the $Pb_{2(g)}$ molecule.

The absorption spectra were supported by mass spectrographic analyses in showing that no volatile compounds analogous to those reported for the recoil lead-212 studies[1] were produced by reactions in methane, methane and air, carbon monoxide or argon.

Complete analyses of the spectra are in progress in an effort to determine electronic temperatures of the vaporized lead atoms and vibrational and rotational temperatures of the product molecules. Additional efforts are being made to identify the emission lines (Table 1) and the unidentified systems near 2400 and 2900 Å.

Prevention of Uptake of Strontium Ions on Glass

THE uptake of metal ions by the walls of glass vessels is a frequently encountered phenomenon in analytical chemistry and radiochemistry, and is responsible for the difficulty of maintaining dilute solutions at a known concentration during storage. In general this problem is overcome by making such solutions acid. and neutralizing immediately before use. This technique is not applicable, however, when it is necessary to use the same solution at neutral *p*H for long periods of time.

We have been investigating the uptake, by bone, of strontium ions (labelled with strontium-89) at approximately physiological *p*H (7·3), and here the effect of uptake by the walls of the glass tubes used is quite serious. Attempts were made to overcome this by using polythene tubes; but these were found to be even less suitable than glass.

The difficulty has been overcome by coating the inside surfaces of the glass tubes with a non-adsorbent material—a proprietary polyester resin. Though this is satisfactory in preventing uptake, the vigorous shaking required for our experiments caused breakdown of the coating after 60–70 hr. The life of the coating can be extended by first coating the glass tubes with vinyltrichlorosilane and then with the polyester resin. Coating surfaces with non-adsorbent materials has already been investigated for the purpose of easing the decontamination of active surfaces[1,2]; but there appears to have been no application of this to the prevention of uptake in reaction vessels.

Labelled solutions of strontium chloride (*p*H ~ 7) were vigorously shaken for 24 hr. in tubes of the following materials: (*A*) glass, (*B*) polythene, (*C*) glass coated with polyester resin, (*D*) glass coated first with vinyltrichlorosilane and then polyester resin.

Afterwards, an assay was made of the radioactivity remaining in solution. Table 1 shows the percentage uptake for each series at varying concentrations of metal ion. The number of tubes examined is shown in parentheses.

Table 1

$[Sr^{2+}]$ (moles/l.)	*A*	*B*	*C*	*D*
1×10^{-3}	12 ± 8 (8 tubes)	66 ± 6 (6 tubes)	0 (36 tubes)	1 (12 tubes)
1×10^{-6}				0 (6 tubes)
Carrier-free ^{89}Sr	15 (5 tubes)		7 (10 tubes)	8 (12 tubes)

Within the limits of experimental error the results show that polyethylene is quite unsuitable, but that the use of this coating introduces a significant improvement compared with glass.

The use of this, or other similar coatings, was suggested by Mr. J. R Morris of this Establishment, and may be applicable to other systems of metal ions.

We thank the U.K. Atomic Energy Authority for permission to publish this communication.

[2] Tompkins, P. C , and Bizzell, O M., *Indust Eng. Chem.*, 42, 1469, 1475 (1950).

THE finding that polyethylene adsorbs about five times as much strontium-89 as does glass is rather unexpected considering that in the case of glass, possible adsorption mechanisms include powerful ion exchange processes, while with polyethylene the possible mode of attachment is not evident. On this finding the widespread use of polyethylene instead of glass or ceramics for radioactive effluent tank linings, pipelines, etc., could conceivably lead to a build-up of activity if conditions of *p*H were suitable.

The assumption by Boocock *et al.* that the strontium-89 is in ionic form may not be justified. At the physiological *p*H of 7·3 it is not unlikely that the strontium is partially, at least, in the form of a radiocolloid of strontium hydroxide, the adsorption mechanism for which is dependent on interfacial zeta potential, rather than ionic bonding.

It is hoped that the authors can improve further the adhesion of their polyester film, as the technique might well greatly ease the problems of the decontamination of vessels or equipment which have been in contact with radioactive solutions.

CHEMISTRY

Isotope Effects in the Infra-red Spectrum of 1-^{13}C-Propene-1

THE abundance and location of isotopically labelled carbon atoms have been investigated by numerous techniques, but no use has been reported of vibrational spectra for this purpose. This communication describes how the infra-red spectrum of a sample of propene prepared with carbon-13 is consistent with all the labelled isotope being in the 1-position.

The sample was prepared from barium carbonate enriched with 55 per cent carbon-13, using a modification of the method of Fries and Calvin[1]. These authors provide radiochemical evidence for the specific preparation of 1-^{14}C-propene-1 by this route. Analysis by mass spectroscopy gave good value for the percentage enrichment but it could not locate the carbon-13 with certainty. There seemed to be rearrangement in the ionization chamber, possibly due to the formation of a cyclic intermediate. The use of nuclear magnetic resonance spectra in the examination of carbon-13 resonances in a variety of organic compounds has been discussed by Lauterbur[2]. However, insufficient sample was available for a nuclear magnetic resonance investigation in the present work.

The infra-red spectrum of a labelled propene sample at 32 mm. mercury pressure in a 9·5 cm. single path cell was recorded between 400 and 3,650 cm.$^{-1}$ on a Unicam *SP*100 spectrometer fitted with the *SP*130 grating accessory. The quantity of sample used was 2·4 mgm. The spectrum differs from unlabelled propene in two respects: first the C=C stretching frequency at 1,652 cm.$^{-1}$ is decreased by approximately 10 cm.$^{-1}$; secondly, the out-of-plane frequency at 912·3 cm.$^{-1}$ is shifted to 903·6 cm.$^{-1}$.

A shift in the C=C stretching frequency can arise from a labelled carbon atom in either the 1- or 2-position. Unfortunately the precise shift and the relative strengths of the carbon-13 and carbon-12

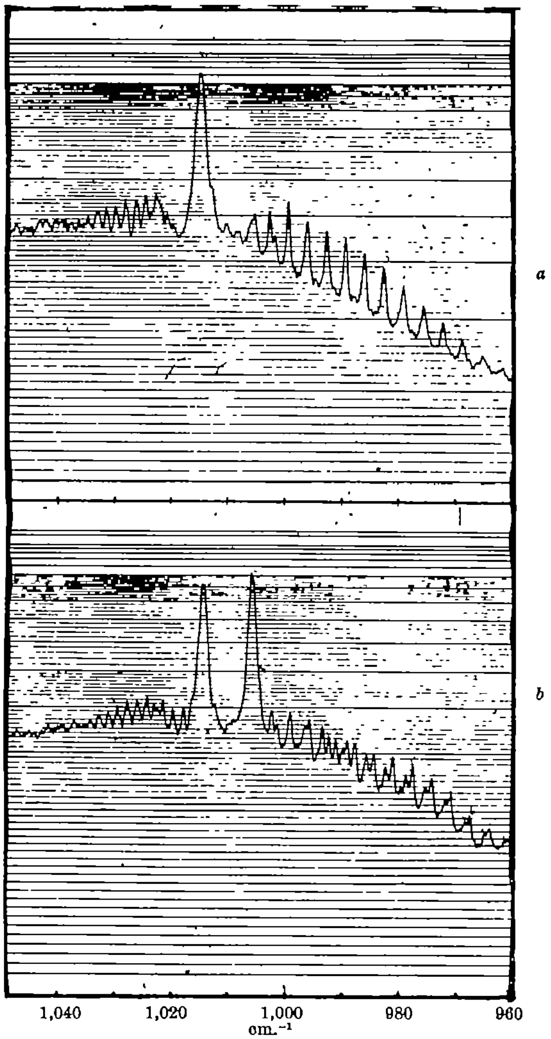

Fig. 1. Methylene wagging mode. *a*, Propene; *b*, labelled propene

components are difficult to measure owing to the complex PQR structure of this hybrid parallel-pendicular band.

The 912·3 cm.$^{-1}$ band has usually been assigned to an out-of-plane deformation of the hydrogen atoms of the $=CH_2$ group[3]. On this simple picture a change in the mass of the 1-carbon atom would not be expected to affect the frequency of this mode. However, a recent normal co-ordinate analysis of out-of-plane vinyl modes by Scherer and Potts[4] describes this as a methylene wagging mode in which the 1-carbon atom participates appreciably.

The spectrum of the methylene wagging frequency for propene and labelled propene is shown in Figs. 1*a* and *b*. The shifted band at 903·6 cm.$^{-1}$ implies that the carbon-13 is in the 1-position; furthermore, the measured strength of this absorption shows that 55 per cent of the propene is in this form. This correspondence with the enrichment ratio of the starting material proves that all the labelled carbon is in the 1-position.

The rotational fine structure of the 903·6 cm.$^{-1}$ carbon-13 methylene wagging mode shows some measurable differences from the corresponding 912·3 cm.$^{-1}$ carbon-12 band. These differences and the shifts in fundamental frequencies with isotopic substitution are at present being investigated theoretically for propene and some simple related molecules.

I thank Mr. G. Gough for the mass spectroscopic data and Dr. C. C. McCain for making this compound available.

Oxygen Adsorption and the Magnetic Susceptibility of Ice at Low Temperatures

When dealing with the magnetic susceptibility of tumour tissue[1], we reported the magnetic susceptibility of ice at various temperatures from 273° K. down to 77° K. Since this publication, the authors have made many susceptibility measurements of ice, using the same equipment, and have obtained similar results, that is, a relatively large increase in diamagnetism below 150° K. Normal diamagnetism is not dependent on temperature, and hence further experiments were made of the magnetic susceptibility of ice at low temperatures in an attempt to determine some extraneous cause of the increased diamagnetism.

In the work reported in ref. 1 the ice was prepared by immersion of distilled water in liquid nitrogen. Both the weight and the magnetic susceptibility were measured on the same quartz helical spring balance[2]. Just prior to making the measurements, the balance case was flushed out with helium using a flow method, and the system was sealed at atmospheric pressure. The specimen was then cooled to 77° K., and measurements were taken as the temperature was raised to 235° K.

Recent tests using the system under a slight positive pressure revealed a small leak in a faulty thermocouple seal, which allowed a small amount of air into the balance. By using a new leak-free system, about 0·01 atmosphere of oxygen was admitted into the helium atmosphere, and this resulted in a marked increase in the diamagnetism when the sample was cooled to about 100° K. The oxygen in the small amount of air which leaked into the system was adsorbed on to the ice below 150° K. The fact that the oxygen increased the diamagnetism shows that the phenomenon is one of chemical adsorption[3]. Additional investigations of the adsorption of oxygen on ice at low temperatures are being made to show the role of oxygen in the previous tumour measurements.

After determining the cause of the anomalous diamagnetism of ice, the true magnetic susceptibility of ice at low temperatures was determined. Although there are several recorded measurements[4–6], no other measurements appear to have been made below about 220° K. Thus, the magnetic susceptibility of ice was remeasured, using the following technique. A drop of approximately 16 mgm. of deionized distilled water was suspended from the quartz helix by a very fine 'Pyrex' loop. The balance case was flushed and filled with helium, and the specimen was frozen by passing liquid nitrogen

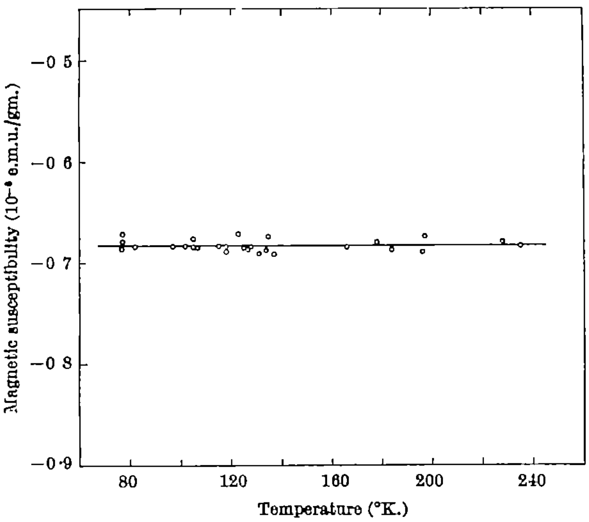

Fig. 1. Magnetic susceptibility of ice as a function of temperature

under pressure through a double-wall jacket of the balance case. With the specimen at 77° K., the sample chamber was evacuated and refilled with helium to ensure the removal of all oxygen. Susceptibility measurements taken at different temperatures for six different specimens of ice are shown in Fig. 1. The mean value for the magnetic susceptibility of ice is:

$$(-0{\cdot}683 \pm 0{\cdot}001) \times 10^{-6}\,\text{e.m.u./gm. from } 77°\text{ K. to } 235°\text{ K.}$$

Relation between Partition Coefficients and Properties of Solvents

PUBLISHED data on the partition of non-electrolytes between water and different organic solvents are abundant; but no successful attempt has been made to correlate the partition coefficients with the properties of solvents. No macroscopic property such as dielectric constant, refractive index or dipole moment can be correlated with partition coefficients in a simple manner. I have found the correlation between Hildebrand's solubility parameters of solvents and partition coefficients to be the most satisfactory.

The partition coefficient of a solute z corrected, if necessary, for dissociation in aqueous phase, extrapolated to infinite dilution, and expressed in mole fraction units $({}^{x}k^{\infty}_{z})$, is simply related to standard chemical potentials (μ^{θ}_{z}) of the solute in both phases, namely: $-RT \ln {}^{x}k^{\infty}_{z} = \mu^{\theta}_{z(i)} - \mu^{\theta}_{z(H_2O)} \equiv \Delta\mu^{\theta}_{z}$. In Fig. 1 $\Delta\mu^{\theta}_{z}$ for acetic acid[1] (I), acetone[2] (II) and *o*-nitro-aniline[3] (III) are plotted against solubility parameters[4] (δ_i) of the solvents listed below Fig. 1. As can be seen, the experimental points clearly follow two different curves, which in Fig. 1 are denoted by numbers 1 and 2. The curves of type 1 have been calculated by the following equation:

$$\Delta\mu^{\theta}_{z} = v^{0}_{z}\,(\delta_z - \delta_i)^2 + C_z \qquad (1)$$

where v^{0}_{z} and δ_z are the molar volume and solubility parameter of the solute, respectively, and C_z is a constant. In deriving equation (1), two assumptions on the thermodynamic properties of the organic phase are made: 1° $\lim\limits_{x_z \to 0} \dfrac{\partial s^E}{\partial x_z}$ is independent of the solvent, and 2° $\lim\limits_{x_z \to 0} \dfrac{\partial h^E}{\partial x_z}$ may be calculated by the Hildebrand–Scatchard equation.

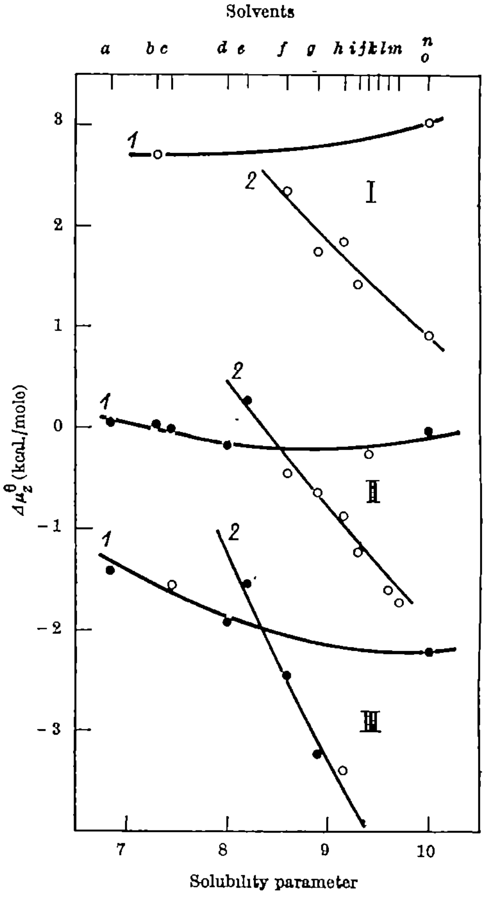

Fig 1. Plot of $\Delta\mu^{\theta}_{z} = -RT \ln {}^{x}k^{\infty}_{z}$, for acetic acid (I), acetone (II) and *o*-nitroaniline (III), versus solubility parameter of *a*, isooctane; *b*, *n*-hexane; *c*, *n*-heptane; *d*, hexadecane; *e*, *cyclo*hexane; *f*, carbon tetrachloride; *g*, toluene; *h*, benzene; *i*, chloroform, *j*, tetrachloro-ethylene; *k*, chlorobenzene; *l*, 1,1,2-trichloroethane; *m*, 1,1,2,2-tetrachloroethane; *n*, carbon disulphide and *o*, nitrobenzene. Curves 1 and 2 are calculated from equations (1) and (2), respectively, with the following values of the parameters: $v^{0}_{\text{I}} = 0{\cdot}0575$, $\delta_{\text{I}} = 7{\cdot}60$, $C_{\text{I}} = 2{\cdot}70$; $v^{0}_{\text{II}} = 0{\cdot}0785$, $\delta_{\text{II}} = 8{\cdot}80$, $C_{\text{II}} = -0{\cdot}19$, and $v^{0}_{\text{III}} = 0{\cdot}106$, $\delta_{\text{III}} = 9{\cdot}75$, $C_{\text{III}} = -2{\cdot}20$. $v^{0}_{\text{I}*} = 0{\cdot}061$, $\delta_{\text{I}*} = 17{\cdot}26$; $v^{0}_{\text{II}*} = 0{\cdot}085$, $\delta_{\text{II}*} = 15{\cdot}87$, and $v^{0}_{\text{III}*} = 0{\cdot}144$, $\delta_{\text{III}*} = 15{\cdot}42$. ○, Published data; ●, own measurements

The extension of these assumptions to the aqueous phase as well leads to the following equation:

$$\Delta\mu^{\theta}_{z*} = v^{0}_{z*}\,(23\cdot4 - \delta_{l})\,(2\delta_{z*} - \delta_{l} - 23\cdot4) \qquad (2)$$

where 23·4 is the solubility parameter of water. The curves of type 2 agree well with equation (2). The constants v^{0}_{z*} and δ_{z*} of equation (2) can be calculated easily, since this equation divided by $(23\cdot4 - \delta_{l})$ gives an equation linear in δ_{l}. Experimental values of v^{0}_{z*} are larger than the molar volumes of pure solutes, v^{0}_{z}, and δ_{z*} are larger than δ_{z} in equation (1).

The observed dual behaviour of the solute, depending on the organic solvent, seems to be quite general, and is not restricted to the solutes described here. Many other substances, such as formic and propionic acids, phenol and nitrophenols, aniline, *m*- and *p*-nitroaniline, *o*-, *m*-, and *p*-toluidine, nitropropane and nicotine, behave in a similar manner. The appearance of the two curves of partition for each solute is probably due to a difference in the degree of hydration of the solute molecules. In solvents with rod-like molecules (as aliphatic hydrocarbons or carbon disulphide) the curves of type 1 are characteristic, for the non-hydrated molecules probably predominate, whereas in other solvents the degree of hydration is high.

I thank Prof. Wiktor Kemula for advice.

Tri*cyclo*quinazoline and Combustion Products

Tri*cyclo*quinazoline (TCQ), which can be produced by the pyrolysis of methyl anthranilate, is a stable compound which has been shown to be carcinogenic[1,2]. Since methyl anthranilate is present in plants[3], there was therefore good reason to look for TCQ in the products of combustion of fuels derived from vegetation.

From a sample of pure TCQ, kindly given by Prof. G. T. Cunningham (Royal College of Surgeons), its ultra-violet and fluorescent spectra were determined (see Figs. 1 and 2), and it was by these characteristics that its presence was sought in samples of particulate matter which pollutes urban air. The samples were collected by filtration or electrostatic precipitation.

Four samples were examined: one was of pure coal smoke collected from an experimental chimney; two were of air solids collected on the roof of St. Bartholomew's Hospital and from the air-conditioned filter of the Royal Festival Hall; another was from the air in the Rotherhithe Tunnel, which is polluted by the exhausts of petrol and Diesel traffic. Because the amounts and nature of the samples varied there were minor variations in the techniques of analysis; but the following account gives the essential details.

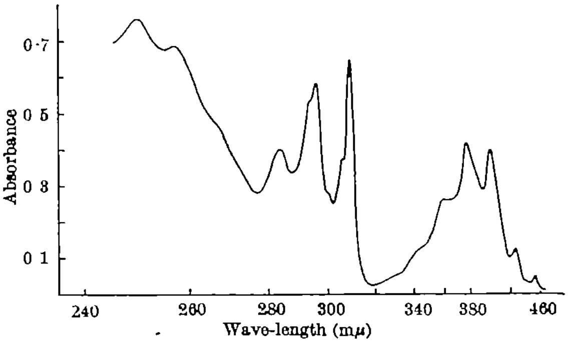

Fig. 1. Absorption spectrum of tri*cyclo*quinazoline in *cyclo*hexane. (Concentration, 4 3 μgm./ml.)

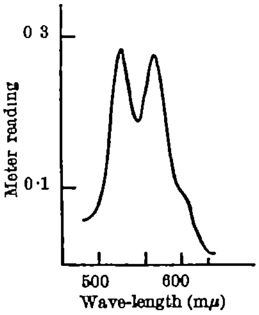

Fig. 2. Fluorescence spectrum of tri*cyclo*quinazoline in *cyclo*hexane (Concentration, 4 3 μgm./ml.)

5 gm. of collected air solids were extracted with hot benzene for 14 hr. The extract was shaken with caustic soda, acid and water in sequence to remove unwanted material. The benzene solution was then distilled to small bulk, divided into two equal portions, and one portion labelled with about 0·2 mgm. of TCQ.

Two chromatographic columns were prepared from a slurry of *cyclo*hexane and partially deactivated alumina. The two portions of the extract were separated on the columns, which were developed initially with *cyclo*hexane and then with benzene. The position of TCQ in the labelled column could be seen as a pale yellow-green fluorescent band and the fractions eluted which contained TCQ could be found by looking for an absorption peak at 310 mμ. The corresponding fractions in the test column did not indicate the presence of TCQ. The TCQ from the labelled column and the corresponding fractions in the second column were each separately bulked. M. W. Partridge (private communication) found the TCQ was little affected by treatment with hot alkaline potassium permanganate and this property of the compound was exploited to enable the removal by oxidation of other compounds present in the same chromatographic fractions suspected of containing TCQ.

The bulked fractions after evaporation to dryness were each oxidized for 1 hr. by boiling with alkaline permanganate, and after removing the excess oxidizing agent with sulphur dioxide were extracted with benzene. Each was again separated chromatographically on an alumina column and again the eluted fractions from the column were examined for the presence of TCQ. It was not found in the unlabelled column. The TCQ fractions were again bulked and re-oxidized, and separated chromatographically.

In none of the four samples examined was the presence of TCQ detected by these methods.

Confirmation of the Gibbs Theory of Elasticity of Soap Films

As long ago as 1878 Gibbs gave an explanation for the fact that liquid soap films behave as elastic membranes, whereas pure liquids do not; he assumed that as a result of adsorption on the surfaces, the solution becomes depleted in surface-active solute, and therefore the surface tension increases with extension of the lamella. The modulus of elasticity, E, of a lamella is defined by:

$$E = 2A\frac{d\gamma}{dA} = -2\frac{d\gamma}{d\ln L} \qquad (1)$$

where γ is the surface tension of the lamella at an area A and thickness L.

Until recently, it was not possible to decide how far this theory is valid for real soap films. On one hand, no measurements of elasticity had been made. On the other, it was known that several other effects contribute to foaming—notably, the dynamic (Marangoni) elasticity, the damping effect of viscous and plastic adsorption layers and the long-range forces between the two parallel adsorption layers, which become important with very thin films ($< 0 \cdot 1\mu$) [1].

Recently, the first experimental determinations of the modulus of elasticity of films have been reported by Mysels, Cox and Skewis[2]. They devised an ingenious method of measuring the increased tension in a soap film while it was stretched to a measured extent, as determined by displacement of the interference bands. As the time-scale of the experiment was several seconds, there should have been negligible contribution from the Marangoni effect because equilibrium between the surfaces and the substrate would be reached within 0·01–0·1 sec. for these films, which were presumably 1–10μ thick. For 0·01 M solutions of sodium dodecyl sulphate, Mysels *et al.* recorded approximate values of the modulus of elasticity in the range 8–20 (mean 15 ± 4) dynes cm.$^{-1}$. The purpose of the present communication is to show, by calculating values of E from surface-tension data, that these results confirm the validity of the Gibbs theory.

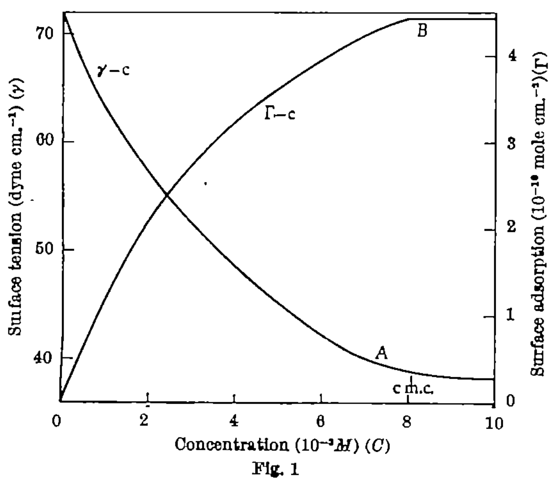

Fig. 1

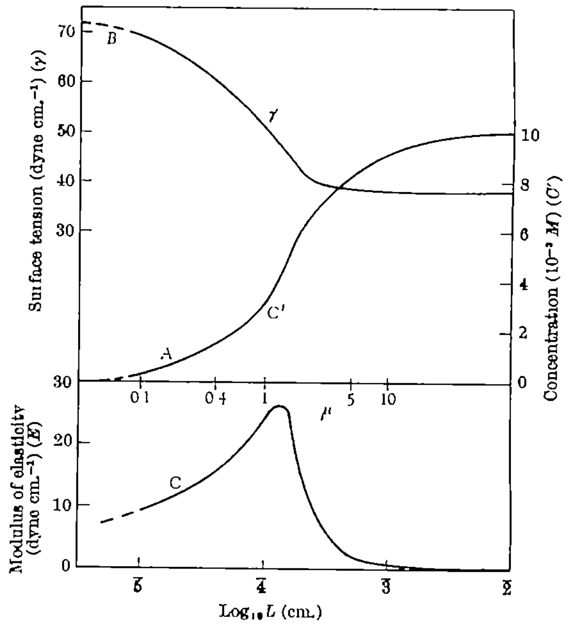

Fig 2

Fig. 1 (curve A) shows the results reported by Clayfield and Matthews[3] for the surface tension of solutions of pure sodium dodecyl sulphate. Curve B gives the corresponding adsorption values, Γ, calculated from curve A by means of the Gibbs adsorption equation, namely:

$$\Gamma = \frac{-1}{2RT}\cdot\frac{d\gamma}{d\ln(Cf_{\pm})} \qquad (2)$$

in which C is the concentration in moles l.$^{-1}$ and $f_{\pm}$ the activity coefficient of solute. (In absence of activity coefficients between the critical micelle concentration (c.m.c.) (0·008 M) and 0·01 M, Γ was assumed constant over this range, any error being negligible.)

If a solution of original concentration C_0 is extended into a lamella of thickness L cm., the depleted bulk concentration C' in equilibrium with the two adsorption layers containing Γ moles cm.$^{-2}$ is given by:

$$C' = (C_0 - 2 \times 10^3\,\Gamma/L) \qquad (3)$$

Curve A in Fig. 2 shows C' as a function of L for a solution starting at $C_0 = 0 \cdot 01\,M$: the values were obtained by solving equation (3) by successive approximations. From these values the corresponding surface tensions of the depleted solutions were read off from Fig. 1A and are plotted in Fig. 2B. Finally, the modulus of elasticity at different film thicknesses was obtained by graphical differentiation of 2B and use of equation (1). The final results are given in Fig. 2C.

It is seen that the Gibbs theory predicts elasticities to develop in this solution at lamella thicknesses in the range 5–0·1μ, with a maximum modulus of about 26 dynes cm.$^{-1}$ at a thickness of 1–2μ. The experimental value of 15 ± 4 obtained by Mysels, Cox and Skewis for films in the range 1–10μ is therefore in satisfactory agreement with the Gibbs theory.

This concord between theory and experiment confirms that the elasticity of thick soap films under quasi-static conditions is governed by the Gibbs effect. It does not mean, however, that the other effects mentioned here are unimportant in foams under other conditions; the evidence for long-range forces in very thin films, for example, is compelling

Photochromism of o-Nitrotoluenes

THE crystals of 2-(2′,4′-dinitrobenzyl)-pyridine (I), which are colourless when kept in the dark, turn blue when exposed to light[1]. Hardwick, Mosher and Passailaigue[1] by using a cryoscopic technique have demonstrated that the change in colour is not confined to the crystals but occurs in dilute solutions as well. A similar change in colour has also been observed with 4-(2′,4′-dinitrobenzyl)-pyridine (II)[2].

Now, by using the flash photolysis technique, I have established the fact that *o*-nitrotoluene and a variety of compounds, all derivatives of *o*-nitrotoluene, are photochromic. In this work, a light pulse of high intensity was obtained by the discharge of 1,800 joules (9 μF., 20 kV.) through four straight quartz tubes (Lindqvist, L., Institute of Physical Chemistry, University of Uppsala) giving a flash duration of 5 μsec. (1/*e* time). Light emitted from the lamps of wave-lengths shorter than 250 mμ was absorbed in a filter surrounding the test solution. The transmission of 20 cm. of the solutions was recorded photoelectrically. All investigations were performed at room temperature (24° ± 1° C.) with the concentration of the compound being about 10^{-4} *M*. No detectable stray light from the exciting flash entered the recording system and the absorption spectra of the coloured solutions were determined at maximum optical density during the flash. The kinetics of the fading reaction were evaluated from the change with time of the light transmission of the coloured solution after the flash.

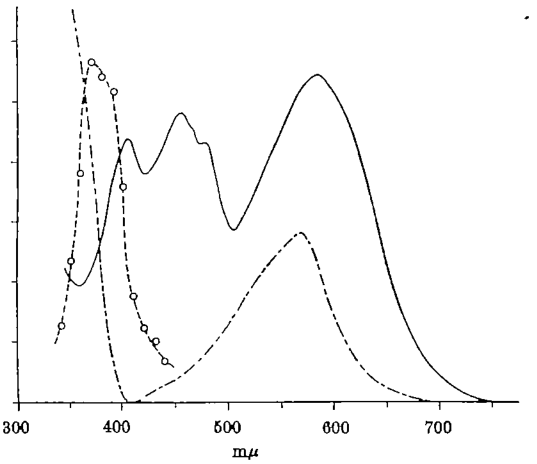

Fig. 1. Absorption spectra of ethanol solutions of *o*-nitrotoluene (– – –), 2-(2′,4′-dinitrobenzyl)-pyridine (–·–·–), and 2-(2′-nitro, 4′-cyanobenzyl)-pyridine (——) after exposure to ultra-violet light. The ordinate is proportional to optical density with different proportionality constants for the different solutions

Compounds examined were *o*-nitrotoluene (III), 2,4-dinitrotoluene (IV), 2-(2′-nitro,4′-aminobenzyl)-pyridine (V) and 2-(2′-nitro,4′-cyanobenzyl)-pyridine (VI) as well as I. It was shown that all these compounds have the property of becoming coloured on exposure to light and then becoming colourless in the dark.

The colourless compounds do not appreciably absorb light of wave-lengths longer than 330 mμ.

The absorption spectra of three of the coloured solutions are presented in Fig. 1. The irradiated solutions of I and VI maintained their colour long enough at – 70° C. to measure the spectra by means of a cryoscopic technique using a Cary 14 spectrophotometer[3]. The spectrum of the irradiated solution of III was obtained at room temperature by means of flash photolysis using a small Bausch and Lomb grating monochromator.

In absolute ethanol the fading reaction in all cases followed the kinetics of a first-order reaction. Rate constants are given in Table 1.

Table 1. RATE CONSTANTS FOR THE FIRST-ORDER FADING REACTIONS IN ABSOLUTE ETHANOL AT ROOM TEMPERATURE

Compound	Rate constant (sec.$^{-1}$)
o-Nitrotoluene	$1{\cdot}3 \times 10^{2}$
2-(2′,4′-Dinitrobenzyl)-pyridine	$1{\cdot}2 \times 10^{-1}$
2-(2′-Nitro,4′-cyanobenzyl)-pyridine	$3\ 7 \times 10^{-1}$

The cycle of becoming coloured and then reverting to the colourless state could be repeated several times without noticeable change in the behaviour of the solution. After 5–10 cycles, however, a change in the rates of the fading reaction was observed; in the cases of I and VI the rates are increased, but in the case of *o*-nitrotoluene the rate is decreased. This behaviour appears to be due to irreversible side reactions which render the solutions acidic since the same phenomena were observed when acid is added to the solution.

A detailed study has been made[4] of the fading reaction of I in water solutions under different conditions of *p*H and the rate of the fading reaction has been found to be increased by a factor of 10^5 when going from *p*H 12 to 2.

A probable mechanism for the change in colour is as follows:

CRYSTALLOGRAPHY

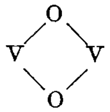
Structure of Vanadium Dioxide

GOLDSCHMIDT[1] came to the conclusion that vanadium dioxide had a rutile structure in which, in its idealized form, each vanadium would be surrounded by a regular octahedral arrangement of oxygen atoms. In fact, in actual rutile structures, the regular octahedral arrangement must always be lost[2] (as is in fact observed), though the unit cell will remain tetragonal, because four of the metal oxygen (or halogen) distances will remain equal. The other two could be different without any loss of symmetry, but it is found that usually they have virtually the same length as the other four (for example, in titanium dioxide four of 1·94 Å. and two of 1·99 Å. and in magnesium fluoride four of 2·00 Å. and two of 1·98 Å.)[3]. The arrangement of the six cations around a metal atom in a tetragonal rutile structure may therefore be visualized as "one at the north pole, one at the south, and four on the equator as a rectangle".

The structure of vanadium dioxide is sufficiently like this for Goldschmidt to have believed that it had a true rutile structure. However, it has been found more recently that the structure is distorted and is, in fact, monoclinic[4]. A detailed examination shows that the oxygen atoms lie very close to what may be described as the 'rutile positions' but that the vanadium atoms are somewhat displaced, the six VO distances being 2·03, 2·01, 2·05, 1·87, 1·86, 1·76 Å. Considerable stress has been placed on the fact that while in a rutile structure the metal atoms lie, equally spaced, on straight lines, the vanadium atoms in vanadium dioxide are spaced alternately 2·65 Å. and 3·12 Å. apart (instead of at regular intervals of about 2·87 Å.; the vanadium atoms are no longer quite on one straight line). As a result it has been proposed that there is metal–metal bonding[5], the vanadium atoms being bonded in pairs.

It has been claimed that evidence for this type of bonding is provided by the correlation of: (*a*) the axial ratios for rutile type phases; (*b*) the metal–metal bond-lengths, with the number of valence electrons supposedly available for each metal–metal bond. It is of course very possible that the degree of distortion may be dependent on the number of valence electrons present on each metal centre—but this may or may not be related directly with metal–metal bonding. It seems to us that there is no evidence that it is so related and in fact that metal–metal bonding does not appear likely to occur in vanadium dioxide or to provide a probable reason for the particular structural distortion that occurs.

The two close vanadium atoms are in a situation which can be represented by:



the four atoms being coplanar. Moreover these two oxygen atoms shown are particularly close to one another. Consequently, the space between the two vanadium nuclei is very much occupied by the electron clouds of the two oxygen atoms, and it is difficult to suppose that there is direct bonding between them in any ordinary sense. Moreover, if metal–metal bonding were the cause of the distortion it would be expected that the two vanadium atoms would be displaced directly towards one another. This is quite definitely not so. The vanadium atoms are displaced partly towards one another, or alternatively towards the oxygens lying between them, but even more towards one of the other oxygen atoms. It is as if there is a displacement of the vanadium atoms from their rutile positions so that a V_2O_4 molecule is beginning to be formed, with the structure shown in Fig. 1. The four oxygen atoms are approximately in a single plane, being close packed in that plane, the two vanadium atoms being placed so that each forms three pyramidally directed bonds, one vanadium being on one side of the oxygen plane and the other vanadium being on the other side. The whole structure is then a particular interlocking pattern of these V_2O_4 units. However, it must be stressed that the structure is really intermediate between this and a true rutile structure since the other three distances (2·01, 2·03, 2·05) are only a little greater than those in the V_2O_4 groupings (1·76, 1·86, 1·87), the incipient V_2O_4 units representing the way in which the true rutile structure is distorted.

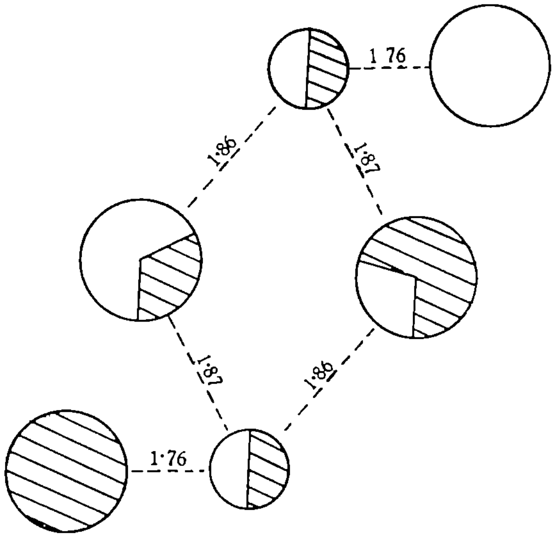


Fig. 1. Diagram showing the arrangement of atoms in the 'V_2O_4 units'. Large circles represent oxygen atoms, small ones vanadium atoms. The degree of shading represents the relative distances of the centres of the circles below the plane of the paper. The numbers give distances between centres (in Å.)

This structure will be analysed in more detail elsewhere and a comparison with the structures of VO, V_2O_3 and V_2O_5 will then be made.

product thus obtained, however, is not suitable for determinations of X-ray structure, because of the poor quality of the powder patterns. Natta *et al.*[1] obtained better X-ray photographs from samples prepared by thermal décomposition of CH_3TiCl_3 (ref. 2). From these photographs they arrived at a crystal structure which is very similar to the structures of the needle-shaped modification of $TiBr_3$, TiI_3 and the zirconium trihalogenides[3].

However, a number of weaker lines calculated from this structure model were not observed, probably owing to the still insufficient quality of the X-ray patterns.

I obtained well-crystallized β-$TiCl_3$ by a very slow reaction according to the above equation using the apparatus shown in Fig. 1. Tubes *A* and *B* were filled with 0·1 molar solutions of $TiCl_4$ and $(C_2H_5)_2AlCl$ in heptane respectively. The apparatus was sealed under vacuum at *P* and *Q* and kept at room temperature for a month. During this period $TiCl_4$ slowly diffused to tube *B*, where butterfly-shaped crystal deposits were formed. These crystals were isolated under nitrogen and used for making X-ray powder photographs.

Fig. 1

Table 1 gives the X-ray data of this compound and these are compared with those published by Natta *et al.* Columns 2, 5, and 7 show that the weaker lines, which were calculated but not observed by Natta *et al.*, were present in our photographs.

In the structure the *x*-parameter of the chlorine atoms features as the unknown. Natta found its value to be 0·315. Although the number of crystallographic data has been extended by this investigation, it is still too small to permit judgment on the reliability of the value mentioned. However, in view of the agreement between the experimental and calculated values of the intensities of the new reflexions found, it seems justified to conclude that the model of this β-modification is correct.

I thank Dr. Hn. de Vries for help with the apparatus.

Crystal and Molecular Structure of *Cyclo*tetradecaheptaene

The crystallographic constants at room temperature of the alternant hydrocarbon $C_{14}H_{14}$, kindly supplied by Prof. F. Sondheimer and Dr. Y. Gaoni of the Organic Chemistry Department of this Institute[1], are: $a = 15{\cdot}05$ Å., $b = 4{\cdot}35$ Å., $c = 8{\cdot}63$ Å., $\beta = 106{\cdot}5°$, space group $P2_1/a$, X-ray density 1·12; $n = 2$, indicated molecular symmetry $\bar{1}$. If the molecular centre of symmetry is not an artefact due

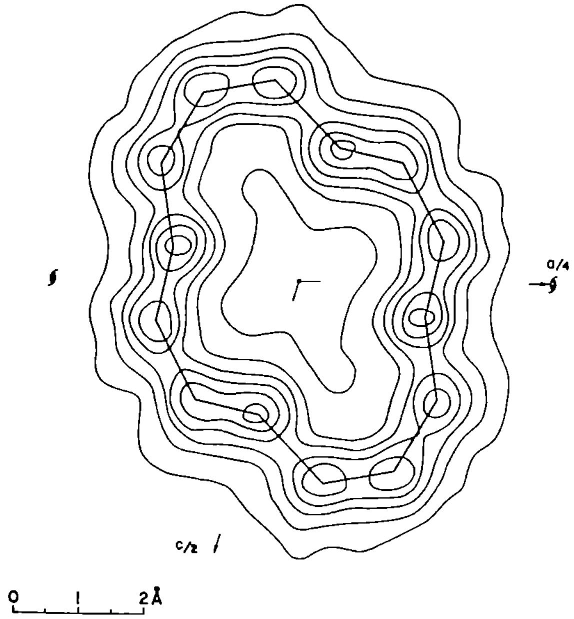

Fig. 1 $C_{14}H_{14}$, $\rho(x,z)$ at room temperature. Contours at arbitrary intervals

to packing disorder, it precludes the presence of alternating single and double bonds around the carbon ring, here as in $C_{18}H_{18}$ (ref. 2).

The intensities of the ($h0l$) reflexions (110 observed) were measured visually from zero-level Weissenberg photographs taken at room temperature, and corrected in the usual manner. The approximate molecular orientation of the molecules centred at (0,0) and ($\frac{1}{2}$,0) was determined by the permutation Fourier technique[3] from nine strong low-order reflexions (two reflexions with arbitrary signs, and seven reflexions permuted sixteen times). Trial co-ordinates derived from the most acceptable projection were refined on 'Weizac' by a least-square procedure, allowing one isotropic thermal parameter per atom, to a conventional R factor of 16 per cent. The final electron density projection is shown in Fig. 1.

The molecule is seen to correspond to a distorted pyrene structure. The projected distance between carbon atoms that in pyrene are bonded to the same interior carbon atom is 2·9 Å., already as long as the closest carbon-carbon approach reported in other overcrowded hydrocarbons[4]. It is probable that a major part of the overcrowding of the carbon atoms has been relieved by in-plane distortion of the carbon ring.

The full structure will be refined from three-dimensional low-temperature data when the possibility of lattice disorder will also be considered.

BIOCHEMISTRY

Action of Chloretone on Reduced Cozymaze Oxidation by Cytochrome c

It has long been known that anæsthetics, including barbiturates and chloretone, suppress brain respiration *in vitro*[1-3], the suppression occurring at concentrations causing narcosis when brain respiration is stimulated by increasing the potassium ion concentration of the medium in which the brain tissue is incubated[4]. Michaelis and Quastel[5] concluded that anæsthetics, as represented by chloretone, suppress in the respiratory chain the activity of a flavoprotein forming a link between reduced cozymase (DPNH) and cytochrome oxidase. It was later shown[6], in accordance with this conclusion, that 'Amytal' suppresses the oxidation, by brain mitochondria, of DPNH and its oxidative phosphorylations. In view of the increasing use of 'Amytal' as a tool in the investigation of respiratory systems, we have carried out experiments to observe whether chloretone is effective in the suppression of DPNH oxidation by cytochrome *c* in a tissue homogenate or mitochondrial system. Chloretone offers a definite advantage over sodium amytal in not being ionized in solution and hence in not interfering with electrolyte equilibria.

Two sources of the DPNH cytochrome *c* reductase system[7] have been used.

(*a*) Rat brain homogenate. The animals were decapitated, the brains excised and homogenized in a Potter-Elvehjem homogenizer, under ice cooling, in 0·25 *M* sucrose with 0·001 *M* sodium versenate added. For each gram of fresh brain 10 ml. of the medium were taken.

(*b*) Dog liver mitochondria. A biopsy sample, weighing 15 gm., was taken under light 'Nembutal' anæsthesia and homogenized in an ice-cooled de Virtis homogenizer for approximately 1 min., in 10 × v/w in 0·25 *M* sucrose containing 0·001 *M* sodium versenate. The mitochondria were isolated in a refrigerated centrifuge at 0° C. The suspension was centrifuged at 700 *g* for 10 min. and the supernatant centrifuged again at 700 *g* for another 10 min. This was repeated once more. The sediment was discarded and the supernatant was centrifuged at 5,000 *g* for 10 min. The precipitate was washed in the centrifuge with the sucrose-versenate solution using a Potter-Elvehjem homogenizer. This is a modification of Hogeboom's method[8].

Table 1. EFFECTS OF CHLORETONE ON OXIDATION OF DPNH

Values give changes of optical density (at 550 mμ) per min. per mgm. protein

Tissue system	Control	With chloretone	
		0·67 m*M*	2·0 m*M*
Dog liver mitochondria	61·6	47·1	—
Rat brain	14·9	11·3	5·9

The assay was carried out with the Beckman *DU* spectrophotometer at 550 mμ. Protein was determined by the method of Folin–Ciocalteau using the Beckman *DU* spectrophotometer at 750 mμ. Chemicals were of analytical grade and were dissolved in triple distilled water. Into each cuvette the components were pipetted in the sequence given: 0·2 *M* *p*H 7·4 phosphate buffer, 1·0 ml.; cytochrome *c* (Sigma) 0·6 m*M*, 0·2 ml.; DPNH (Sigma) 6 m*M*, 0·1 ml.; sodium cyanide 7·5 m*M*, 0·2 ml.; sodium chloride 0·85 per cent to give a total volume of 3·0 ml.; chloretone 10 m*M*, 0·2–0·6 ml.; and enzyme suspension 0·2 ml. Temperature was 25° C. (thermospacer). Readings of optical density were taken either manually at 1-min. intervals or with the

Gilford optical density converter, and recorded with a Texas Servoriter No. 500. Units of activity are the changes in optical density/min./mgm. protein. Typical results are shown in Table 1. These results show that chloretone, like sodium amytal, exerts a considerable inhibition of DPNH cytochrome *c* reductase in a brain homogenate or in a preparation of dog liver mitochondria.

Terminal Amino-Acid Analysis of Vasculokinase-activated Fibrin

IN recent experiments in this laboratory, a substance has been demonstrated in human aortæ which is capable of coagulating fibrinogen independently of thrombin[1]. This factor, vasculokinase, appears to have no esterase, amidase or gelatinase activity. Nevertheless, its capability of catalysing fibrinogen to fibrin suggests that it may be a proteolytic enzyme. In previous experiments by Lorand and Middlebrook[2], it has been shown that the *N*-terminal amino-acids of the fibrin monomer catalysed by thrombin are tyrosine and glycine. It has been suggested that there is a specific peptide site in the fibrinogen molecule which must be split in order for the monomers to polymerize[3-4].

In order to test this hypothesis, various fibrins were formed and coupled with 2,4-dinitrofluorobenzene according to Sanger's technique[5]. Thrombin-catalysed fibrin was made from Parke-Davis thrombin and partially purified fraction I (Armour). A similar product was prepared from Parke-Davis thrombin and a purified fibrinogen prepared by the Blomback's technique[6] (kindly provided by Dr. U. Westphal, Ft. Knox, Kentucky). Similarly, two vasculokinase-catalysed fibrins were prepared by the activation of Armour fibrinogen and Blomback fibrinogen with purified vasculokinase[7].

Various digestion processes of the coupled fibrin were utilized. These included digestion with 6 *N* hydrochloric acid under nitrogen, digestion with perchloric and acetic acids under nitrogen and reflux digestion with 6 *N* hydrochloric acid.

The coupled amino-acids were subjected to paper chromatography on Whatman No. 1 filter paper. 2 chloroethanol, pyridine, toluene and ammonia (6 : 3 : 10 : 6) were used in the organic dimension and phosphate buffer, 1·5 *M*, was used in the polar dimension.

The observation that the *N*-terminal amino-acids of thrombin-catalysed fibrin are tyrosine and glycine was confirmed. The *N*-terminal amino-acid of vasculokinase, however, was found to be phenylalanine. Inasmuch as the *N*-terminal amino-acids of fibrinogen are glutamic acid and tyrosine[8], it must be concluded that vasculokinase splits the fibrinogen molecule at a different site from thrombin. Although the liberated peptide has not as yet been recovered and evaluated for its size, these results suggest that vasculokinase is indeed a proteolytic enzyme. The results also suggest that there is more than one locus in the fibrinogen molecule which may be cleaved and still permit polymerization to fibrin fibrils.

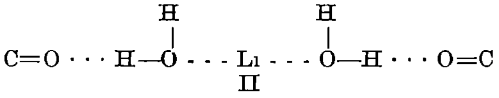
Evidence from Model Peptides relating to the Denaturation of Proteins by Lithium Salts

IN an earlier communication[1] we reported that mixtures of *N*-methylacetamide (NMA) or *N,N*-dimethylacetamide (DMA) with strong aqueous lithium bromide show viscosities much higher than those calculated on the assumption of ideal mixing. This was termed 'relative viscosity', which is different from the usual use of this term. It was proposed that the high viscosity is caused by aggregation arising from carbonyl–lithium (I) and carbonyl–water–lithium (II) associations.

$$\mathrm{C{=}O\ -\ -\ -\ Li\ -\ -\ -\ O{=}C}$$

I



$$\mathrm{C{=}O\cdots H{-}\overset{\overset{\displaystyle H}{|}}{O}\ -\ -\ -\ Li\ -\ -\ -\ \overset{\overset{\displaystyle H}{|}}{O}{-}H\cdots O{=}C}$$

II

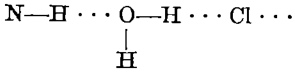
Dots indicate hydrogen bonds, and dashes ion-dipole interactions. These associations were also considered to occur in protein denaturation. We now report evidence for the existence of both types of association, as well as peptide-anion associations.

We had reported[1] that on mixing NMA and 13 *M* lithium bromide (incorrectly reported as 12 *M* before) in the volume ratio 4 : 1 (also molar ratio), respectively, a crystalline precipitate was obtained. The crystals dissolve in their mother liquor at about 53° C. The crystals contain NMA and bromide in the molar ratio of 4 : 1, by analysis. The structure of the crystal has been determined by means of X-ray diffraction by Dr. David Harker and Mr. David Haas, to whom we are grateful for permission to describe some of their results. The detailed structure will be published elsewhere after additional refinement. The main features of the structure that are of interest with regard to protein denaturation are as follows: each lithium is surrounded by four carbonyl oxygens and two water oxygens; each bromide is surrounded by hydrogens of four N—H groups and of two water molecules. Each water molecule forms a bridge between a lithium and a bromide. Bromide to H—N association has recently been proposed by Bufalini and Stern[2] to account for infra-red data obtained from dilute solutions of NMA and tetrabutylammonium bromide in benzene. We have not been able to apply our viscosity method with tetramethylammonium bromide due to immiscibility with the amides at the high concentrations required.

The participation of water in the aggregates was investigated by the use of deuterium oxide (all viscosity data are corrected for density). A mixture of 64 volume per cent DMA and 36 volume per cent 10 *M* lithium chloride in deuterium oxide is 1·13 times as viscous as a similar mixture made with water. For mixtures of NMA and lithium chloride the deuterium oxide system is 1·16 times as viscous as the water system, using NMA in which the N—H previously had been exchanged to N—D. The viscosity of 10 *M* lithium chloride in deuterium oxide is 1·16 times as great as that of 10 *M* lithium chloride in water. The amide–lithium salt system has only 0·36 of the water content of 10 *M* lithium chloride alone. Therefore, in the above mixtures of amide and 10 *M* lithium chloride the viscosity increase due to deuterium is 2·3–2·8 times the increase due to deuterium in 10 *M* lithium chloride without amide. These results show a significant participation by water, for which formulations II–IV are reasonable. Lithium–chloride ion pairs or higher ion aggregates may also participate.

$$\mathrm{C{=}O \cdots Li \cdots \underset{\substack{|\\ H}}{O}{-}H \cdots Cl \cdots H{-}N{-}}$$

III



$$\mathrm{N{-}H \cdots \underset{\substack{|\\ H}}{O}{-}H \cdots Cl \cdots}$$

IV

In comparing DMA–deuterium oxide with DMA–water, the viscosity increment due to deuterium is 11 per cent compared with 13 per cent given above for the complete system, DMA–salt–water. Correcting for the lower water content in 10 *M* lithium chloride (43 *M*) than in pure water (55 *M*), the deuterium increment for DMA–lithium chloride–water is 30 per cent greater than for DMA–water. It thus appears that the potency of water in aggregating amides is augmented by its association with lithium ions, which would be expected to increase the hydrogen bonding ability of water by decreasing the shielding of the proton. Also a group of water molecules around a lithium ion has many possibilities for hydrogen bonding, leading to large aggregates.

There may also be interactions between the halide ion and the peptide dipole. This is of interest especially in connexion with peptides of imino-acids. No crystalline complex of DMA and lithium bromide could be formed under our conditions; but Kumler[3] has prepared the solid hydrochloride of DMA, the structure of which would be of interest. The higher viscosity of DMA-lithium bromide compared with NMA-lithium bromide[1] may be only apparent, the resultant of an increase due to the salt and a decrease due to disruption of the structure of liquid NMA, which is more viscous than DMA.

That both ions are involved in the aggregation is suggested not only by X-ray diffraction, but also by the fact that 7·4 *M* sodium bromide raises the viscosity of NMA half as much as does 8 *M* lithium bromide, but about three times as much as does water. Lithium bromide is somewhat more effective than lithium chloride, the peak relative viscosities for 10 *M* salt with DMA being 14 and 12, respectively. (The value of 8 for the peak viscosity previously reported was obtained with unpurified DMA; ion exchange followed by distillation through a 60-cm. column packed with stainless steel mesh resulted in the new value of 14.) The greater effect of bromide is in accord with the well-known fact that bromides are more effective denaturants than chlorides, although the hydrogen bonding and ion-dipole interactions of chloride are expected to be greater than for bromide. Fluoride may be an anti-denaturant; it raises the melting point of a gelatin gel[4].

The various peptide-ion interactions proposed may be involved in protein denaturation. It is possible that unfolding of a particular protein may occur by another mechanism, for example, disruption of the water structure. The unfolded protein may enter into the associations proposed here. At the low protein concentrations normally examined there would be little aggregation. In concentrated protein solutions the salt and water may cause aggregation as indicated by the following observations. The relative viscosity (in the usual sense as applied to polymers) of 1 per cent gelatin in 7 *M* lithium bromide is about 10 per cent higher than in dilute buffer, while at 35 per cent gelatin concentration the relative viscosity in lithium bromide is six times as great as in water.

Deoxyriboside Control and Synchronization of Mitosis

In seeking simple physiological methods for blocking followed by synchronization of cell division, materials were sought which, applied for prolonged periods, permitted synthesis of ribonucleic acid (RNA) and protein but inhibited cells immediately prior to DNA replication. During this I used excess (2 m*M*) thymidine as a blocking-synchronizing agent.

Monolayers of genetically heterogeneous Chang-appendix cells were grown in medium 199 supplemented with 20 per cent bovine serum in sloping 20 ml. tubes with 3 c.c. medium. The shortest doubling times observed were about 20–23 hr. After 4 days growth (at 36°–37° C.) the tubes contained about 300,000 cells, and were beyond conditions permitting logarithmic growth. Normal cultures showed a mitotic index varying from about 3–7 per cent. At 4 days the medium was decanted and excess thymidine introduced in fresh medium. After 24 hr. (at time 0 hr.) at 36°–37° C. the tubes were washed with two lots of 3 c.c. Hanks's balanced salt solution before addition of fresh growth medium. The monolayers were inspected periodically (× 75 using × 10 objective) in the constant-temperature room. Direct counts of mitoses per field were made in 5–8 fields in a standard region of the tubes. The average number per field was used as the index of mitotic activity.

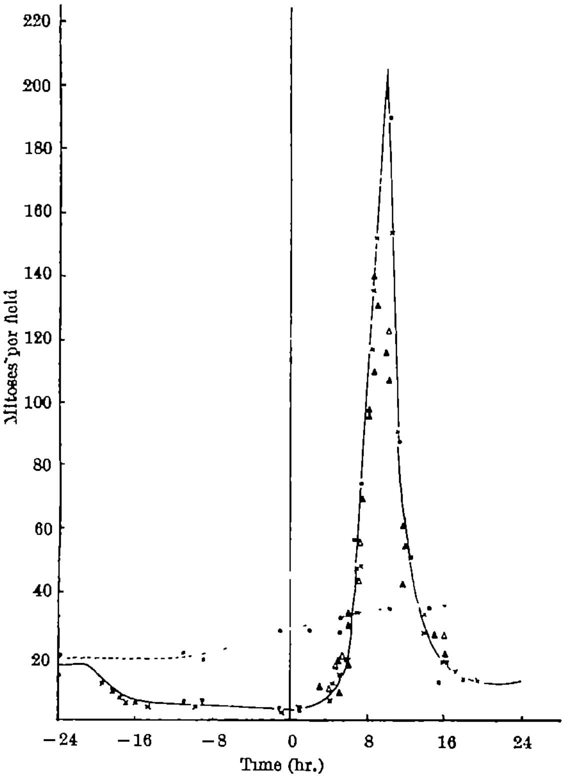

Fig. 1. Mitoses in Chang-appendix monolayer in 199–20 per cent bovine serum. The continuous line shows the inhibition of mitoses during 2 m*M* thymidine blockage (thymidine applied at −24 hr. and washed off at 0 hr.), and the parasynchronous burst of mitoses with maximum at 10 hr. post-wash. The broken line, based on a limited number of counts, indicates the level of mitotic activity in control tubes subject to similar washing at 0 hr.

The curve in Fig. 1 showing the mitotic counts per field over the 24 hr. before and after the removal of thymidine is drawn to the readings of Exps. 1 and 2 performed in successive weeks. The readings made in Exps. 3*a* and 3*b* (begun on the 5th day and with less cells per tube) were added to the graph later. No toxic effects of the 2 m*M* thymidine either during treatment or during the following week were observed. Mitoses appeared normal throughout and were roughly estimated to take about 2 hr. in my material. After removing the block the minimal mitotic index observed in its presence persisted for about 4 hr. The parasynchronized burst began at about 5 hr. and reached a maximum mitotic index at about 10 hr., declining rapidly thereafter. Between 1 hr. and 7 hr. about 7–8 per cent *C*-mitoses accumulated (0·00001 per cent colchicine). Accumulated *C*-mitoses in the 6¼–12¼ hr. period were about 44 per cent, and in the 6¾–12¾ hr. period 40 per cent. 6 per cent *C*-mitoses accumulated in the 17–23 hr. period. Hæmocytometer counts of acetocarmine preparations gave a mitotic index of 11 per cent at 8¼ hr. (Exp. 3*b*) and 19 per cent at 9¾ and 10 hr. (Exp. 2) when counts per field were 90 and more than 180 respectively.

To obtain several successive spikes of near 100 per cent synchronous mitoses clones of selected material in log-phase growth conditions need to be used. The present culture conditions are designed only to facilitate detection of possible physiological blocking-synchronizing agents.

In Exp. 3*b*, 2 m*M* thymidine was re-applied at ½, 1, 1½, 2, 3, 4, and 5 hr. or not at all. All tubes showed a peak of mitoses at about 9¾ hr., the peak itself being lowest (about 60 per field) in those to which the block was re-applied at ½–3 hr., and more than 130 per field in the tube to which the block was not re-applied. The earlier the block was re-applied, however, the slower was the decline of the mitotic count in the post-peak period and the higher the level at 15 hr. The percentage *C*-mitoses accumulated between 6¾ hr. and 12¾ hr. in one tube of each of the eight treatments was 26, 21, 21, 20, 22, 20, 26, and 40 respectively. A few tubes were left in 2 m*M* thymidine for up to 2½ days, with fresh medium containing the same concentration of thymidine being supplied at 40 hr. Mitotic activity began to rise after 30–34 hr. and gradually over the next 24 hr. reached the level (mitoses per field) of the normal controls at 0 hr.

The explanation of the thymidine block to mitosis must be sought largely in the cells' enzymatic mechanisms for the synthesis of deoxycytidine triphosphate from cytidine-5′-phosphate and the inhibition of this synthesis by excess thymidine. Reichard[1] found in cell-free extracts of chick embryo that deoxycytidilate synthesis was strongly inhibited not only by thymidine, but also by the triphosphates of deoxyadenosine and deoxyguanosine. Deoxyadenosine has been reported to inhibit synthesis of DNA in Ehrlich ascites tumour cells[2,3] and in chick embryo mince[4].

In experiments on the Chang-appendix cell system 2 m*M* deoxycytidine did not act as a brake on cell proliferation. A burst of parasynchronous mitoses similar to that obtained by washing was observed in cultures blocked for 24 hr. with 2 m*M* thymidine after simply adding 2 m*M* deoxycytidine to the tubes. The close agreement of the two curves suggests that excess thymidine acts simply, preventing synthesis of DNA by inhibiting the formation of deoxycytidine. In further experiments 2·5 m*M* deoxyadenosine and 1·5 m*M* deoxyguanosine (24 hr. application) each blocked mitosis and their inhibition was released by washing, resulting in delayed parasynchronized bursts of mitoses. Thymidine (2 m*M*, 24 hr. application) appeared not to be toxic to the cells to any significant extent, and has so far proved a more suitable blocking synchronizing agent than the other two deoxyribosides. Since prolonged exposure to thymidine did not produce giant cells it would appear that synthesis of RNA and protein ceased at the point normally appropriate to replication of DNA. It may be supposed that mobilization of spindle protein and spiralization of the chromosomes, etc., awaited replication of DNA and the release of some activator from the doubling chromosomes. The thymidine-blocked system may be useful in attempts to obtain controlled synchronous meiosis. The relevance of the results to the further study of the mitotic cycle and its changing properties is obvious. The use of excess thymidine, and the other deoxyribosides as a possible means of distinguishing DNA from RNA viruses, and for their possible therapeutic effect in cell-virus systems, may be noted.

This work was supported by a grant from the Anti-Cancer Council of Victoria.

Identification of the Main Ethylenediamine Condensate of Noradrenaline with that of Catechol

My attention has been directed to a recent communication[1] by T. Nagatsu and K. Yagi dealing with the identification of the main ethylenediamine condensate of noradrenaline with that of catechol. The authors report some experiments, quote an infra-red spectrum and two microphotographs of crystals. Also, the sentence occurs: "However, the precise identification of these compounds in the pure form has not yet been reported".

In fact, not only "the precise identification of these compounds", but also a rigorous proof of the chemical structure and an independent synthesis of these compounds was reported in a detailed paper by J. Harley-Mason and A. H. Laird more than two years ago[2], and all the experiments reported by the Japanese authors are contained in this paper.

[2] *Tetrahedron*, 7, 70 (1959).

Though we missed the report by J. Harley-Mason and A. H. Laird (*Tetrahedron*, 7, 70; 1959), we realize that the results reported in our communication are identical with a part of the results reported by them. Therefore, as a result, our communication serves to confirm their results.

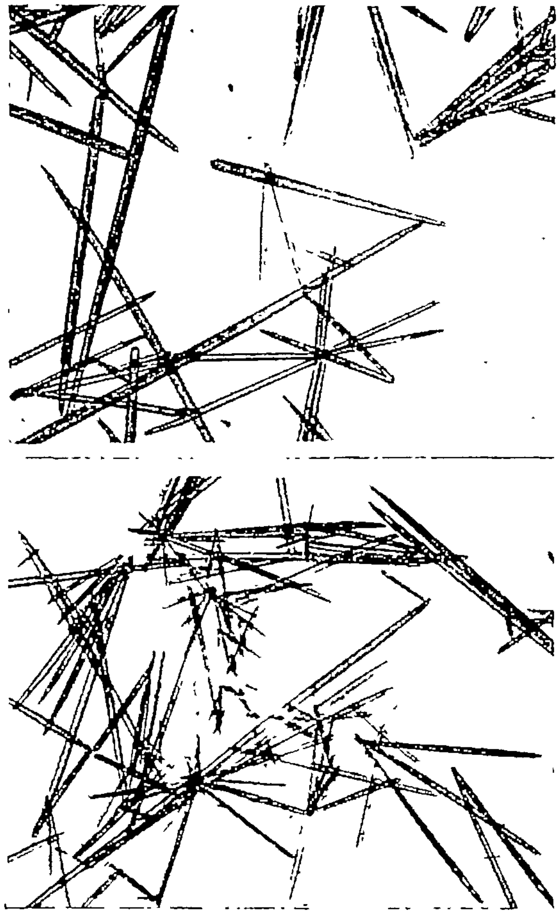

Fig. 1. Picrate crystal of a main ethylenediamine condensate of catechol (above); noradrenaline (below) (× 1,000)

We may add another fact confirming the identification of both the main condensates. We isolated both substances as picrates. Both picrates formed similar, needle-shaped, orange red crystals (Fig. 1)

The infra-red spectra of both picrates were identical. The result of elementary analysis of picrate crystals of the main noradrenaline–ethylenediamine condensate was as follows: calc. for $C_{10}H_{10}N_4 \cdot 2C_6H_3N_3O_7$, C: 41·00, H: 2·500, N: 21·74, O: 34·76; found, C: 40·96, H: 2·695, N : 21·67, O : 34·55 per cent.

This result corresponds with the dipicrate of tetrahydro-tetra-aza-anthracene, confirming the result of Harley-Mason and Laird.

Determination of Free Amino-Acids in Human Ejaculate by Ion Exchange Chromatography

Reports on investigations concerning the content of free amino-acids in human ejaculates are rare. Sakar, Luecke and Duncan[1] estimated the amino-acid composition by microbiological methods. Adam and Korting[2], Jacobsson[3] and Lundquist[4] separated amino-acids from human sperm liquor qualitatively by paper chromatography. Keutel and Gabsch used paper chromatography for qualitative and quantitative determinations of amino-acids from ejaculates[5].

We analysed quantitatively the content of free amino-acids in sperm liquor by ion exchange chromatography[6] using an automatic recording equipment[7]. The method is capable of giving reproducible recoveries of better than 100 ± 3 per cent for quantities ranging from 0·25 to 2 μmoles of amino-acid. One complete analysis required 2 days.

Four to six hours after ejaculation, a 10-fold amount of 1 per cent picric acid according to Hamilton's method[8] was added to the ejaculate. The picric acid precipitate was removed promptly by centrifugation. To remove excess picric acid from the protein-free ejaculate, the solutions were passed through columns of 'Dowex 2' (2 cm. diam.)[9]; a bed 2 cm. in height was used. The colourless effluents were filtered with 'Celite' if cloudy and hydrolysed for 24 hr. with 100 ml. 6 *N* hydrochloric acid under reflux to split peptides and conjugated amino-acids, if present. The hydrolysate was dehydrated three times in a rotary evaporator, treated with 'Celite', when necessary and made up to a volume of 5–10 ml. with a 0·2 *N* sodium citrate buffer, *p*H 2·2 [10]. All solutions were kept frozen prior to chromatography. An amount of the hydrolysate corresponding to 0·5 ml. of the original ejaculate was chromatographed in most instances. The samples were analysed on columns of 'Amberlite *IR*-120' using a self-designed amino-acid analyser[11].

Table 1 shows the average values of 10 patients with normospermia, 5 with azoospermia combined with Leydig cell insufficiency and one patient with aspermia due to deformity of accessory sexual glands. Fig. 1 demonstrates a typical effluent curve of free amino-acids from an ejaculate of a case of normospermia.

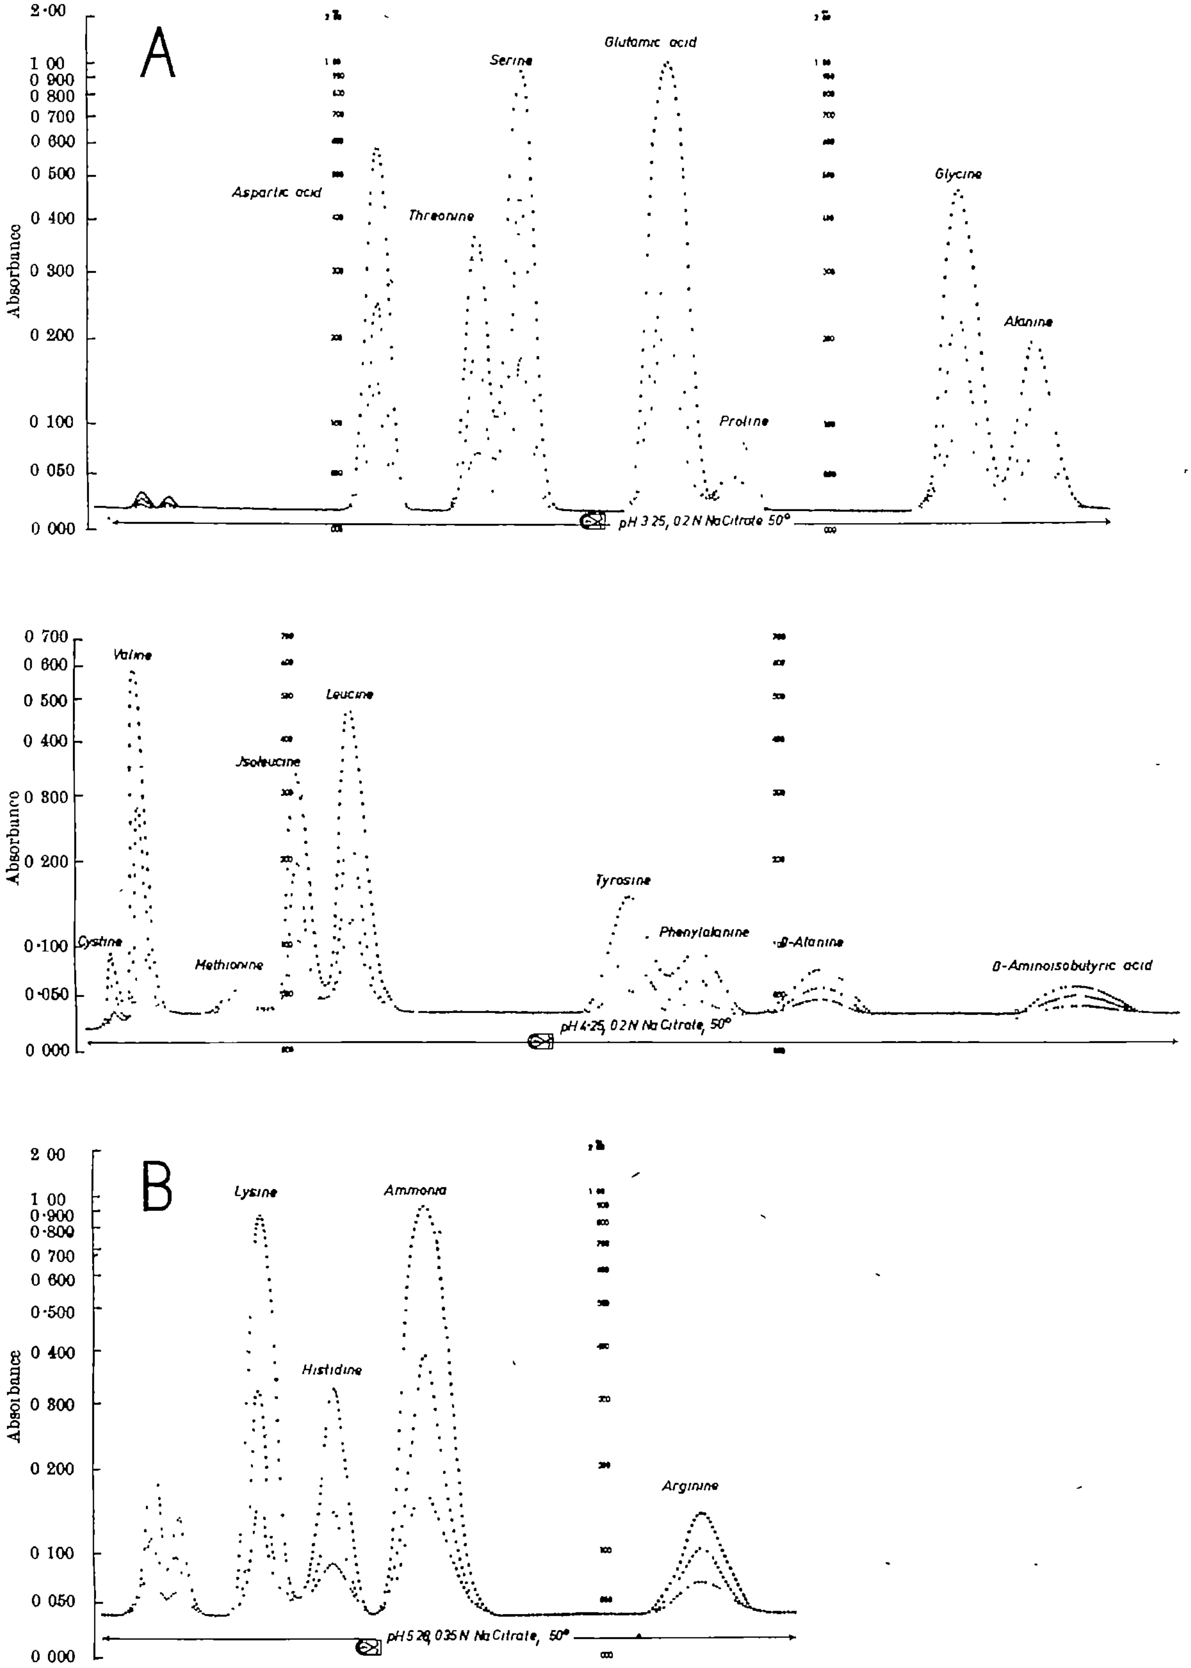

Fig. 1. Typical effluent curve of free amino-acids from an ejaculate of a case of normospermia. *A*, 150-cm. column 'Amberlite *IR*-120' at 50°, *B*, 15-cm. column of 'Amberlite *IR*-120' at 50°

Table 1. Amino-Acids in Human Ejaculate and Blood Plasma Determined by Ion Exchange Chromatography

Neutral amino-acids	Normo-spermia (mgm /ml.)	Azoo-spermia (mgm./ml.)	Aspermia with deformity of accessory sexual glands (mgm./ml.)	Blood plasma (mgm./ml.)
Methionine	0·038	0·007	0·011	0·0008
Cystine	0·034	0·006	0·015	0·010
Glycine	0·589	0·230	0·071	0·018
Alanine	0·291	0·096	0·043	0·036
Proline	0·269	0·139	—	0·016
Tyrosine	0·514	0·232	0·101	0·009
Valine	0·498	0·134	0·100	0·037
Phenylalanine	0·282	0·164	0·112	0·009
Threonine	0·477	0·190	0·115	0·012
Serine	1·116	0·429	0·104	0·010
β-Alanine	0·360	0·158	0·152	—
β-Aminobutyric acid	0·317	0·053	—	—
Isoleucine	0·624	0·191	0·087	0·023
Leucine	0·967	0·332	0·228	0·013
Total	6·376	2·361	1·139	0·1938
Acidic amino-acids				
Aspartic acid	0·998	0·336	0·187	0·007
Glutamic acid	1·797	1·552	0·397	0·094
Total	2·795	1·888	0·584	0·101
Basic amino-acids				
Arginine	0·790	0·295	0·094	0·014
Lysine	1·521	0·580	0·183	0·027
Histidine	1·091	0·398	0·079	0·014
Total	3·402	1·273	0·356	0·055

It is remarkable, however, in those cases having Leydig cell insufficiency and aspermia with normal function of Leydig cells and deformity of accessory sexual glands, the values were essentially lower than in cases of normospermia.

It could be observed that the amino-acid content in the semen was higher than in the blood plasma.

Normal and pathologically changed values of initial fructose did not run parallel with the amino-acid values. One patient with azoospermia due to a stoppage of spermiogenesis and normal function of Leydig cells showed no particular difference from normal values.

It was seen that the content of amino-acids from an individual ejaculate was rather constant when picric acid was added at the time after ejaculation. An increase in the values of amino-acids after ejaculation could be observed in ejaculates of only some of the tested patients.

The content of amino-acids as well as fructose and inositol in human ejaculates probably depends to a high degree on the normal function of the Leydig cells. Owing to the expensive and time-consuming method, this type of amino-acid determination in human ejaculate is not suitable for routine analysis such as the estimation of fructose.

PHYSIOLOGY

Permanent Fibrin Film on the Intima of the Vessels

According to Copley, the intima of blood vessels is lined with a thin fibrin film which protects the surface from becoming wet and facilitates the flow of blood[1]. There are indications that fibrin forms at the sites of physiological defects of the vessels[2]. Fibrin is being continuously formed during fissure in the vessels under the influence of the blood's fibrinolytic activity[1,2]. These views have so far not been checked. The possibility of continuous fibrin formation is denied on the basis of investigations of fibrinogen iodine-131 turn-over. It was found that the half-life of fibrinogen in dogs is not changed when the animals were given heparin or coumadil, the drugs that inhibit the transformation of fibrinogen into fibrin[3]. Our experiments testify against the existence of a permanent fibrin film on the intima of vessels.

The presence of a fibrin film on the intima of the vessels would inhibit the passage of albumins through the vascular wall[4]. Evans blue forms complexes with plasma albumins, and consequently the rate of its excretion from the blood is an indicator of the speed at which the plasma albumin passes through the vascular wall[5]. An investigation was carried out to find the rate of excretion of Evans blue from the blood of 9 normal dogs and 19 animals of which the blood fibrinolytic activity had been stimulated by heparin[6] or nicotinic acid[3]. A 0·2 per cent solution of Evans blue was administered (0·6 ml./kgm.) intravenously in dogs 30 min. following the intravenous administrations of heparin (5 μ/ml. of blood) or nicotinic acid (1 mgm./kgm.) solutions. An increase of the blood's fibrinolytic activity should, presumably, create conditions for the formation of the fibrin film.

The concentration of Evans blue in the plasma was determined by photometry at 610 mm. with 30-, 60-, 90-, 120-, 150- and 180-min. intervals following the injection of the dye into the blood stream. The exponential curves (the axis of the ordinate showing concentration of Evans blue, and that of abscissa indicating time) were used for calculating the time of the semi-excretion of the dye from the organism. The fibrinolytic activity of the blood was determined by the partial lysis time (3 hr.) of a fibrin clot[7] and by the time of lysis of the euglobulin fraction (euglobulin time[8]). The experiments were conducted simultaneously on experimental and control dogs.

As a result of Evans blue injection, the fibrinolytic activity of the blood in heparin experiments was increased on the average by 25 per cent, while coagulation took 300 min. (5–8 min. in normal animals). The semi-excretion time of Evans blue in heparin-fed dogs (205, 8 ± 21 min.) and that in the animals which did not receive the drug (205, 8 ± 26 min.) proved the same.

In those animals which received nicotinic acid the blood coagulation-rate was increased somewhat by administration of Evans blue, and the fibrinolytic activity of the blood showed an abrupt rise (Table 1).

The difference probability (P) was calculated by the Student's t test with respect to the initial data.

Nicotinic acid also failed to change the rate of Evans blue excretion from the blood (Table 2).

Heparin and nicotinic acid were administered in doses which accelerated fibrinolysis. In this process conditions were created for dissolving the fibrin film, had it been on the intima of blood vessels. Moreover,

Table 1. Fibrinolytic Activity and Coagulation-Rate of Blood following the Administration of Nicotinic Acid

	Statistical indices	Prior to administration	Following administration
Coagulation-rate (sec.)	M	336	234
	P	18	0 001
Partial lysis time of fibrin (per cent)	M		41
	P		0 001
Euglobulin time (min.)	M	322	179
	P		0 001

Table 2. Semi-excretion Time (min.) of Evans Blue from the Blood of Animals during the Administration of Nicotinic Acid

Statistical indices	Experimental dogs	Controls
M	160	160
$\delta \pm$	24·5	14 4
$m \pm$	7 6	6 5

in experiments with heparin, the formation of fibrin from fibrinogen anew was quite impossible. In spite of this, the rate of passage of Evans blue, and hence plasma albumin, through the walls of blood vessels, did not change. This last observation in particular casts doubts on the existence of a fibrin film on the vascular intima as well as on the participation of fibrin in normal vascular permeability.

Arterial and Tonometric Pressure Measurements in the Eye

An accurate tonometer has been described for measuring the pressure within the human eye, and within various other body cavities[1,2]. It has an exact theory, can be used in any orientation, and is sufficiently fast and gentle so that it does not require anæsthesia for application to the human cornea. The probe of this unit is pressed against the eye and, in essence, if the cornea is momentarily flattened to slightly beyond a pressure sensitive spot on the tip of the flat end of the probe, then the only force sensed will be the intraocular pressure. However, satisfactory results were not obtained on application to sclera. This has now been demonstrated to depend in part on the adjustment of the degree of flatness of the probe end.

The pressure-sensitive spot in the centre of the probe is a rod the end of which is coplanar with the surrounding plate, and which activates a differential transformer[3]. For reasons of cleanliness, the unit is encased in a thin sterilized cover before use. If the output of the instrument as a function of pressure in a test cavity is plotted (Fig. 1), one sees that the result depends on the initial perfection of the plunger setting. Fig. 1 shows the result of application of the tonometer to a condom at the base of a water column, but similar curves are obtained with excised rabbit eyes and with rabbit eyes *in vivo*. If the plunger initially projects beyond the base plate then the cornea and/or the rubber covering will effectively increase the area of the plunger until increasing pressure moulds them down into full contact with the projection. Similarly, the rubber covering can sustain some of the force if the plunger is initially recessed, until it has been fully moulded down into the recess. This leads to curves that are concave downward and upward respectively, as shown. Corneal readings are usually lower than scleral in the former case, and vice versa. This indicates the sclera to be the less elastic. All the curves eventually become parallel when just the actual area of the plunger is effective. It can be seen that, for a 1·5-mm. diameter plunger, a 5μ initial projection is ideal. A tonometer when adjusted this way indicates its plunger to be projecting 5μ when pressed into contact with a flat glass plate. This may apply only to a given method of construction in which irregularity can extend the plunger surface above and below the surrounding plate, thus leaving the average almost coplanar.

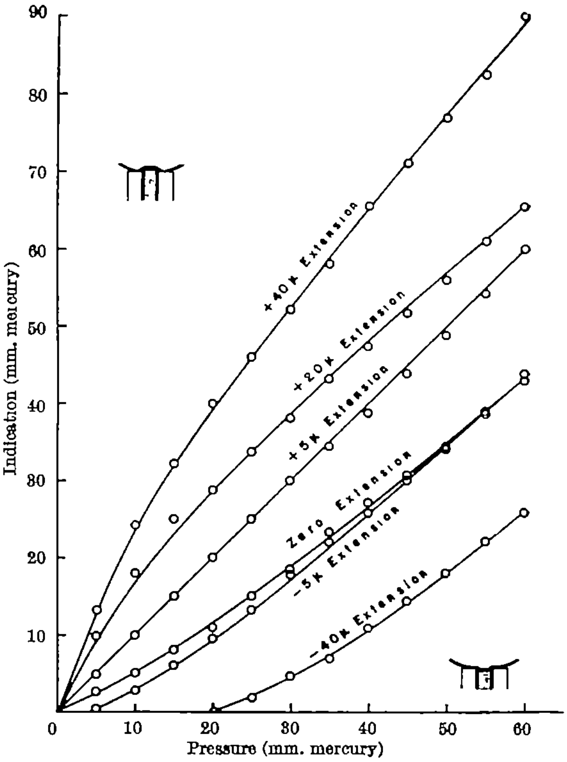

Fig. 1. Response of Mackay–Marg tonometer with initial plunger extension as parameter. Curves concave upward result if the plunger is initially recessed, as shown by the sketch in the lower right corner, and the curve is concave downward if the plunger is initially extended as shown by the sketch in the upper left corner

A unit tested by the water column measurement to be linear through the origin is often found to give the same reading when applied to the cornea or to the sclera in man and rabbits. However, in a significant number of human subjects scleral and corneal readings sometimes do not agree. Tests were made on a dozen subjects using two tonometers (a type manufactured by Biotronics, Financial Center Building, Oakland, California) simultaneously on a single eye, one tonometer being applied to the temporal sclera and the other to the nasal sclera, or one to the cornea and one to the sclera. These readings were often identical, but not always so. This is probably due to the irregular and somewhat compressible and viscoelastic structure of the sclera. We have noticed occasional unreliable readings in similar larger instruments applied to the abdomen due to inhomogeneities (fat lumps) in the wall, presumably for similar reasons. A larger plunger might help here.

Scleral application was desired so that it would be possible to look into the eye while pressing. Since the end of the probe need be only about 5 mm. in diameter. it can instead be applied to the side of the cornea near the limbus and still leave room to observe the eye through an ophthalmoscope. Raising the pressure within the eye to diastolic by pressing will cause the appearance of appreciable pulsations in the blood vessels, and further increase in pressure to systolic will cause the disappearance of pulse due to collapsing of these vessels. This tonometer accurately records the pressure within the eye during such a procedure. It is observed that different regions may start and stop pulsating at somewhat different pressures. A discussion of these pressures has appeared elsewhere, and the interference with the state of normality that measurement produces[3]. A clinical criterion of insufficiency on one side is often taken to be a 25 per cent difference in systolic pressure between the two eyes. The use of a less-exact tonometer and spring-produced pressure is sometimes termed ophthalmodynamometry. A survey of values will be reported separately, but it can be stated here that, of the first half-dozen subjects tested, the diastolic and systolic pressures fell very roughly in the ranges of 50 and 100 mm. of mercury. In all such observations it is found that pressure does not distort the cornea sufficiently to make ophthalmoscopic observation impossible past the de-centred tonometer. Alternatively, one can record the pressure at which the subject's vision disappears. One can also apply the tonometer centered on the cornea with steadily increasing pressure, and in the record the points of maximum oscillation and cessation of oscillation can be taken as the diastolic and systolic pressures, respectively. However, it is not clear to which vessels these readings apply. A suction method[4] can be used to force contact between the present tonometer and the eye to reduce the effect of extraocular vessels, if visual inspection is not being used.

The pressures in the blood vessels are usually considerably larger than the intraocular pressures observed in tonometry. Because of the eventual parallelism of the curves in Fig. 1, pressure indication errors due to lack of coplanarity tend to be constant in the absolute rather than the percentage sense, and thus adjustment is less critical than for tonometry. It has been found that with the Mackay–Marg tonometer when anæsthetics are not used a somewhat greater variability in pressure occurs than if anæsthetics are used. The operator must select a relaxed instant so that the pressure, which will be accurately measured, is not artificially raised by squinting, etc. The presence of corneal bending forces puts a dip in the recorded pressure vs. time curve that is an excellent indicator of the proper degree of corneal flattening, and hence shows where on the graph the reading should be made. With the best possible centering of the probe on a rabbit eye, the pressure corresponding to this trough will be raised by less than 0·5 mm. mercury due to the observation process. Accidental de-centering of the probe by 1·5 mm. will almost cause the loss of the characteristic tonogram form, and the actual pressure in that case will be raised by 4–5 mm. mercury. (All pressures in these experiments were measured with a low compliance capacitance manometer coupled to the eye through a hollow needle.) Holding the probe at an improper angle as it approaches the eye exercises a smaller effect. For angles up to 10° away from the normal to the surface of the eye the pressure within the eye will be raised by less than 1 mm. mercury at the trough point where the reading is to be taken. The effect of an error in application is probably less with a human eye, though the clip in a rabbit tonogram is often less pronounced than in man, thus implying their corneas to be the less stiff. All known errors raise the indication so high pressures are not missed.

We thank Mr. J. Gould for help in making some of the observations. This work was supported by Aerospace Medical Laboratory Contract *AF*33(616) 7664.

Assay of Thyrotrophic Hormone in Blood

Although many methods for the assay of thyrotrophic hormone have been described, few have been sensitive enough to detect the amounts of hormone normally circulating in the blood, and all have serious shortcomings from the point of view of statistical validity. The method described by Bottari and Donovan[1] involving the measurement of release of iodine-131 from incubated thyroid fragments, while satisfactory from the point of view of sensitivity, suffers from a design which does not lend itself easily to statistical validation. Furthermore, some variation was experienced in the sensitivity of the assay animals, linearity within the stated range of sensitivity was not always obtained, and consequently some erratic results were occasionally encountered.

In the light of further experience, the following modifications have been found to increase the accuracy and the reliability of the assay:

(1) The use of in-bred guinea pigs from a source known to be suitable for assay.

(2) Pre-treatment of the assay animals with either 0·1 per cent propylthiouracil/day for about three weeks, or with tapazole 10 mgm./day for 7–10 days.

(3) The adoption of a standard two-point assay design for each assay with analysis of variance and factorial analysis as described by Bliss[2].

(4) Incubation of the tissue fragments with iodine-131 for 8–10 hr., as against 16–18 hr.

(5) The use of a smaller log-dose interval, usually 0·699, for the two doses, within the limits of 5–150

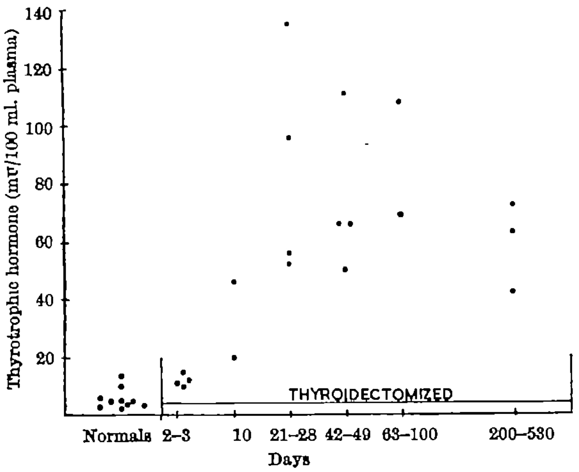

Fig. 1

International milliunits of thyrotrophic hormone per 100 ml.

The mean λ was found to be 0·115 ± 0·002 in a series of consecutive assays. The *F* ratio for the slope was highly significant in all valid assays, *P* varying between < 0·05 and < 0·001 (Table 1). There was no significant deviation from parallelism between International Standard thyrotrophin on one hand, and the thyrotrophic hormone content of human plasma, that of normal rat plasma, and that obtained from the thyroidectomized rabbit. In a series of 30 consecutive assays undertaken on specimens of blood obtained from normal and thyroidectomized rabbits, all tested blindly, only two assays proved to be statistically invalid, and hence had to be repeated. The results were quite consistent with what might be expected on a theoretical basis, namely, that the thyrotrophic hormone content of the blood of the rabbit rises gradually after thyroidectomy (Fig. 1).

It is suggested that this new method (Bottari, Donovan and El Kabir, to be published) is suitable for the assay of thyrotrophic hormone in blood.

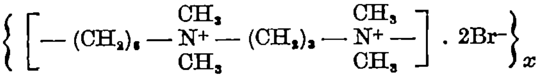
PHARMACOLOGY

Anti-Heparin Agents as Inhibitors of Plasma Kinin Formation

Plasma kinin formation[1] can be induced by treating plasma in a variety of ways, excluding the addition of proteolytic enzymes. In our present work the procedures which we have applied to 'pre-active' human plasma or serum include exposure to a large glass surface[2], addition of ε-amino-caproic acid or disodium edetate[3], dilution[4], re-suspension of the 33 per cent saturated ammonium sulphate precipitate, or addition of the purified kinin-forming material isolated from human plasma (Armstrong, D., and Mills, G. L., unpublished work).

Having observed that heparin[1] and dextran sulphate (Armstrong, D., and Stewart, J. W., unpublished work) accelerate plasma kinin formation, we decided to determine the actions of heparin antagonist drugs on kinin production. We found that both protamine sulphate, and also the non-protein polymer hexadimethrine bromide[5–7] ('Polybrene', Abbott Laboratories, Illinois):



$$\left\{\left[-(CH_2)_6-\overset{CH_3}{\underset{CH_3}{N^+}}-(CH_2)_3-\overset{CH_3}{\underset{CH_3}{N^+}}-\right].\,2Br^-\right\}_x$$

mol. wt. average 6,000 effectively antagonized kinin formation induced by all the aforementioned methods. Toluidine blue, on the other hand, was relatively inactive. Protamine sulphate and hexadimethrine bromide antagonized not only the accelerating action of heparin on kinin formation but also acted as potent inhibitors in the absence of heparin, that is, when production was being induced in citrated plasma, or in serum. They did not interfere with the uterine response to formed plasma kinin, and did not increase the activity of kininase in plasma. Since we have found no evidence of action on substrate, kininogen (in pre-active plasma or serum), their action is apparently on the kinin-forming enzyme itself.

Effective concentrations of protamine sulphate and hexadimethrine bromide are in the range 10^{-6}–10^{-8} gm./ml., the latter being about 50 times the more active of the two compounds. Antagonism of plasma kinin formation induced by glass is an exception, in that higher concentrations of antagonist are required, for example, 10^{-4}–10^{-3} gm./ml., due to the fact that concentration of antagonist in solution is reduced by adsorption on to the glass.

We suggest that the actions of these positively charged macromolecular inhibitors, protamine sulphate and hexadimethrine bromide, resemble those of the naturally occurring inhibitor of kinin formation present in normal human plasma and that the actions of the negatively charged heparin and dextran sulphate molecules resemble those of glass in sequestering off this natural inhibitor from the kinin-forming system.

These agents should assist *in vivo* studies to determine the physiological role of the plasma kinin-forming system.

Changes in the Blood of the Rat induced by the Monocarboxylic Acid of Cyanocobalamin obtained by Fermentation (anti-Vitamin B_{12})

Monocarboxylic acid derivatives of vitamin B_{12} obtained by mild acid hydrolysis are competitive B_{12} antagonists in *Escherichia coli*. The three isomeric monocarboxylic acids so obtained differ from one another in both their microbiological and hæmatological activities[1-3].

By fermenting a strain of *Propionibacterium shermanii* under suitable working conditions, one of us[3] has succeeded in preparing the microbiologically most active monocarboxylic acid isomer in homogeneous form and relatively large amounts.

The following results have now been obtained in hæmatological tests carried out on animals with this homogeneous monocarboxylic acid.

In normal female Wistar rats weighing 120–150 gm. three consecutive 0·1 mgm./kgm. daily doses injected intraperitoneally induced a 50–70 per cent transient reduction in the number of granulocytes. Granulocytopænia reached its peak 4–8 days following injection. The granulocyte count gradually regained normal level by the 12th–14th day. There was no significant change in the number of lymphocytes and red blood cells (Fig. 1).

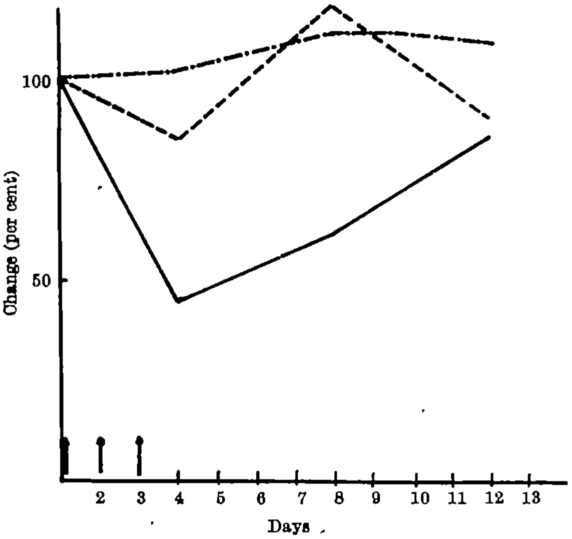

Fig. 1. Effect of monocarboxylic acid derivative of vitamin B_{12} on granulocytic number in normal rats. ——, White blood cell count in animals treated with monocarboxylic acid; —●—, red blood cell count in similar animals; – – –, white blood cell count in controls

Doses increased to 0·5–1 mgm./kgm. failed to produce appreciably more severe granulocytopænia. Administered in doses of 0·1–1·0 mgm./kgm. in combination with our monocarboxylic acid, vitamin B_{12} did not prevent deterioration in the granulocytic count, but methionine did antagonize this effect of the acid.

After their complete blood pictures had been prepared, anæmia was produced in 36 rats of 170–200 gm. weight by withdrawing 3 ml. of blood through the veins of the tail. The animals were then divided into three groups: the first was given 4 consecutive daily 0·1 mgm./kgm. doses of our homogeneous monocarboxylic acid; the second was treated with as much vitamin B_{12}; and the third with sodium chloride only to serve as control. The red and white blood cell counts were estimated daily.

On the evidence of the results presented in Fig. 2, whereas vitamin B_{12} intensified, the monocarboxylic acid slackened, regeneration of red cells.

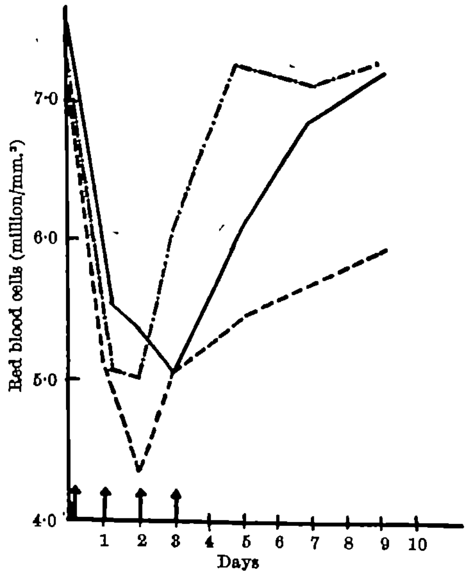

Fig. 2. Effect of monocarboxylic acid derivative of vitamin B_{12} on posthæmorrhagic regeneration of erythrocytes in rats. – – –, Monocarboxylic acid; —●—, vitamin B_{12}; ——, control

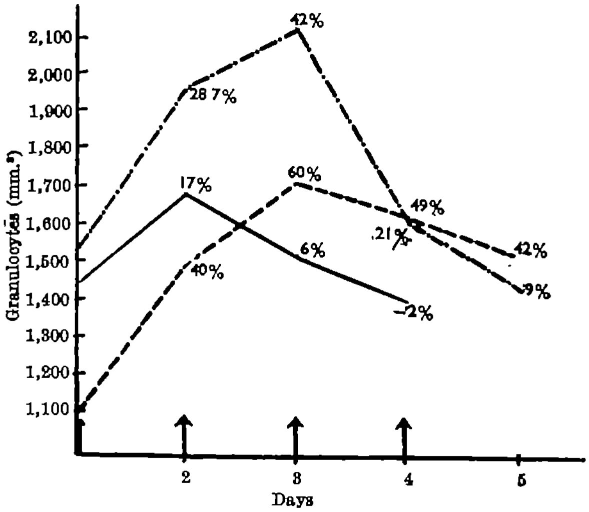

Fig. 3. Effect of monocarboxylic acid derivative of vitamin B_{12} on posthæmorrhagic granulocytosis in rats. ——, Monocarboxylic acid; —●—, vitamin B_{12}; – – –, control

Fig. 3 shows the changes in the white cell count. The monocarboxylic acid markedly inhibited the posthæmorrhagic leucocytosis known to be due principally to a rise in the number of granulocytes. Our qualitative blood examinations likewise confirm the possibility of inhibiting a granulocyte crisis by treatment with monocarboxylic acid.

Summarizing its hæmatological effects on rats, it appears safe to claim that the homogeneous monocarboxylic acid of vitamin B_{12} obtained by fermentation: (1) slackens post-anæmic regenerative red blood cell formation; (2) causes a transient reduction in the number of granulocytes; (3) inhibits post-hæmorrhagic granulocytosis.

PATHOLOGY

5-Nucleotidase Activity in Experimental Cervicovaginal Carcinoma of the Mouse

In the course of a histochemical examination of the distribution of various enzymes in normal and neoplastic cervicovaginal epithelium of the mouse it was found consistently that high 5-nucleotidase activity is typical for malignant squamous cells. This histochemical technique can therefore be considered to have definite diagnostic value.

Squamous cell carcinoma was induced in the cervix and vagina of 34 adult virgin *C3H/N* mice by biweekly visual painting of the portio with 1 per cent benzpyrene in acetone. The animals were killed at intervals so that the various histological steps of epithelial carcinogenesis are represented. A squamous cell carcinoma induced by the same technique was examined in the 79th, 80th and 81st transplantation generations. (We thank Dr. I. Koprowska (Philadelphia), who kindly provided us with the transplantable tumour.) Normal cervicovaginal tissues were provided by 10 intact adult *C3H/N* mice in different phases of the œstrus cycle as well as by 4 ovariectomized animals. The genital tracts, frozen with carbon dioxide, were cut serially at 10μ in a cryostat and treated in order to demonstrate tissue activity of 5-nucleotidase[1]. The 5-nucleotidase activity of the cervicovaginal epithelium is low except in keratinized cells (stratum granulosum and corneum), which display medium staining intensity. Mucified cells (pro-œstrus) are inactive. Cyclic variations in enzyme activity were observed, that is, a gradual increase in the staining intensity of the basal and spinous cells from di-œstrus toward œstrus (maximum activity) followed by a decrease during the katabolic phases of the cycle (metœstrus). The epithelium of castrated mice is devoid of enzyme activity. Subepithelial connective tissue is strongly active for 5-nucleotidase and deeply situated stroma shows somewhat less enzyme activity. Cyclic variations in enzyme activity parallel to those in the overlying epithelium were found in the deep connective tissue only. Polynuclear leucocytes stain intensely whereas macrophages show no activity. Smooth muscle cells (tunica muscularis vaginæ, myometrium and vessel walls) are characterized by high 5-nucleotidase activity, though cyclic variations in intensity did not occur.

The 5-nucleotidase pattern of hyperkeratotic squamous epithelium is identical to that of œstrus epithelium. Dysplastic cells are devoid of enzyme activity except for the luminal cornified cell layers. No enzyme activity was found in intra-epithelial carcinoma. In invasive squamous cell carcinoma (early stromal invasion, micro- and macro-carcinoma) a high activity of 5-nucleotidase was noted in all component cells but the mucified elements (mucoepidermoid carcinoma). Necrotic portions of the tumour corneus material as well as polynuclear leucocytes show more or less enzyme activity. The pattern of reactivity of transplanted squamous cell carcinoma is not different from that of the primary lesion.

The 5-nucleotidase activity in malignant squamous cells (early stroma invasion, micro- and macrocarcinoma) is definitely increased when compared with that of normal and pathological non-invasive (hyperkeratosis, dysplasia and intra-epithelial carcinoma) epithelium. The enzyme pattern of squamous epithelium of the genital tract of the mouse is not unlike that of the human uterine cervix. In the latter epithelium an increase of the 5-nucleotidase activity was noted during pregnancy so that in man, as well as in the mouse, the intensity of the 5-nucleotidase activity seems to be linked with œstrogen. We have established that human intra-epithelial carcinoma of the uterine cervix is inactive for 5-nucleotidase and that squamous cell carcinomas of the same origin showed little to no activity. Only in anaplastic carcinoma of the human cervix could a distinct activity of 5-nucleotidase in the tumour cells be demonstrated. Thus there exists a difference between the 5-nucleotidase pattern of cervical carcinoma of man and mice. In the latter species the histochemical distribution of the enzyme activity can be used for practical purposes, that is, the diagnosis of invasive neoplastic growth, the identification of benign and malignant keratinized cells as well as for the evaluation of the degree of differentiation of benign and neoplastic squamous cells.

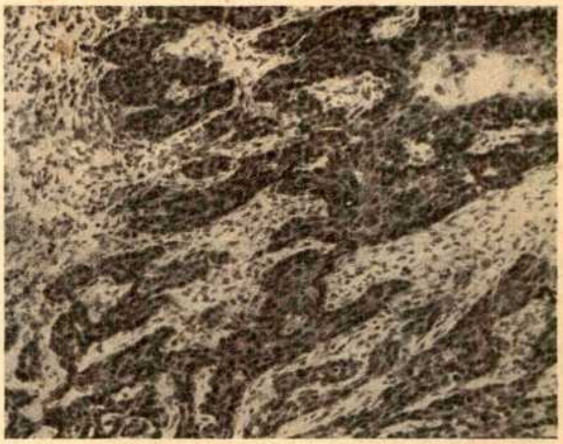

Fig. 1. Transplanted cervix carcinoma (81st generation) (hæmatoxylin–eosin, × c. 105)

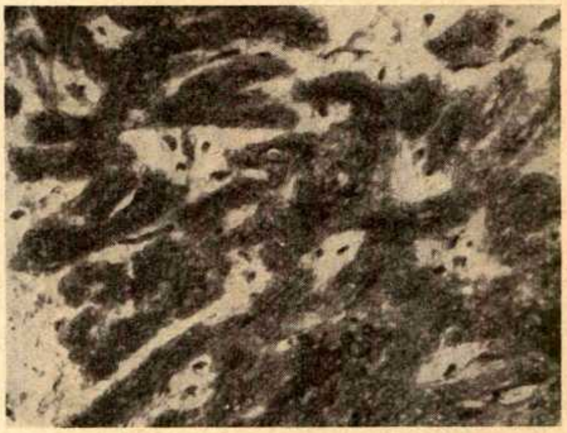

Fig. 2. Activity of 5-nucleotidase in the same tumour. In the negative stroma also activity of 5-nucleotidase can be seen in the capillaries. (× c. 105)

The consistently high 5-nucleotidase activity of malignant squamous cells is quite remarkable, and stands in definite contrast with the activity of most of the enzyme systems studied. Moreover this phenomenon is stable when chemically induced cervicovaginal carcinoma is transplanted for a number (79 +) of generations.

The significance of the high 5-nucleotidase activity in neoplastic cervical cells of the mouse is unexplained.

A high activity of 5-nucleotidase was found in bronchial epithelial cells of mice infected with influenza. In the same cells the influenza virus could be demonstrated by means of a fluorescent antibody technique[2].

The presence of virus-like particles in some of the chemically induced tumours of the mouse cervix has been reported[3].

Therefore it is tempting to relate the increased enzyme activity to the presence of virus-like particles. Another possibility is that the 5-nucleotidase is connected with the syntheses which characterize the process of cornification as squamous cells undergoing keratinization show marked enzyme activity.

Reaction of the Reticular Tissue of Mice with Autoimmune Hæmolytic Anæmia to 2-Aminofluorene

A strain of mice suffering from hæmolytic anæmia of the autoimmune type has been established by one of us (M. B.). This strain designated *NZB/Bl* is now in the 52nd generation of brother–sister mating. Serological signs of the disease, such as agglutinating antibodies[1] and positive Coombs's tests[2], appear in a few animals from the 4th month of life onward, the incidence rising to virtually 100 per cent in animals older than 9 months.

It seemed of interest to test the neoplastic potentialities of the cells of the reticular tissue of *NZB* mice. 2-aminofluorene was chosen as carcinogen because this agent, in contrast to X-rays, carcinogenic hydrocarbons and œstrogens, has no special affinity for cells of the lymphatic system[3]. Apart from *NZB* animals mice of 2 other inbred strains (*NZC* and *NZO*) were used. All 3 strains originated from the same mixed colony and all were known to have a low incidence of spontaneous tumours of the lymphatic system. The mice were painted 3 times weekly with a 4 per cent solution of 2-aminofluorene in acetone for periods of 6–7 months.

As shown in Table 1 only in the *NZB* mice treatment with 2-aminofluorene induced a significant increase in neoplastic lesions of the reticular tissue. In 11 of the 14 affected animals the thymus was involved, but in 3 the process was limited to abdominal organs. One leukæmia, 1 reticulum cell sarcoma and 1 thymoma were transplanted. The grafts grew progressively, causing death of the recipients.

Table 1. INCIDENCE OF LYMPHOMAS* IN MICE TREATED WITH 2-AMINOFLUORINE AND IN CONTROLS

Strain	*NZB*	*NZC*	*NZO*
Total no. of controls	137; 76♂, 61♀	160; 44♂, 116♀	274; 130♂, 144♀
Controls with lymphomas	5; 4♂, 1♀	3; —, 3♀	3; 2♂, 1♀
Total no. of treated mice	72; 35♂, 37♀	73; 45♂, 28♀	76; 36♂, 40♀
Treated mice with lymphomas	14; 7♂, 7♀	1; —, 1♀	2; —, 2♀

* Thymomas, lymphatic leukæmias and reticulum cell sarcomas.

Recent investigations[4] have established that the hæmolytic anæmia of *NZB* mice is an inheritable condition. In offspring of reciprocal crosses of *NZB* with *NZC* or *NZO* mice the occurrence of hæmolytic anæmia indistinguishable from that seen in *NZB* mice has been observed.

The lymphatic elements of *NZB* mice differ from those of the 2 other strains not only by their ability to form auto-antibodies against red blood corpuscles but also by increased susceptibility to 2-aminofluorene, that is, by a higher liability to undergo neoplastic transformation. Whether this is due to a primary instability of these elements or to hyperplastic processes occurring in many lymphatic organs concomitant with the development of the hæmolytic anæmia remains to be investigated.

HISTOCHEMISTRY

Histochemical Localization of β-Glucuronidase in Healing Wounds of the Axolotl

β-Glucuronidase, the enzyme related to cell proliferation and the formation of connective-tissue ground-substance, has been demonstrated in the basal layers of the oral mucous membrane and the epidermis, the blood vessels of the normal corium, in healing wounds of the skin of the back, the tongue and the palate of the rat[1–3], and in healing wounds of the dorsal skin and the tongue of the common iguana[4].

In continuation of this investigation I have examined the activity of this enzyme in healing wounds of the dorsal skin and the tongue of the axolotl *Amblystoma mexicanum*, the animals being killed after 5, 8, 16, 23 and 36 days. After excising the wound with an extensive zone of normal neighbouring tissue and fixation in formalin/chloral hydrate, the enzymatic activity was determined by the method of Fishman and Baker[5] on frozen sections with different incubation times. In the superficial necrotic band of the connective tissue in the 5-day specimens a negative reaction was observed, whereas immediately beneath this negative zone there was an intensely positive zone due to the presence of inflammatory exudate, and particularly leucocytes.

As healing progressed, the fibroblastic proliferation zone reacted moderately but consistently. The histiocytes and giant cells appeared to react more intensely. In the 23-day specimens the epidermis, which had proliferated over the margins of the wound, exhibited a significant increase in enzymatic activity.

In the light of these results I conclude that epithelial proliferation is closely related to β-glucuronidase activity. In connective tissue this enzyme is associated with tissue formation and macrophage function. As these results correspond with those obtained in the rat[1] and in the common iguana[4], more extensive significance must no doubt be attached to the β-glucuronidase.

HISTOLOGY

Preservation of Tissue Sections in Coons's Fluorescent Antibody Technique

In using Coons's fluorescent antibody technique[1,2] for the localization of antigens in tissues, difficulty may be encountered in preserving the sections cut from fresh-frozen material. Although it is customary to dry the sections on to a coverslip in a current of air before staining, dehydration of the sections during storage for several days at the low temperature of the cryostat can cause excessive distortion of the tissue and loss of immunological reactivity of the antigen.

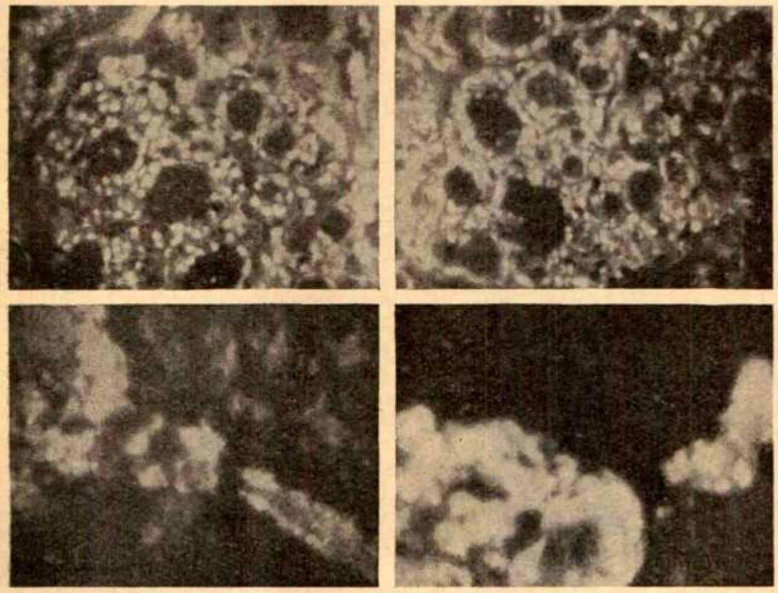

Fig. 1. Top left, The sandwich technique using rabbit anti-human γ-globulin labelled with fluorescein isothiocyanate to demonstrate anti-nuclear factor in the serum of a patient with disseminated lupus erythematosis. The section is of thyroid and was used within 2 hr. of being cut

Top right, Sandwich technique using the same fluorescent labelled anti-human γ-globulin and patient's serum as in top left, but the section of thyroid tissue has been preserved by polyethylene glycol for 2 weeks

Bottom left, Glomerulus of a human kidney treated with a fluorescent labelled anti-β-lipoprotein antiserum to demonstrate the distribution of β-lipoprotein. The kidney section was used within 2 hr. of being cut

Bottom right, glomerulus of a human kidney treated with the same fluorescent anti-β-lipoprotein antiserum. The section was preserved by polyethylene glycol for 4 days prior to use

Any material used to preserve tissue sections for immunological analysis must fulfil certain criteria: it must not interfere with the antigen–antibody reaction by denaturation of protein, it must itself be non-reactive in the antigen–antibody system, and it must be easy to apply.

It was found that polyethylene glycol ('Carbowax', Carbide and Carbon Chemical Co., New York), mol. wt. 285–315 with a freezing range −15° to 8° C., fulfilled the criteria for use as a preserving medium. The polyethylene glycols of higher molecular weight and their methoxy-derivatives have been used for some time as embedding media in pathology[3,4], and the physical properties of suitable mixtures are well recognized[5–7]. The polyethylene glycols of lower molecular weight appeared particularly suitable for our purposes since they are readily soluble in saline and this, together with their small size, renders them easily removed from tissue sections prior to the application of the fluorescent labelled antibody.

These polyethylene glycols of low molecular weight, in distinction to the polyethylene glycols of higher molecular weight, are liquid at room temperature with a freezing point near 0° C. The compounds of higher molecular weight are therefore unsuitable for the technique.

The method used was to take the section mounted on a coverslip and dip it immediately into polyethylene glycol 300 for 5 sec. The coverslip and its section, now coated with polyethylene glycol, were replaced immediately in a cooled rack in the freezing cabinet at − 20° C.; within seconds the polyethylene glycol was frozen solid.

When it was required to use a section treated in this way the coverslip was removed from the cryostat, warmed on the finger and washed in a pool of physiological saline three times for 5 min. each time. The saline should be pooled on the coverslip rather than allowed to flow on the coverslip so that the section does not lift. This procedure was carried out at room temperature. The section could then be treated in the usual manner.

It was found that sections could be preserved without distortion for at least up to four weeks and did not lose their antigen–antibody specificity. The distribution of antigen was apparently unaltered by the procedure. Sections untreated by this method could only be preserved up to 6 hr. before distortion due to dehydration made them unusable (Fig. 1).

Where it is known that the antigens are soluble in saline, the sections may be momentarily dipped in a suitable fixative, for example, ethyl alcohol, methyl alcohol, acetone, prior to coating with polyethylene glycol. In this way the saline used to remove the polyethylene glycol removes a minimal amount of antigen from the tissue.

BIOLOGY

Phases of the Hair-Growth Cycle

MORPHOLOGICAL considerations led Dry[1] to distinguish three stages in the hair-growth cycle; namely, anagen, catagen and telogen. Anagen referred to the period of active growth, including development of the follicle and subsequent synthesis of the hair. The rapid growth in anagen abruptly ceases and the follicle is largely destroyed in a brief phase, termed by Dry as catagen. The follicle remnant and associated hair are in a phase of apparent inactivity known as telogen in Dry's system. This classification of the hair-growth cycle has been extended[2] by subdividing anagen into six phases on the bases of detailed histological observations.

These 'structural' classifications include in one phase (anagen) developmental and functional stages of the hair follicle, and yet distinguish degeneration of the follicle as a discrete phase (catagen). From a physiological point of view, this is clearly unreasonable. To classify the hair-growth cycle in a histologically and physiologically acceptable manner, it is suggested that the term anagen refer only to the phase of follicle development and that the functional phase, between anagen and catagen, be known as metagen. Specifically, metagen would commence with the keratinization of the hair shaft and continue until the synthesis of the hair ceases at catagen.

On structural grounds, telogen has frequently been described as dormant[1-8]. If this were so, it would be permissible to consider the hair-growth cycle as consisting of periods of activity followed by periods of inactivity. Such an interpretation of the growth cycle is, however, misleading, since telogen is not a phase of 'rest'. Metabolically telogen may be regarded as a phase of recovery from the destructive metamorphosis of the hair follicle in catagen. It is the metabolic activity in telogen, however subdued, that results in the initiation of the histological events associated with the phase of anagen. Indeed, the propensity of the follicle to grow hair is a reflexion of metabolic activity during telogen.

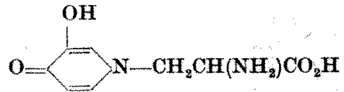
Inhibition of Growth of Hair by Mimosine

Loss of hair in animals following ingestion of seeds and foliage of *Leucaena glauca* was first reported in 1897[1]. Sudden loss of hair in native women has been ascribed to consumption of *Leucaena glauca* seeds[2]. The toxic principle contained in this plant is a water-soluble amino-acid termed leucenol, and is identical with mimosine obtained from *Mimosa pudica*[3]. Mimosine seems to be the preferred name for the compound, both by historical precedent[4] and to avoid confusion with leucinol, an alcoholic derivative of leucine. Mimosine is found primarily in the seeds of *Leucaena glauca*, lesser amounts being present in the foliage and stems[5]. Its chemical structure is:



In this investigation, both purified mimosine and ground seeds of *Leucaena glauca* caused inhibition of growth of hair and loss of hair in mice. Mimosine was extracted from whole ground seeds with boiling water[6]. Its absorption spectrum measured in a Beckman *DU* spectrophotometer was identical with that of a sample obtained from a commercial source (Fluka AG, Chemische Fabrik, Buchs SG). Purity was confirmed by unidimensional paper chromatography (methanol/water/pyridine, 80 : 20 : 4) and column chromatography (150 × 0·9 cm. sulphonated styrene—8 per cent divinyl benzene, Spinco 150*A*, 50° C. at *p*H 4·25).

Mimosine or whole ground seed was mixed with ground commercial mouse pellets and formed into cakes by the addition of agar. Groups of mice were fed with cakes containing 5 per cent and 10 per cent whole ground seed and 0·5 per cent and 1·0 per cent mimosine. Control animals received cakes prepared without seed or mimosine. A large area of the body of each animal was plucked free of hair to induce a new anagen cycle in the hair follicles of these areas.

All animals eating the control diet re-grew thick hair coats in the epilated areas within 8–10 days. The animals fed 5 per cent ground seed and 0·5 per cent mimosine also re-grew hair normally. No hair re-growth was observed in animals receiving 10 per cent ground seed or 1·0 per cent mimosine (Table 1). The 1·0 per cent mimosine diet was continued for 9 weeks with no evidence of new hair in the plucked areas. During the ninth week, loss of hair on the face and head of these mice was noted.

Damage to the roots of hairs in human beings is caused by a variety of cytotoxic therapeutic agents[7]. This damage is due to an inhibition of growing (anagen) hairs. Resting (telogen) hairs are not affected. Gross evidence of loss of hair depends on the degree of damage to the growing hair root. If complete atrophy occurs, the hair is shed from its follicle. Damage to growing hair roots reflects the high metabolic and mitotic activities of these tissues. Compounds toxic for rapidly growing tissues usually cause a proportional degree of damage to hair[7].

The loss of resting hairs is a gradual, continuous physiological process. Normally these hairs are replaced by new growing hairs. If growth of new hair is inhibited there can be no replacement. As a result, the amount of hair remaining is slowly reduced and is often overlooked until it becomes severe. It is this type of loss of hair which occurred on the face and head of mice fed for a long period on 1·0 per cent mimosine.

Table 1. EFFECTS ON GROWTH OF HAIR BY FEEDING *Leucaena glauca* SEEDS OR MIMOSINE IN MICE

Diet	Hair regrowth in plucked area at 8–10 days	Hair loss in facial area at 8–9 weeks
Control	+	0
5 per cent seed	+	0
10 per cent seed	0	+
0·5 per cent mimosine	+	0
1·0 per cent mimosine	0	+

Previous statements that mimosine is incapable of causing loss of hair in some animals[8] or that loss occurs only in young animals[5] failed to take into account the growth-cycle of animal hair. Unless the hairs are in the anagen phase of growth during drug administration, no damage to hair will occur. Many animals exhibit long periods when most hairs are in the telogen phase, and a new growth-cycle must be induced (for example, by plucking) to assess the inhibitory effects of toxic agents. Massive loss of hair in very young rats[5] occurs because most of their hair is in the growing phase.

Mimosine has been shown to act as a tyrosine analogue, capable of inhibition of tyrosine decarboxylase and competitive inhibition of tyrosinase[9]. Thus, the toxic action of mimosine on anagen hairs may be due to inhibition of tyrosine-utilizing enzymes, or perhaps incorporation of mimosine into biologically vital proteins in place of tyrosine.

Swimming-Rate of Bull Sperm

THE velocity of bull sperm has been estimated by a number of different workers in the past few years. Recent reviews have both summarized their results and indicated the diversity of techniques, dilutions, diluents and other conditions which have been used[1,2].

In spite of this diversity, and although many of the factors which have been varied are known to affect the swimming-rate of sperm, results have been sufficiently similar for a value of 100 μ/sec. to be regarded as a good approximation to the 'normal' velocity. This value has been used in order to estimate the time which would be taken by sperm traversing the female tract by their own motility[3].

We have estimated the rate of swimming of bull sperm in a variety of different media, including mucus from the uterine cervix of the cow. We used the simple technique of measuring with a stop-watch the time required for the sperm to swim the length of a calibrated eye-piece micrometer scale. The diluted semen was enclosed in a sealed chamber to prevent evaporation, so that it was possible to record a satisfactory number of rates at 37° C. before the preparation began to deteriorate. Under these conditions, the mean rate of 705 sperm, derived from a number of different bulls, at a dilution of one in 128 in physiological saline, was 131·9 μ/sec. ± 1·25 (*S.E.*). The mean rate for 530 of these sperm the speed of which was estimated within 10 min. of warming to 37° C. was 131·9 ± 1·5 μ/sec., and for the 175 which were timed during the subsequent 45 min. it was 131·7 ± 2·2 μ/sec.

It is therefore possible, by means of this simple technique, to arrive at a value comparable with those obtained by more elaborate methods. Swimming-rates were also found to be similar when the semen was diluted to the same extent in a variety of other media such as Rothschild's medium[4], Baker's medium[5], isotonic saline buffered with phosphate, and seminal fluid.

The swimming-rate in cervical mucus, however, was considerably lower than in any other medium investigated. Twenty-five experiments were carried out with ten samples of mucus from eight cows and twelve samples of semen. The mean swimming-rates in these experiments varied from 22·0 to 80·7 μ/sec., and the mean of all the means was 56·2 μ/sec.

The mucus used in all these experiments had been stored for some time at −10° C. The possibility that freezing and/or storage might have produced deleterious changes in the mucus was checked by carrying out a further nine experiments with six different samples of mucus fresh from the cows, and six samples of semen. The range of mean swimming-rates in these nine experiments was 37·5–70·5, and the mean of the means 55·6 μ/sec.

It appears, therefore, that the swimming-rate of bull sperm in cervical mucus is only about a half of that which is usually adopted for calculations of the rate of movement in the female tract. It is still possible, however, that progress along a canal filled with mucus might be more rapid than along a comparable channel of saline. Because of the phenomenon of orientation in mucus[6], the sperm might travel in a straight line from one end of the cervix to the other, if the mucus were orientated in strands along it, whereas in saline the movement has the nature of a diffusion process.

This work is part of a programme supported by the Population Council, Inc., of New York.

Electron Microscopic Appearance of Close Relationships between Adult Guinea Pig Fibroblasts in Tissue Culture

1-CM. squares of full-thickness skin were aseptically excised from adult male guinea pigs. 10 days later explants of granulation tissue laid down in the wounds were cultured on plasma clot by the flying coverslip method. 36–48 hr. later, cultures were fixed intact in buffered osmium tetroxide or potassium permanganate, dehydrated with ethanol, and embedded in 'Araldite'. Parts of the fibroblast outgrowth were sectioned and examined in a Siemen's 'Elmiskop I' electron microscope.

Plasma membranes of adjacent cells ordinarily maintained a 100–200 Å. separation, but in places a more intimate relationship occurred. After osmium fixation (Fig. 1, top) it appeared as a quintilinear region ~ 160 Å. across. In permanganate fixed material (Fig. 1, bottom) the transverse dimension was similar, and the central dense line was twice as wide (about 40 Å.) as the two lateral dense lines.

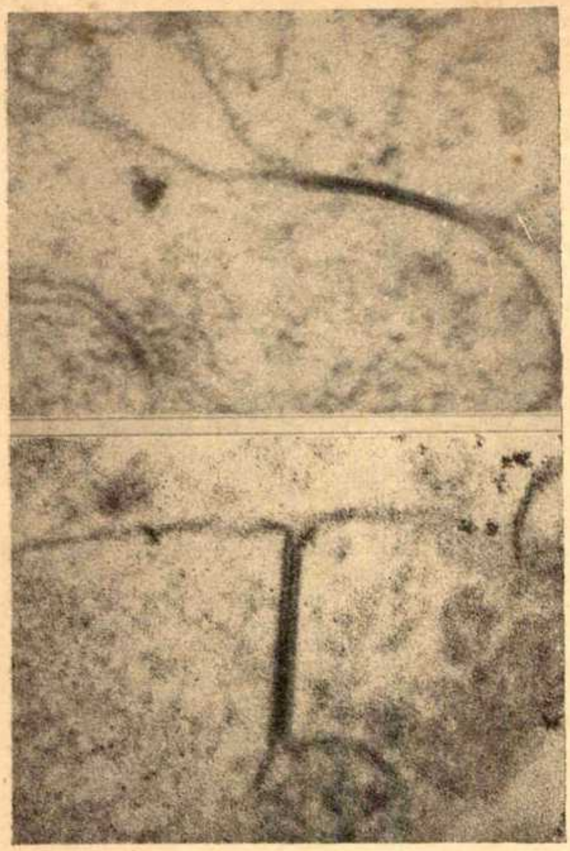

Fig. 1. Top: Osmium fixation (× 105,000); bottom, permanganate fixation (× 150,000)

Similar appearances have been reported for Schwann cell membranes by Robertson[1], who termed them "external compound membranes", and by Gray[2], who used the term "closed contacts", between glial processes and capillaries. Quintilinear regions of comparable dimensions have also been found in human cervical epithelium[3] and epidermis[4].

The functional significance of quintilinear close relationships between the plasma membranes of fibroblasts is as yet obscure, but they may be of importance for intercellular adhesion. It is of interest that Gray and Whittaker[5] found that 'closed contacts' of neuroglia remained intact after treatment of the tissue with isotonic and hypotonic sucrose.

Ability of the Trophoblast to destroy Cancer Tissue

THIS communication presents the results of some preliminary experiments which demonstrate that in the mouse the trophoblast can actively invade and destroy the tissue of a mammary cancer.

In 1902, Beard[1] first directed attention to the similarity between the destructive capacity of the trophoblast and that of cancer. Since that time, this feature of trophoblast has been the subject of many papers.

In many mammals, in the early stages of pregnancy, trophoblast, which develops from the implanting egg, infiltrates and erodes part of the uterine lining. When, as a result of this action, the conceptus is firmly attached to, or embedded in, the maternal tissue, the destructive capacity of the trophoblast normally diminishes and is finally lost. In some pathological conditions, however, its destructive phase proceeds unchecked, becoming truly malignant as the chorioepithelioma (for a comprehensive account of this subject see ref. 2).

It has been previously demonstrated[3,4] that the mouse egg, transplanted to the anterior chamber of the eye, gives rise to trophoblast which infiltrates and destroys the tissues of the eye. Also, Fawcett[5] showed that the trophoblast, arising from a mouse egg transplanted beneath the kidney capsule, invaded the kidney cortex.

I have also investigated the invasive behaviour of mouse trophoblast in a wide range of extra-uterine sites, and have shown: (*a*) that the sex of the host or the fact that the donor and host were of different strains did not affect the development or activity of the trophoblast[6]; (*b*) that mouse trophoblast, developing from a mouse egg transplanted beneath the kidney capsule of a rat, actively destroyed the kidney tissues[7]. This capacity of the trophoblast to withstand the immunological reaction of the host was partially explained by the recent findings of Hulka, Hsu and Beiser[8]. They showed how human trophoblast was able to absorb from the maternal circulation antitrophoblast antibodies; (*c*) that trophoblast can destroy some tissues (for example, spleen) exclusively by phagocytosis, while others (for example, testes) are destroyed by a cytolytic substance liberated by the trophoblast[9]. *In utero* trophoblast seems to use both methods of destruction; (*d*) the growth and invasive capacity of trophoblast is greatly accelerated by warmth and suppressed by cold[9]; (*e*) that trophoblast preferentially destroys tissues that have a high blood content[9]; (*f*) that in all the extra-uterine sites tested, active invasion by trophoblast persists for the same length of time as it does *in utero*.

A natural sequal to this series of investigations was to see whether the trophoblast was able to destroy cancer tissue. Transplantation of cancer cells to normal tissues has been extensively investigated; but no reference in the literature can be found to the transplantation, *in vivo*, of tissues in the opposite direction. However, normal cells (fibroblasts) have been introduced to cultures of cancer cells *in vitro*. The results vary. In some cases the cancer cells retarded the growth of the fibroblasts, and finally overgrew and destroyed them. Using other types of cancers the fibroblasts were stimulated to more rapid proliferation[10].

Runner[3] introduced, into the anterior chamber of the eye, mouse blastocysts together with small clusters of transplantable tumour cells. Of the three types of tumour cells used, two types (a spindle cell sarcoma and a carcinoma derived from the mammary gland epithelium) grew, and in these cases the blastocysts did not develop. The third type (a spindle cell sarcoma) was unable to grow in the eyes in which the blastocysts were developing. Runner does not mention any reaction between the trophoblast and the cancer cells.

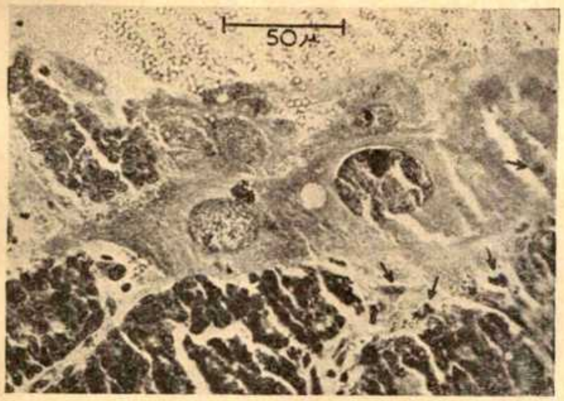

Fig. 1. Trophoblast containing one large and several smaller nuclei, invading the tumour tissue (bottom). The arrows indicate some of the individual cells of the tumour which have been ingested, while to the upper left a large cluster of tumour cells has been isolated by the infiltrating cytoplasm of the trophoblast. At the top can be seen part of the cavity aready eroded by the trophoblast

Of special interest are the results of some experiments performed in 1935 by Murphy[11]. He injected "extracts" of rabbit placentæ into the peritoneum of mice bearing mammary cancer. This produced marked regression of 26·7 per cent of the tumours, and complete absorption of a further 21·3 per cent. Normally less than 1 per cent of mammary cancers spontaneously regress. Murphy does not state what the placental extract was. It is surprising that such apparently important results seem never to have been followed up, nor indeed have they been critically discussed.

In the present series of experiments the tumours to which trophoblasts were transplanted were spontaneous mammary carcinomas occurring in the $C+$ strain of mouse. Each tumour was in a separate animal. The donor mice from which trophoblast was obtained were of a heterogeneous laboratory stock. Ectoplacental cones (the proliferative centre of the trophoblast measuring about 1/3 mm. in length) were extracted from the 7½-day-old conceptuses. One cone was introduced just below the surface of each of six tumours.

Five days later the host mice were killed and the tumours examined. The place to which the ectoplacental cone was transplanted was marked, in four of the six mice, by a prominent hæmorrhagic patch about 2–3 mm. in diameter.

Histological examination revealed that in these four tumours the ectoplacental cone had given rise to trophoblast giant cells, the nuclei of which were about 40μ in diameter (Fig. 1). The trophoblast had, in places, penetrated deeply into the tumour tissue, and most of it was distributed as a margin to a cavity in the tumour that the trophoblast had already eroded. This eroded cavity was not confused with the naturally occurring blood-filled cysts of the advanced mammary carcinoma. The actual process of destruction appeared to be by phagocytosis. The cytoplasm of the trophoblast, as it infiltrated, engulfed the tumour cells. These were afterwards broken down by intra-cellular digestion. The cavity eroded by the trophoblast contained extravasated blood and cellular debris.

The results of the preliminary experiments are encouraging and suggest a need for further investigation especially of the following aspects: the ability of the trophoblast to destroy hetero-specific mammary cancer, the fate of trophoblast transplanted to cancers other than the mammary carcinoma, whether trophoblast will destroy cancer tissue more readily than it will the contiguous non-malignant tissue, whether trophoblast cells in suspension can be introduced to the tumour via the blood stream.

These experiments are now in hand, and the results will be published at a later date.

Visceral and Eviscerated Carcass Fat of Adult Male Albino Mice

I have performed a series of experiments to see the effect of various doses of corticosterone, cortisone, and hydrocortisone on the visceral and eviscerated carcass fat[1].

The experimental animals were Holtzman male albino mice. As controls they were all given daily 0·05 ml. of Merck diluent (*CMC*), which was the vehicle of the glucocorticoids, for a period of 12 days. This treatment did not seem to have any influence on body-weight. When the animals were killed, their ages ranged from 89 to 96 days in the various groups. After the animals were killed, the stomach and intestines of each were completely evacuated and the contents examined for cestode parasites. This was deemed necessary because, in some previous experiments, mice from a number of animal houses were found to be highly infested with *Hymenolepis nana*.

The viscera of each animal were removed, weighed individually and mixed with 10 times their weight of anhydrous sodium sulphate. The mixture was homogenized in a mortar, and 5·5 gm. of the mass, corresponding to 0·5 gm. of the tissues, were weighed and transferred to a screw-cap vial. Thirty ml. of chloroform were added to the latter, the cap covered with aluminium foil and tightly screwed on. The vial was then shaken in a mechanical shaker for 24 hr. after which the mixture was filtered. Ten additional ml. of chloroform were added to the residue, and the resulting filtrate was combined with the previous one. The chloroform of the total filtrate was removed in a 'Rotovap' and the residue dried in a 60°–65° C. tissue-drying oven overnight and weighed.

This extraction procedure has been used previously by a number of investigators. Payne[2] found that it showed good correlation with the Soxhlet intermittent type of fat extraction on duplicate samples of mouse and rat livers of various fat concentrations.

The determination of the eviscerated carcass fat was carried out with essentially the same procedure except that the anhydrous sodium sulphate added was eight times the weight of the carcass, since the water content of the latter was less than that of the viscera. Afterwards, the mixture was passed through

Table 1. VISCERAL, EVISCERATED CARCASS, AND ENTIRE BODY FAT OF ADULT ALBINO MALE MICE

Exp.	No. of mice*	Fat (per cent) Eviscerated carcass	Visceral	Entire body	Total visceral fat / Total eviscerated carcass fat
(I)	4	9·55 ± 0·584	12·72 ± 0·486	10·35 0·486	0·453 ± 0·018
(II)	6	0·54 ± 0·634	13·97 ± 0·973	10·69 ± 0·730	0·506 ± 0·017
(III)	5	10·80 ± 1·820	15·80 ± 2·565	12·17 ± 2·055	0·539 ± 0·033
(IV)	6	12·16 ± 0·936	18·26 ± 1·54	13·78 ± 0·998	0·544 ± 0·052

* The average body-weights (gm.) in the four groups were: 40·0 ± 1·78; 39·9 ± 1·00; 34·9 ± 0·66; and 38·9 ± 0·35, respectively.

a Hobart meat grinder several times, then mixed in a Hobart mixer and afterwards transferred to a mortar and homogenized. An aliquot corresponding to 0·5 gm. carcass was taken and treated in the same manner as the visceral aliquot.

The results are given in Table 1. The last column indicates the ratio of the total visceral fat to the total eviscerated carcass fat.

The results of the analysis of the visceral and eviscerated carcass fat of the first three groups indicate rather close similarity. However, the animals of the fourth group show a considerably higher fat content, both in the viscera and body wall. It is pertinent to point out here that the animals in group I were killed in December, in groups II and III in January, while those in the fourth group in May.

Humoral Nature of Osteogenic Activity of Transitional Epithelium

THE osteogenic activity of transitional epithelium was discovered in the course of ligation of the renal artery[1] and bladder mucosa transplantation[2]. In both cases bone is induced in connective tissue along the line of contact with invading cells of hyperplastic transitional epithelium[3]. The question arises whether direct physical contact is required for induction, or whether transitional epithelium contains some diffusible substance with osteogenic activity which may act as an inductor well away from epithelium. All efforts to induce osteogenesis with cell-free extracts and homogenates of bladder mucosa have until now been unsuccessful. The same applies to the products of transitional epithelium secretion which occurs under the experimental conditions. In such experiments only extramedullar mielogenesis was induced[4].

In the experiment described here, homografting of the transitional epithelium within diffusion chambers was performed. The results obtained indicate that transitional epithelium actually contains some chemical substance which can diffuse outside the epithelial cell and stimulate osteogenesis without cell contact.

Diffusion chambers[5] consisted of two 'Millipore' filters (type HA = $0·75\mu \pm 0·02\mu$, 150μ thick). 5×10^4 cells in Hanks's solution were placed in each chamber. The cells were obtained by treating minced urinary bladder mucosa with trypsin or from whole bladders inverted so that the mucosa was exposed to the trypsin. Suspensions consisted of epithelial cells with small amounts of connective tissue cells. The chambers were implanted subcutaneously in adult guinea pigs. 30–35 days after implantation, the chambers with surrounding connective tissue were removed, fixed in 80 per cent alcohol and embedded in paraffin. Serial sections were stained with periodic acid–Schiff hæmatoxylin and Gomori's stain for alkaline phosphatase.

Transitional epithelium was found in 12 of the 20 intact chambers removed. In 8 of these 12 chambers bone formation was present on the host side of the filters. In no case were epithelial cells present outside the chambers, neither was osteogenesis observed around the chamber without growing transitional epithelium inside the chamber (46 chambers with different contents which were fixed on the 25th–52nd day).

Inside the chamber large membranes of growing epithelium were present (Fig. 1 *A*). They represented well-differentiated transitional epithelium with three layers of cells each having different histochemical characteristics typical for that layer of transitional epithelium[3] (Fig. 1 *A*, *B*).

The differentiation of epithelium and histogenetic factors acting in the chamber will be discussed elsewhere.

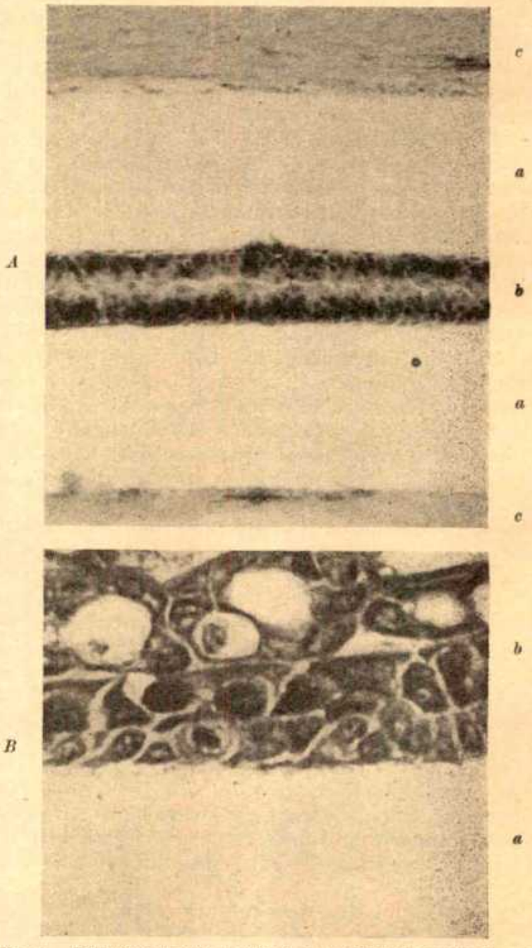

Fig. 1. Diffusion chamber with homografted transitional epithelium 30 days; alcohol. *A*, Gomori reaction (× *c*. 10); *B*, periodic acid – Schiff hæmatoxylin (× *c*. 10). *a*, Filter; *b*, epithelium inside the chamber; *c*, host connective tissue

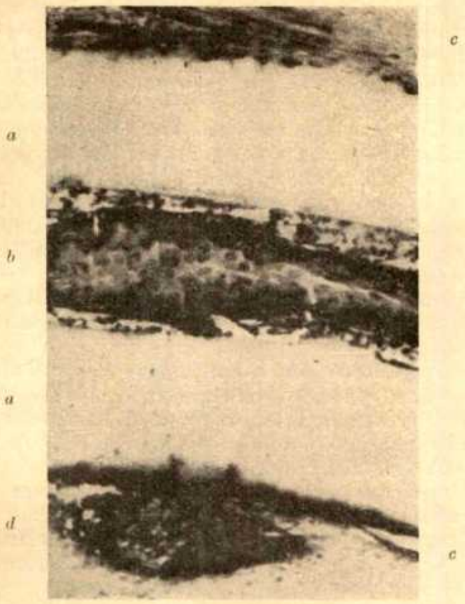

Fig. 2. Diffusion chamber with homografted transitional epithelium 35 days; alcohol. Gomori reaction (× *c*. 10). *d*, Bone tissue outside the chamber

In some cases inside the chamber not only epithelium layers but also connective tissue were growing without the two mixing. Osteogenesis inside the chamber was not observed. On the 30th day after implantation proliferation of host connective tissue around the chamber was obscure and the Gomori reaction was negative (Fig. 1 *A*). In this tissue distinct phosphatase-positive areas of typical osteogenesis could be recognized (Fig. 2). They were composed of osteoblasts and periodic acid–Schiff-positive bone trabeculæ (Fig. 3). Some of them were lying in close contact with the host surface of the filter (Fig. 2); the others were some distance from it (about 80μ) (Fig. 3). Osteogenesis was evoked on the host side of the 'Millipore' filter opposite the transitional epithelium occupying the inner surface of the filter. This transitional epithelium had a high content of glycogen.

The details of histogenesis of bone induction with the characteristics of connective tissue outside and inside the chambers as well as alkaline phosphatase and polysaccharide distribution in the filter itself will be described elsewhere. The results of other investigators and our own results show that the implantation of the diffusion chamber itself does not induce osteogenesis in the surrounding tissue. On the other hand, even the single epithelial cells can be easily recognized in the connective tissue, especially by using periodic acid–Schiff and Gomori reactions. This is why the absence of the epithelium outside the chamber and the intact character of the filters prove that the inductive influence originates only in the epithelium, lying inside the chamber.

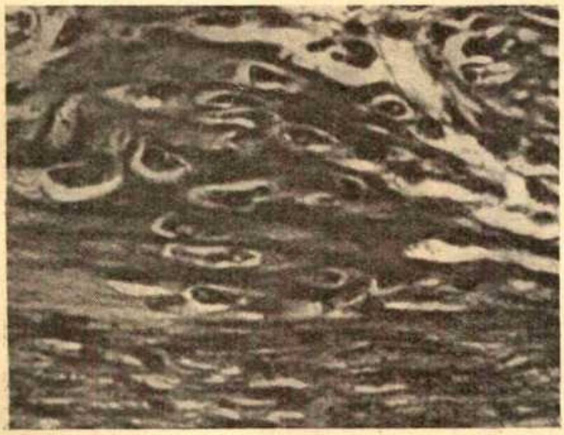

Fig. 3. Bone tissue induced in the host connective tissue outside the chamber 30 days; alcohol. Periodic acid – Schiff hæmatoxylin. (× *c*. 20)

Thus, the transitional epithelium induces osteogenesis by means of a cell-free substance which can diffuse through the filters in the same way as substances from the spinal cord[6] and osteogenic tissue[7] do.

It can be assumed that the transitional epithelium of normal urinary bladder produces and secretes the inducing substance in the same way as it did in the diffusion chamber. My results show that when epithelium is separated from vessels, it produces in the underlying connective tissue a concentration of inducing substance which is sufficient for osteogenesis at a distance of at least 150μ from the epithelium. Questions arise not only concerning the chemical nature of the inductor, but also its physiological significance (in particular, whether it is hormonal in nature[3]). The reasons why connective tissue growing inside the chamber as well as the urinary tract mucosa do not ossify are also of interest. It may depend on the tolerance to inducing influences of the connective tissue of the urinary tract. It may be, however, that in normal conditions the inductor is liberated predominantly in the vessels, or, on the contrary, excessive concentration of the inductor may not be effective. The investigation of these possibilities is now in progress.

Uptake of Water by the Lizard, *Moloch horridus*

Moloch horridus is an agamid lizard living in the desert regions of Western and South Australia. It weighs as much as 50 gm. and has been described by Buxton[1] as "a repulsive animal with tubercles and spines, it has the power of absorbing water through the skin after showers of rain". This ability of absorbing water through the skin is characteristic of many Amphibia and is correlated with a ready loss of water by the same route[2]. Reptiles living in arid conditions would find a water-permeable skin uneconomical for water conservation so that this mode of taking up water may be questioned for *Moloch*.

The following experiments were therefore made to investigate the uptake of water. This was estimated by changes in weight after the animal had been lying with its belly in water, the results being expressed as

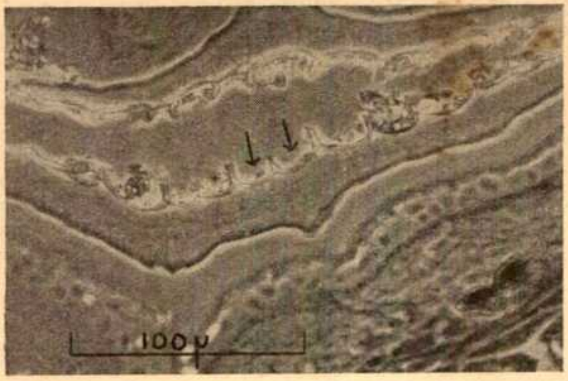

Fig. 1. Section through a skin fold showing the keratin ridges. Phase contrast photograph of a stained preparation. The arrows point to the channels in the keratin layer

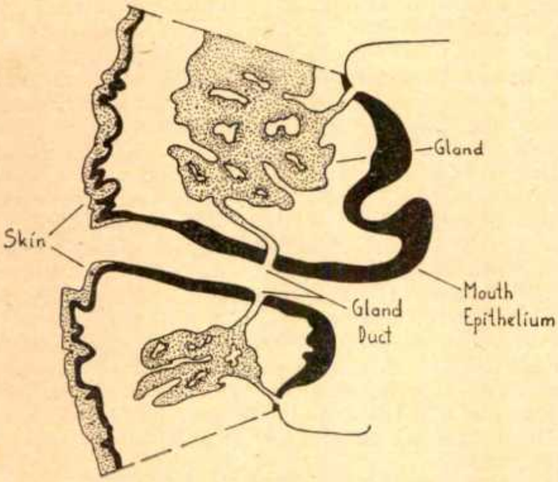

Fig. 2. Diagrammatic vertical section of the upper and lower lips reconstructed from stained serial sections

mean percentage gain in weight ± the standard error for six animals. Adequately hydrated animals, that is animals that had been allowed free access to water, when placed in water gained 2·68 (± 0·1) per cent in weight in the first 5 min. and did not gain thereafter. If, however, the animals had been made deficient in water by the intraperitoneal injection of 2 ml./100 gm. body-weight of 3 per cent sodium chloride 24 hr. before the experiment, then the gain in weight continued after the first 5 min. even though the animal did not drink in the usual manner. Thus after 95 min. the gain in body-weight was 5·6 ± 0·4 per cent and after 155 min. 6·5 ± 0·7 per cent. While the weight was increasing the jaws were noticed to be opening and closing and the significance of this was investigated by holding the jaws closed with adhesive tape. Then water-deficient animals, when lying in water, gained in weight an amount similar to the adequately hydrated animals (2·67 ± 0·1 per cent) in 5 min. and did not gain weight thereafter. If, however, the tape was removed, then the jaws started to move and a further gain in weight ensued.

During the first 5 min. the skin, like blotting paper, appears to absorb water and indeed an advancing water front can be seen moving over the skin. When the water reaches the mouth the water-deficient animals move their jaws and take in water. As confirmation, an animal deficient in water was allowed to lie in water containing a colloidal dye (Evans blue). Later the dye was found in the stomach despite the fact that drinking in the ordinary way was never seen.

The movement of water over the skin seems to be by capillarity along fine open channels in the outer keratinized layer of the skin. These channels are about 20μ across and are separated from one another by sharp keratin ridges (Fig. 1). The lips are well supplied with mucous glands some of the ducts of which open on to the opposable surfaces of the lips (Fig. 2). Possibly water from the skin on reaching the lip edges mixes with the hygroscopic mucus, is passed into the mouth and swallowed.

Ditmars[3] described what appeared to be absorption through the skin in another genus of agamid lizards, the *Uromastyx*. These lizards live in the desert regions of North Africa and South-West Asia and it seems likely that a mechanism may operate in these animals which is similar to that in *Moloch*.

The ecological significance of this mechanism may be that animals with an impervious skin suitable to the desert can still use it to collect water, from dew or sporadic showers, which is then swallowed.

Function of the Inferior Vena Cava Valve of the Harbour Seal

THE anatomical descriptions of the venous system of the seal have impressively described the large hepatic venous sinuses and the existence of a sleeve-like valve surrounding the inferior vena cava[1]. These hepatic venous sinuses are capable of holding a large volume of blood[1]. It has been tempting in the past to assume that the purpose of this anatomical system was to store a large volume of blood in the hepatic venous sinuses for use during periods of diving. This would require that the inferior vena cava valve impede flow of blood from the abdominal cavity during diving.

Five young female harbour seals (*Phoca vitulina*) were studied to ascertain the time of constriction of the inferior vena cava valve. They were maintained in live cars floated in the bay, fed fresh herring, and remained healthy throughout the period of investigation. The seals were trained to dive using a teeter-board tilted into an aquarium as previously described[2].

Advantage was taken of two anatomical features of the seal. Its jugular vein is rudimentary in nature and returns little blood from the cranial vault[1]. The major portion of the venous blood from the cranial cavity returns via the extradural vein (Fig. 1) and enters into the veins in the abdominal cavity by way of the renal venous plexus. A plastic cannula was threaded into the extradural vein through a thin-walled needle inserted through an area anæsthetized with 'Meticaine'. The cannula was then advanced to the level of the neck of the seal. Albumin labelled with iodine-131 and Evans blue were used as indicators and were either administered superior to the inferior vena cava valve by way of the fore flipper vein, or administered caudally to the vena cava valve by way of the renal venous plexus or the hind flipper veins.

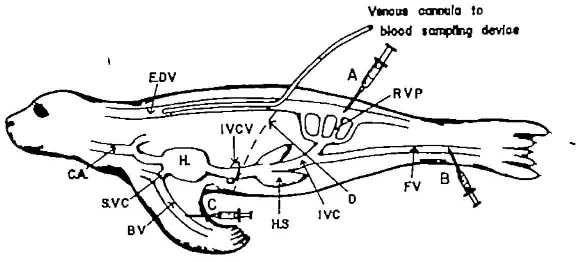

Fig. 1. Schematic diagram of vascular system and study technique. *B.V.*, Brachial vein; *C.A.*, carotid artery; *D.*, diaphragm; *E.D.V.*, extradural vein; *F.V.*, femoral vein; *H.*, heart; *H.S.*, hepatic sinuses; *I.V.C.*, inferior vena cava; *I.V.C.V.*, inferior vena cava valve; *R.V.P.*, renal venous plexus; *S.V.C.*, superior vena cava

A and *B* are injection sites below the level of the *I.V.C.V.*; *C* is an injection site above the level of the *I.V.C.V.*

Blood was sampled from the extradural vein catheter at 5-sec. intervals, and the appearance of the indicators was determined when the seal was out of water, submerged, and tilted without water in the aquarium.

Indicator administered into the fore flipper appeared in extradural vein blood in 20–25 sec., whether the animal was out of water or submerged. Albumin labelled with iodine-131 administered caudally to the inferior vena cava valve appeared in the extradural vein blood samples within 25 sec. of the time of injection when the animal was submerged, but the appearance time was delayed when the animal was out of water (Fig. 2).

The assumption that the inferior vena cava valve contracts when the animal dives does not fit practically the anatomical arrangement for the return of blood from the head to the venous system below the diaphragm. Harrison reported that the inferior vena cava valve is innervated by the phrenic nerve, and that the valve could be made to constrict by phrenic stimulation[3]. These findings by Harrison would be more compatible with function of the inferior vena cava valve during the time that the diaphragm is contracting.

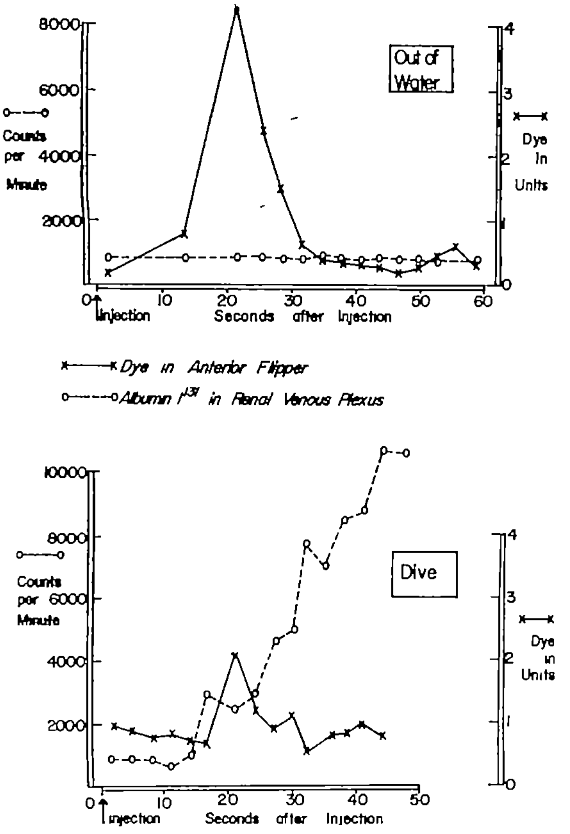

Fig. 2. Comparison of appearance of Evans blue and iodine-131 in the extradural vein in the same seal out of water and during diving. The high background at the time of injection of iodine-131 was due to previous determination of blood volume

The finding that indicator administered caudally to the inferior vena cava valve was delayed in appearance at the extradural vein is consistent with impairment of blood flow from the abdomen to the thorax when the seal is out of water. This finding is more consistent with the anatomical configuration of the venous system of the seal.

The seal breathes against a relative negative pressure when it swims with head above water due to the additional force of the water on the body of the animal. In such a situation, whether it be breathing against a continuous negative pressure, or standing in water up to the axillæ, the human being exhibits a brisk water diuresis[4,5]. It is believed that diuresis in man is due to displacement of blood into the thorax with diuresis resulting from atrial stretch receptor stimuli[4].

It would be a disadvantage to the seal to have blood displaced into the thorax when it surfaces to breathe. It is suggested that the function of the inferior vena cava valve of the seal is to restrict flow of blood from the abdomen to the thorax and prevent pulmonary engorgement with blood when the animal surfaces to breathe. The finding that continuous negative pressure breathing does not alter the rate of urine flow in the seal[6] would agree with this hypothesis.

Natural and Acquired Immunity Factors inhibiting Penetration of some Hexacanth Embryos through the Intestinal Barrier

EVIDENCE that immunity to tæniid infestations in the intermediate host may be encountered first when embryos attempt to penetrate the small intestinal wall soon after hatching was recently reviewed by Froyd and Round[1]. They were able by oral dosing with eggs of *Taenia saginata* to infect young calves, but not older animals, when the majority of the latter were already infected. They were able, however, to

Table 1. Average No. of Cysticerci of *T. ovis* in Sheep resulting from Injection and Challenge

establish infections in 13 of 26 older animals by subcutaneous and intramuscular injection of artificially batched and activated embryos. They suggested that the intestinal phase of immunity was thus successfully by-passed.

In preliminary experiments in this laboratory on resistance of the intermediate host to the hexacanth embryo, it has been found possible to infect previously unexposed sheep with *T. ovis*, *T. hydatigena* and *T. pisiformis* and rabbits only with the last-named parasite by intravenous injection of embryos hatched and activated by Silverman's[2] technique.

T. pisiformis has not been recorded in natural infections in sheep, and the establishment of this parasite by intravenous injection of activated embryos suggests that the intestinal wall of sheep may act as a natural barrier against penetration of embryos of this parasite when ingested by this host.

Table 1 shows that infections of *T. ovis* can also be established by intramuscular and subcutaneous injection of activated embryos. The number of cysts established increased with the dose of embryos given; it was greater by intravenous than by intramuscular or subcutaneous injection. However, the number 'taking' by these routes was always less than that by oral ingestion of eggs.

Twelve sheep injected intramuscularly or subcutaneously were afterwards challenged orally with 6,500 eggs. The average number of cysticerci which developed in sites unassociated with the site of injection was 6·2, whereas the average number was 63·0 in six control sheep given the same oral dose of eggs. There was some evidence that some of the cysticerci found in the vaccinated animals may not have been due to the challenge dose, but may have been carried from the site of injection, since two cysticerci were found in lymph nodes draining the injection site and in only two instances were lesions found in the head muscles, heart or diaphragm, whereas one or more of these sites in each control animal were infected.

Unlike *T. ovis* in sheep, cysticerci of *T. pisiformis* do not naturally develop in muscles, and rabbits injected intramuscularly or subcutaneously with hatched and activated embryos of *T. pisiformis* developed no cysticerci at the site of injection (Table 2).

Subsequent oral challenge with eggs of *T. pisiformis* in rabbits which had previously been injected with hatched embryos showed, as observed in the trial of *T. ovis* in vaccinated sheep, that few lesions developed from this challenge. An average of only 1·7 lesions was found in the liver of nine vaccinated rabbits, whereas the average number of lesions in the six controls was 113·2. Moreover, none of the few embryos which became established in the former reached maturity, whereas an average of eight viable cysts was found in the controls.

The results of these trials support the theory that immunity against the cystic stage of tapeworms has two parts: an early response, which may act at the intestinal level and be the more important, and a late response which acts at the site of predilection.

These results also suggest that both natural (species) and acquired (experience) immunity phenomena may occur at the intestinal level and that antibodies produced either against somatic antigens or, more likely, against the metabolic products of embryos undergoing a phase of intense activity during metamorphy are protective.

Whether or not embryos of different species produce common antigens is not yet known. But it appears likely that injection of homologous hexacanth embryos in one form or another may provide some degree of protection for the mammalian intermediate host against subsequent natural infections.

Relation between Chemical Composition and Nutritive Value of Uganda Grasses

In the various regression equations which have been published the relation between the percentage of crude fibre and the digestibility of organic matter was used[1-3]. Walker and Hepburn[3] used the percentages of crude fibre and crude protein to calculate the digestibility of crude protein, while Watson and Ferguson[4] calculated protein equivalent by using crude protein only. Glover, Duthie and French[5] also used percentage crude protein only, although this was later modified by Glover and French[6] for cases where there was an abnormal ratio of crude fibre to crude protein by proposing an equation using both crude fibre and crude protein. Watson and Ferguson[4] used the percentages of crude fibre and crude protein in their equation for the calculation of starch equivalent, while Mitchell[7] and Hallsworth[8] used crude fibre only.

Digestibility trials with zebu steers fed on various hays prepared from local grasses and on fresh grass have been carried out here in order to examine the relation between chemical composition of grasses, digestibility coefficients and starch equivalents.

The results of techniques and of some digestibility trials with zebu cattle have been published[8-12]. Ten digestibility trials, 7 of which were with *Chloris gayana*, *Cynodon dactylon*, *Panicum maximum* and *Themeda triandra* hays and 3 with freshly cut *Pennisetum purpureum*, have been completed, and the results show the following relation between chemical composition and nutritive values, which can be expressed by the following regression equations.

$$(1) \qquad Y = 139{\cdot}67 - 1{\cdot}0101\,x \quad r = 0{\cdot}9659 \quad P < 0{\cdot}001$$

where Y = digestibility coefficient of organic matter and x = percentage crude fibre + nitrogen-free extract or 100 − (percentage crude protein + percentage petroleum ether extract + percentage total ash).

$$(2) \qquad Y = 9{\cdot}588 + 4{\cdot}284\,x \quad r = 0{\cdot}9521 \quad P < 0{\cdot}001$$

where Y = digestibility coefficients of crude protein and x = percentage crude protein.

$$(3) \qquad Y = 119{\cdot}97 - 1{\cdot}0918\,x \quad r = 0{\cdot}9761 \quad P < 0{\cdot}001$$

where Y = starch equivalent and x = percentage crude fibre + nitrogen-free extract, or 100 − (percentage crude protein + percentage petroleum ether extract + percentage total ash). The protein content of fodders used varied between 4 and 17 per cent.

If these results are confirmed by work with a larger variety of roughages in subsequent digestibility trials it should mean that the cumbersome determinations of crude fibre can be eliminated, and to find out the full nutritional value it would be necessary to carry out analysis of crude protein, fat and total ash only.

It should be noted that in the organic matter regression equation the slope is very near 45° and for all practical purposes the factor 1·0101 is almost unity giving a very simple regression equation $Y = 140 - x$. A closer regression equation may be possible for proteins if hays and fresh fodder are treated separately. This should be confirmed by further trials.

We thank Mr. K. W. Harker for help in calculations.

Trapping the Airspora by Inhalation

Aerobiologists have developed various sampling techniques for investigating the concentration of airborne pollen and spores. The methods have been summarized by P. H. Gregory[1]. The gravity sedimentation methods on slides and Petri dishes have been superseded mainly by methods of sampling by impaction and allowing a quantitative estimation of the airspora for a given quantity of air. The two main principles of sampling by impaction are to move an object through air on a rotating device, that is, Rotorod sampler[2,3], or to draw the air by pumps, fans or aspirators through filters or on to slides. So far as I know none of the impaction methods trap spores by inspiration although such devices might give the nearest estimations of the number of particles inhaled. In these experiments air is drawn through the filter of a respiratory mask.

Volumetric investigations with the respirator sampler were carried out by adapting the 'Microfilter' dust respirator (Siebe, Gorman and Co., Ltd.). It comprises a moulded plastic face-piece and filter holder. A soft sponge rubber face pad and four elastic bands ensure tight fitting. The respirator is fitted with two valves, a non-return inlet and an outlet. Two perforated metal plates and a screwed plastic cover hold the filter in position. None of these features is changed for the experiment, but the filter pad of Merino wool and the muslin diaphragms are replaced by 'Fibroceta' (British Celanese), a very light wadding made from acetate fibres. The wide air spaces allow good air filtration and the impaction of the airborne particles on the fibres. This synthetic wool can be dissolved in acetone, thus avoiding the difficulties of washing off the impacted particles. Spores and pollen retain their shape in acetone.

In the present experiments a physiotherapist was breathing regularly through this respirator mask at a rate of 20 l./min. She was placed in a closed chamber where air was kept in motion by a high-speed fan. She inhaled for 30 min. During this period lycopodium spores were sprayed every 2 min. from an insufflator (total of 1 gm.). The insufflator was placed horizontally at a distance of 20 cm. from the filter holder and vertically 60 cm. above the filter holder. After 30 min. the filter was removed outside the chamber and dissolved in 200 ml. of acetone, leaving the spores and a fine granular material which could be easily distinguished from the spores when under the microscope. The acetone suspension was centrifuged and the precipitate suspended in 2 ml. of water. The number of spores contained in this suspension were counted in a hæmocytometer in a field of 1 sq. mm., depth of 0·1 mm. The number of spores per cubic metre of air was 133,300.

On advice of Dr. P. H. Gregory the efficiency of the respirator mask was tested by running a Rotorod sampler during the period of inhalation. The Rotorod sampler was placed at the same distance from the insufflator as the filter holder. The number of spores per cubic metre was 50,300. The lower figure of spores sampled by the Rotorod sampler may be due not to less efficiency but to overloading with spores in this experiment.

The new method of trapping the airspora by inhalation may prove to be a reliable and efficient technique, valuable in investigations of respiratory allergy.

I thank Dr. P. H. Gregory for discussion, loan of the Rotorod sampler and for estimating the deposition of lycopodium spores on the Rotorod sampler.

ENTOMOLOGY

Regulation of Water Economy in *Rhodnius prolixus*

IN a previous report[1], the existence in insects (*Anisotarsus, Blaptica*) of a neurosecretory regulating circuit was postulated in order to explain the regulation of water economy. Later experiments with *Schistocerca cancellata*[2] did not confirm Ramsay's hypothesis, as proposed for *Aedes aegypti* (control by means of the peristalsis of the hindgut[3]), but could be interpreted on the hypothesis that regulation occurs by a direct modification of the excretory activity of the Malpighian tubes, although other hypotheses were not excluded.

Table 1

	Water excreted as per cent of the water in ingested blood	Final volume of the lymph (mm.^{3})
Decapitated	15·4±3	45·2
Controls	51·7±5·4	19

$n = 30$ $P < 0{\cdot}01$

The following results were obtained recently with *Rhodnius prolixus*: (1) Fifth-stage larvæ, decapitated immediately (10–20 min.) after feeding, retained in their hæmolymph after 24 hr. a greater amount of the water contained in the ingested blood (73 per cent) than the non-decapitated controls (42 per cent). Normal elimination of turbid excrements rich in sediments occurred in both decapitated and control larvæ. (2) Similarly decapitated larvæ and controls were parabiotically attached at their heads. No reciprocal actions were observed. Transfusions also gave similar results. (3) The retention of water in the hæmolymph obtained by decapitation may be duplicated by plugging the anus. (4) If cannulated animals are used to avoid possible mechanical retention not due to the Malpighian tubes, the values given in Table 1 were obtained, 16–24 hr. after feeding (and decapitation).

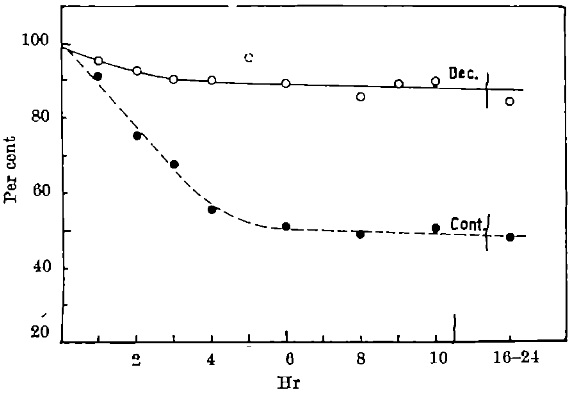

Fig. 1. ○, Decapitated; ●, controls

In Fig. 1, urine excretion (as percentage loss of weight of all the animals with respect to the amount of water contained in the ingested blood) is plotted against time.

Except for the inconclusive results given by parabioses and transfusions, the results reported here suggest that the disturbed water economy observed in the decapitated bugs is due to an abnormal functioning of the Malpighian tubes rather than to a simple modification of the peristaltic movements of the alimentary canal or to mechanical blocking of the anal spincter.

Identification of Geraniol as the Active Component in the Nassanoff Pheromone of the Honey Bee

HONEY bees (*Apis mellifera* L.) attract each other by a variety of biological stimuli. The olfactory stimulus produced by the worker bees has received attention during a number of investigations ever since Sladen[1] suggested that the attractant odour originated from a special organ discovered by Nassanoff in 1883. This scent organ is located on the anterior part of the seventh abdominal tergum of the worker bee.

Sladen[1] observed bees at the hive entrance with their abdomens elevated, exposing the scent organs. The bees fanned air over the scent organs, thus dispersing the odour. Von Frisch and Rösch[2] found that foraging bees exposed their scent organs at flowers if these yielded an abundant supply of food. Because of the alluring effect which this secretion of the honey bee has on members of the same species it has been included in a group of biologically active substances termed 'pheromones'[3].

A hive-specific body odour is usually superimposed on the scent from the Nassanoff organ. However, Renner[4] obtained the Nassanoff pheromone free of interfering body odours by wiping the exposed scent organ with small bits of filter paper. He showed that the Nassanoff pheromone was not specific for race and colony.

Chemical identification of the active principle of the Nassanoff pheromone could have significant influence on modern agricultural practices dealing with insect pollination of fruit and seed crops.

The pheromone was absorbed on bits of Whatman No. 1 paper following Renner's wiping procedure. The scent obtained on the wipes from individual bees varied both in quality and quantity. Some wipes had a dry odour different from the sweet fruity odour characteristic for the normal wipes. Controls were prepared by wiping body areas other than the scent organ.

In two-choice olfactometer experiments more bees were attracted by odoriferous wipes than by controls. Wipes with dry odour attracted fewer bees than those with fruity odour, which indicated that the attractant principle of the Nassanoff pheromone was associated with its fruity odour.

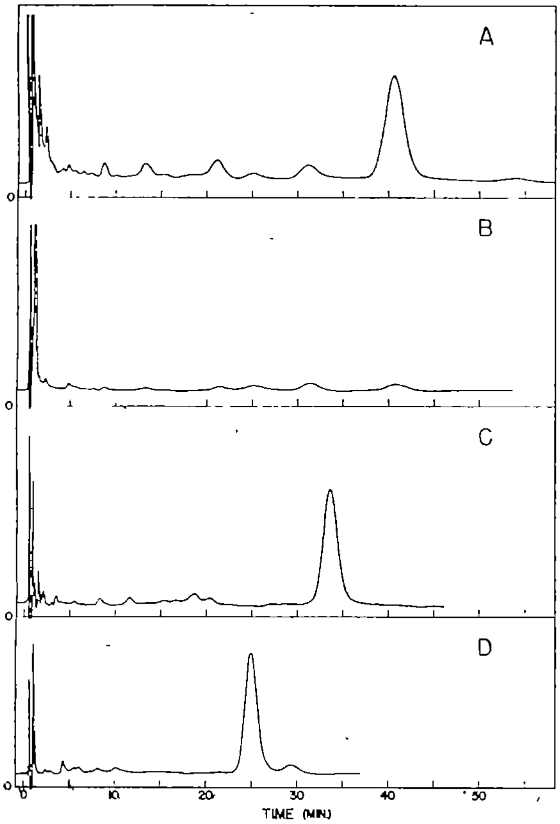

Fig. 1. Gas chromatograms of extracted Nassanoff pheromone on a diethyleneglycol succinate polyester column at 110° C. (*A*), on a 'Carbowax' 1,500 column at 130° C. (*C*), and on a silicone 550 column at 120° C. (*D*). An extract lacking the characteristic odour was also chromatographed on the diethyleneglycol succinate polyester column (*B*)

Thirty wipes which exhibited the characteristic fruity odour were extracted with 20 μl. of carbon disulphide. Centrifugation yielded approximately 12 μl. of a yellowish solution. A 5-μl. portion of this solution was chromatographed in a Perkin–Elmer 154*C* vapour fractometer equipped with a hydrogen flame ionization detector. Using a 4½ ft. × ⅛ in. column containing 10 per cent of diethyleneglycol succinate polyester on 160–170 mesh 'Anakrom *U*' solid support at 110° C., the chromatogram Fig. 1*A* was obtained. Similar treatment of wipes exhibiting the non-characteristic dry odour produced the chromatogram in Fig. 1*B*. The controls gave an almost flat curve (not shown). Thus, it is evident that the characteristic fruity odour must be due to the main component in Fig. 1*A*. Fig. 1*C* is the chromatogram of the characteristic bee material, run at 130° C., using 10 per cent of 'Carbowax' 1,500 as the liquid phase, and Fig. 1*D* is that using 10 per cent of silicone 550 plus 1 per cent of diethyleneglycol succinate polyester to reduce tailing, and run at 120° C.

Using Brown's technique[5], in which the 'affinity fractions' are plotted on triangular co-ordinates, it was determined that the main component of the characteristic bee material was most likely an alcohol. The retention times of this main component on each of the columns were identical with the retention times of geraniol run on the same columns. On all three columns the isomer nerol had shorter retention times than geraniol and was readily separated from it.

The characteristically smelling wipes from 500 bees were extracted and the extracts subjected to gas chromatography using the diethyleneglycol succinate polyester column. Only a small fraction of the effluent from the column was led to the detector. The main component was trapped and transferred in carbon disulphide solution to a 0·1 mm. ultra-micro cavity cell. The infra-red spectrum (Fig. 2*A*) was obtained on a Perkin–Elmer model 21 spectrophotometer using a lens-type beam condenser. This spectrum was identical with a spectrum of geraniol (Fig. 2*B*) obtained in the same way, and different from nerol. The broad peak at 3,300 $cm.^{-1}$ in Fig. 2*B* results from use of a higher concentration of geraniol. Identical shifts of peaks in the infra-red spectra were observed after bromination of both the bee component and pure geraniol.

A comparison of the gas chromatographic peak areas indicated that the wiping procedure yielded, on the average, about 0·25 μgm. of geraniol per bee.

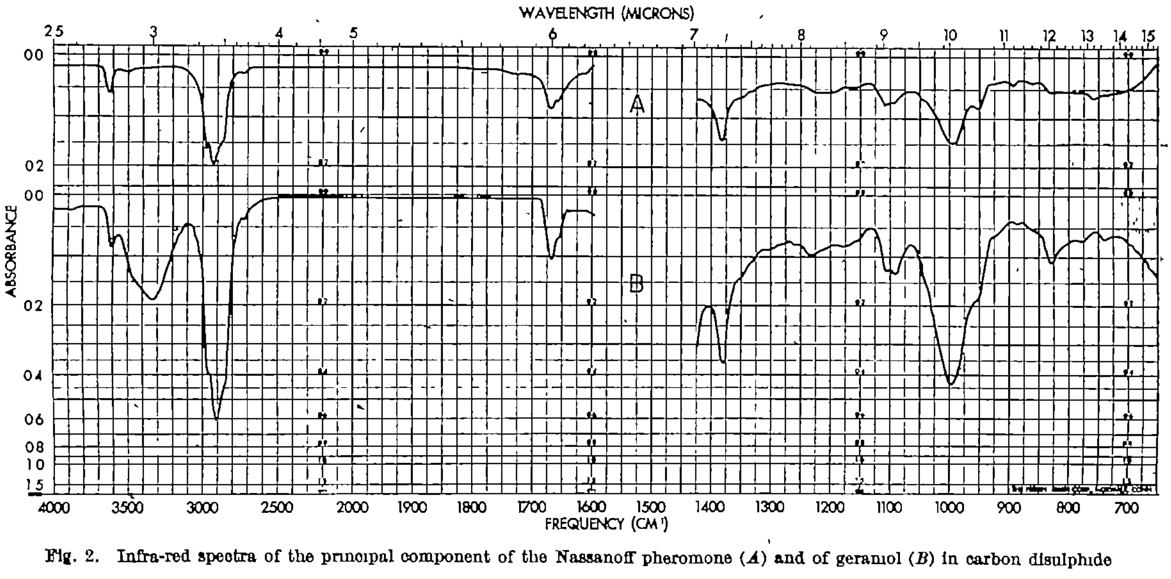

Fig. 2. Infra-red spectra of the principal component of the Nassanoff pheromone (*A*) and of geraniol (*B*) in carbon disulphide

Pyrophosphate esters of geraniol have been identified as intermediates in the synthesis of squalene from acetate in the rat liver enzyme system[6]. However, this is the first reported occurrence of free geraniol in animal secretions.

An Aphid Flight Chamber

In studying the settling responses of winged aphids and their reactions to different host conditions it is desirable to use insects which have flown freely. Kennedy[1] mentioned a chamber for giving single aphids flight exercise, and the same author[2] has recently described a modified apparatus for maintaining a swarm of flying aphids for experiments on optomotor attraction.

In the chamber described here a large number of aphids can be allowed to take off, fly freely and alight naturally on plants.

The chamber (Fig. 1) is made of hardboard bolted to an angle iron frame, the inside walls, roof and floor being coated with blackboard paint. The floor is raised off the ground so that the observer can sit in the hatch. A 12-in. aerofoil fan blows air into the chamber through a cloth screen on the bottom of a box set in the roof. The cloth screen is of blue terylene with 100 threads of about 105μ diameter per inch. The box has two sloping glass sides; above each are hung two 400-W. high-pressure mercury fluorescent lamps (not shown in Fig. 1) which shine into the chamber through the glass and cloth. Air speeds measured within the chamber are 2 ft./sec. 3 in. below the cloth, 1·5 ft./sec. 12 in. below and 0·5 ft./sec. 24 in. below.

Fig. 1

Myzus persicae last-instar nymphs are put on tobacco seedlings in 1-in. pots on the stand on the floor of the chamber; about 150 pots can be accommodated. After the last moult and on completion of the teneral period, the aphids have taken off and flown for up to 85 min., alighting again on the plants and settling down to reproduce. Most first flights have lasted between 40 and 70 min. The aphids fly at varying heights between one and four feet from the floor of the chamber. The mean height at which they fly seems to depend on their size and for very large ones the airflow has to be increased slightly. Generally all aphids reared under the same conditions fly at the same height and it is not necessary to adjust the fan speed during the course of an experiment.

GENETICS

Variation of Bristle Number in Relation to Speed of Development in *Drosophila melanogaster*

The bristle number of the fourth and the fifth abdominal segments of *D. melanogaster* is interesting for two reasons:

(1) The character has been examined extensively in quantitative genetics[1-3].

(2) Bristles are connected with bipolar cells of the nervous peripheral system[2,4] and as such they parallel morphogenetic variations of the tangoreceptor organ, in so far that variations in the area studied reflect variations on the whole body surface.

Some authors[2,3] have attributed the fluctuation of bristles to a low number of genes while a residual variation is imputed to the so-called 'genetic background'. The residual variation requires further definition. Since it is considered to reflect a variation in the development of the nervous system, it could possibly be linked with such a fundamental trait as duration of development.

In order to verify an eventual relation between bristle number and development time a hundred pairs from the stock Canton Special, hatched within 10 hr., were collected. Considering the results of Durrant[5], eggs were procured from flies of a given age, namely, 5 days after pupal hatching. These flies were allowed to lay on the same medium for 14 hr. and discarded afterwards. The eggs were maintained at 25° C. and the pupal hatchings regularly recorded. The correlation coefficients between bristle number and duration of development were found to be $-0{\cdot}281$ ($P < 0{\cdot}01$) for the males and $-0{\cdot}344$ ($P < 0{\cdot}01$) for the females. The difference between these coefficients is not significant. In fact, this relation was not retained because the use of speed of development, that is, the reciprocal of duration of development, leads to a better fit (Fig. 1). Using time of development, the ratios of the variance due to regression on the residual variance are 27·9 (males) and 44·8 (females). These variance ratios increase to 34·1 and 47·4, that is, the fitting of the regression increases in

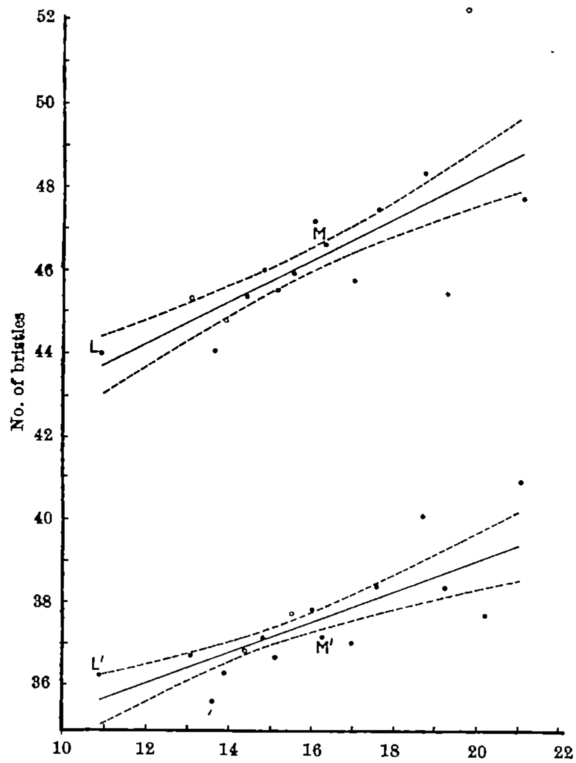

Fig. 1. Relationship between bristle number and developmental speed. Heavy lines, females; thin lines, males. Continuous lines, observed regression line; broken lines, range within which the true line is located with a probability of 95 per cent

this proportion when development speed is used instead of development time. Similarly, the correlation coefficients are slightly augmented to + 0·308 and + 0·353. The 95 per cent probability range of the regressions[6] is quite narrow and points to a very strict dependence of bristle number on speed of development. The question then arises as to whether the variation of bristles due to lower or higher developmental rates is transmissible. It is known that speed development in *D. melanogaster* has a hereditary component[7], and, further, that numbers of bristles are generally resistant to environmental modification[4]. However, on the basis of my experiments, the genetic causation of the correlative behaviour of numbers of bristle and speed of development cannot be proved.

In any event, the facts disclosed show a strong correlation of speed of development with number of bristles and therefore with the development of the tangoreceptor system. This correlation might be genetic and morphogenetic or it might be due to a parallel modification of both traits under the influence of staling culture medium. Whatever explanation is valid, the facts show sufficiently that in genetic studies of number of bristles more emphasis should be placed on sampling techniques with respect to speed of development.

Hybrid Vigour and Inheritance of Height in Rice

PREVIOUSLY[1], while investigating the inheritance of photoperiodic reaction in rice, in this laboratory it was observed that the F_1 plants of the crosses between Aus (summer) and Aman (winter) varieties of rice showed hybrid vigour in respect of plant height, tiller number and grain yield. Earlier workers[2] also recorded hybrid vigour in the F_1 generation of some rice crosses. However, it is interesting to note that in the present investigation this vigour in one of the growth characters, that is, height, was found to persist in the F_2 generation (Table 1). Mean height of the F_2 plants in every case was found to exceed the mean height of the taller parent. The F_2 frequency distribution in each cross indicated mostly a unimodal curve with transgression beyond the maximum limit reached by parents. It was also observed that the number of the F_2 plants exceeding the maximum limit of the parents was proportionately more in crosses which involved parents with almost the same maximum limit in height, that is, in Patnai-23 × Dhairal and Bhasamanik × Charnock crosses. While in other crosses involving parents with comparable maximum height, as in Patnai-23 × Charnock or in Bhasamanik × Dhairal crosses, the proportion of transgressing segregation in F_2 was less. All these indicate a polygenic inheritance of this character. The proportion of the F_2 plants exceeding the maximum limit of the parents under different crosses

suggests that the cumulative effect of the genetic complex influencing the plant height is different in different varieties. Several workers observed the quantitative nature of this character, while monogenic, digenic and trigenic segregations were also reported in some crosses[2].

Due to the influence of hybrid vigour and gene complexes on the expression of the plant heights, the inheritance of this character in the present investigation has become very complicated. Further investigations are required to throw more light on this aspect.

I thank Prof. P. K. Sen, Department of Agriculture, University of Calcutta, for his help.

VIROLOGY

A Rapid Method for Microanalytical Determination of the Amount of Tobacco Mosaic Virus in Plant Tissues

THE development of the kinetic studies of virus biosynthesis requires an accurate and rapid method for determining the amount of virus nucleoprotein contained in small samples of tissue. Bancroft and Curtis[1] described a simple method which utilized trichloroacetic acid (TCA) as the substance for precipitating and extracting virus nucleic acid. Although this method is rather rapid, it results in the destruction of virus nucleoprotein and demands careful attention to the final concentration of TCA, because TCA itself has a high absorbance at 260 mμ which may cause gross errors in the measurement of the small amount of viruses. The disadvantages of the method were overcome by using ammonium sulphate instead of TCA: the accuracy and rapidity of the method were also increased.

One to ten disks of tobacco leaves infected with the virus (9 mm. diam.) were homogenized with 6 ml. of distilled water. 5 ml. of the homogenate and 2 ml. of chloroform were mixed and shaken for 5 min., cooled at 4° C. for 15 min. and then centrifuged at 3,000 r.p.m. for 15 min. 4 ml. of the resultant supernatant were transferred into a centrifuging tube, to which 1·33 ml. saturated ammonium sulphate was added (0·25 saturation) at room temperature. The mixture was thoroughly stirred until the precipitate produced had almost disappeared, and then allowed to stand for 10 min., followed by 15 min. centrifugation at 3,000 r.p.m. The resultant precipitate was dissolved in 4 ml. distilled water, stood for 10 min., and centrifuged at 3,000 r.p.m. for 15 min. The optical density at 260 mμ of the supernatant was measured using a spectrophotometer.

The absorption spectrum of the supernatant is shown in Fig. 1. The curve was found to be approximately the same as that of Reddi[2]. It is clear from Fig. 2 that measurement of tobacco mosaic virus by this method is not disturbed by the presence of normal protein of host tissues. The infected leaf tissues were homogenized with 20 times their wet weight of distilled water and the homogenate of healthy tissues was added. The virus concentration of these homogenates was determined by the present method. No. 6 on the abscissa in Fig. 2 shows the presence of infected homogenate only and No. 0 shows that of normal ones only. Nos. 1–5 represent the mixed homogenates containing 1/6–5/6 of infected homogenate to total volume respectively. It was found that the optical densities of the nucleoprotein increased in a straight line according to the increase of the amount of infected homogenate in spite of the presence of healthy homogenate.

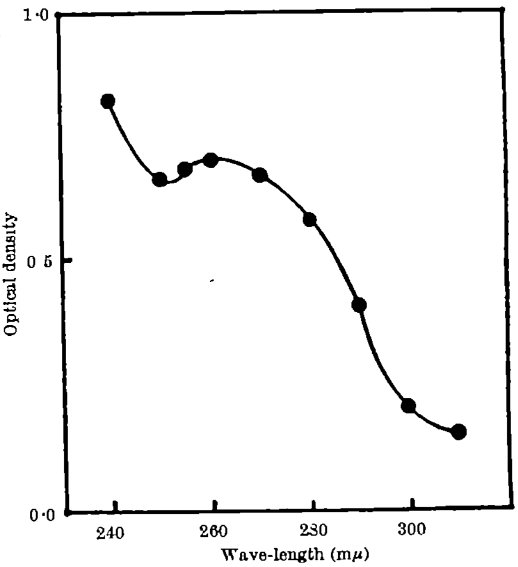

Fig. 1. Absorption spectrum of tobacco mosaic virus

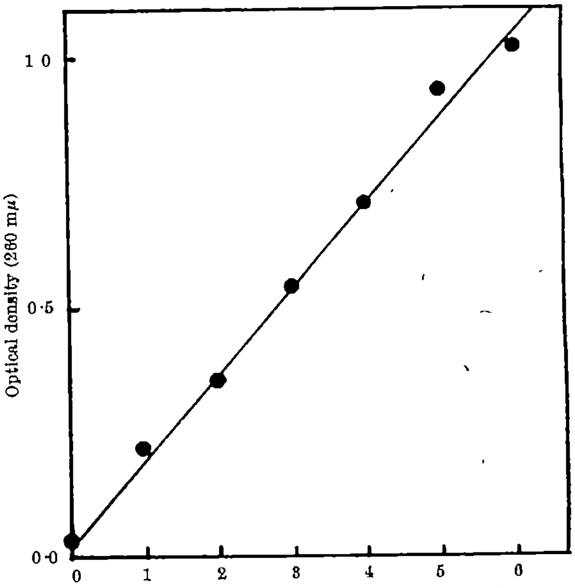

Fig. 2. Optical densities of the nucleoprotein obtained from infected leaf homogenates in the presence of healthy leaf homogenates

This method will be applied to the rapid determination of this virus in the very small quantity of samples.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Research Fellow (with a first degree in biochemistry, chemistry or botany, and research in biology) in Plant Biochemistry in the Department of Botany, to participate in research on the mechanism of photosynthesis—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (May 25).

Assistant Lecturer or Lecturer (with qualifications in any branch of pure mathematics, numerical analysis or statistics) in the Department of Mathematics—The Registrar, University College of South Wales and Monmouthshire, Cathay's Park, Cardiff (May 26).

Lecturer (Grade II, preferably at least 30 years of age) in the Department of Physics, The Registrar, The University, Bristol (May 28).

Lecturer in the Department of Mechanical Engineering—The Secretary, University College, Gower Street, London, W.C.1 (May 28).

Lecturer (Grade II) in Physiology—The Registrar and Secretary, The University, Bristol (May 30).

Lecturer in Psychology at Rhodes University, Grahamstown, South Africa; and a Lecturer in Psychology at Rhodes University, Port Elizabeth, South Africa—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa and London, May 31).

Research Demonstrator (graduate in botany) in the Department of Botany, to engage in research, preferably in plant physiology and biochemistry, plant pathology or ecology—The Registrar, University College, Singleton Park, Swansea (June 2).

Junior Lecturer (with interests in the fields of either physical or organic chemistry) in Chemistry—The Registrar, Trinity College, Dublin, Republic of Ireland (June 4).

Lecturer or Junior Lecturer in Biochemistry—The Registrar, Trinity College, Dublin, Republic of Ireland (June 4).

Assistant Lecturer (man or woman with a special interest in petrology) in Geology—The Secretary, Bedford College (University of London), Regent's Park, London, N.W.1 (June 8).

Lecturer or Assistant Lecturer (Probationary) (man or woman graduate, preferably with experience in experimental high energy or nuclear physics) in Physics—The Secretary, Bedford College (University of London), Regent's Park, London, N.W.1 (June 8).

Leverhulme Lecturer (medically or non-medically qualified) in Parasitology—The Registrar, The University, Liverpool, quoting Ref. CV/78/T (June 8).

Lecturer or Assistant Lecturer (with special qualifications in some aspects of the systematics or comparative morphology of vascular plants) in Botany—The Secretary and Registrar, The University, Southampton (June 9).

Temporary Botanist or Agriculturist, to assist in work on diseases of potato tubers—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (June 15).

Assistant in Organic, Physical or Inorganic Chemistry at Queen's College, Dundee—The Secretary, University of St. Andrews, c/o Queen's College, Dundee (June 16).

Lecturer (with experience in the field of rheology or some other section of industrial physics) in Applied Physics at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, June 18).

Lecturer (with an honours degree in physiology, pharmacology or pharmacy) in Pharmacology; Demonstrators (2) in Pharmaceutics; a Demonstrator in Pharmacognosy; and a Demonstrator in Pharmaceutical Chemistry—The Registrar, The University, Nottingham.

Postdoctoral Biochemist or Protein Chemist, for fractionation and investigation of coagulation factors in plasma—Dr. G. B. D. Scott, Department of Morbid Anatomy, Royal Free Hospital, Gray's Inn Road, London, W.C.1.

Scientific Information Officer (Abstractor) (with a degree in agriculture or natural science, and able to translate from German)—The Director, Commonwealth Bureau of Pastures and Field Crops, Hurley, Berkshire.

Senior Laboratory Technician I in Hæmatology at the Connaught Hospital, Walthamstow, London, E 17—The Secretary, Forest Group H.M.C., Langthorne Road, Leytonstone, London, E.11.

Student Technician in the Department of Pathology, Connaught Hospital, Walthamstow, London, E.17—The Secretary, Forest Group H.M.C., Langthorne Road, London, E 11.

GEOPHYSICS

Atmospheric Blow-up at the Auroral Zone.—Dr. K. D. Cole 761

PHYSICS

Optical Refractivity of Free Electrons.—S. A. Ramsden and E. A. McLean 761
Electron-Hole Scattering at High Injection-Levels in Germanium.—L. W. Davies 762

CRYSTALLOGRAPHY

Crystal Growth and Cell of Cellotriose.—Dr. W. G. Ferrier 763
Optical Fourier Synthesis for Non-centrosymmetric Projections of Crystal Structures.—Dr. G. Harburn and Dr. C. A. Taylor 764
Structure of Calcium Aluminate, $12CaO.7Al_2O_3$.—J. Jeevaratnam, Dr. L. S Dent Glasser and F. P. Glasser 764

METALLURGY

Dendritic Growth of Graphite from Melts.—Dr. I. Minkoff and I. Einbinder 765

RADIATION CHEMISTRY

Radiation Decomposition of Sodium Chlorate.—P. F. Patrick and Prof. K. J. McCallum 766
Electron Spin Resonance in γ-Irradiated Deoxyribonucleic Acid.—C. Dorlet, A. van de Vorst and Dr. A. J. Bertinchamps 767

CHEMISTRY

Catastrophic Failure of Stressed Polyethylene Terephthalate.—R. P. Sheldon 767
A Total Resolution of Aspartic Acid Copper Complex by Inoculation.—Kaoru Harada and Prof. Sidney W. Fox 768
Thin-Layer Chromatography of Nucleotides on Layers of Cellulose Ion-Exchangers.—Dr. K. Randerath 768
Melting Point of *p*-Bromophenacyl Formate.—Dr A. C. Neish 769

BIOCHEMISTRY

Structure of Feroverdin —A. Ballio, H. Bertholdt, Prof. E. B. Chain, F R.S. and V. Di Vittorio 769
Inhibition of Hyaluronidase by Urinary Kallikrein.—Dr. George H. Warren, Joseph Seifter and Jerome M. Glassman 770
Separation of Lecithin and Phosphatidyl Ethanolamine by Chromatography on Paper impregnated with Zinc Salts —R. Collier 771
L-Glutamate Dehydrogenase Isoenzymes.—Dr. H J. van der Helm 773
Heat-Coagulation of Edestin.—Prof. P. Putzeys and L. Mahieu 773
Presence of Indole Compound in Nematode Galls.—M. Balasubramanian and Dr. G. Rangaswami 774
Tryptophan and Indole Compounds in Banana Ovaries.—K. G. Shanmugavelu and Dr. G. Rangaswami 775

PHYSIOLOGY

Afferent Cutaneous *C*-fibre Reactivity to Repeated Thermal Stimuli.—Ingrid Witt and J. P. Griffin 776
Potentiation by Anæsthetics of Brain Damage due to breathing High-Pressure Oxygen in Mammals.—H. A. S. van den Brenk and Dana Jamieson 777
Effect of Mucopolysaccharides and Colloid on the Function of the Thyroid.—Prof. St. Krompecher, M. B. László and É. H. Oláh 778
Effect of Additions of Sodium and Potassium and of Peritoneal Dialysis with a Hypotonic Solution of Sodium Chloride on the Sodium and Potassium Contents of the Maternal and Fœtal Serum and the Amniotic Fluid of Rats.—H. Winkler, S. Theil and Prof. E. Goetze 779

PHARMACOLOGY

An Antigen in Malignant and in Embryonic Tissues.—Prof. G. A. H. Buttle, O.B.E., Jean L. Eperon and Eva Kovacs 780
Rapid Hepatic Shift of Worms in Mice infected with *Schistosoma mansoni* after a Single Injection of Tartar Emetic.—Prof. G. A. H. Buttle, O B E, and M. T. Khayyal 780

RADIOBIOLOGY

Whole-Body Oxygen Consumption during Irradiation for the Survival of Rats after Exposure to X-rays.—Dr. Antonin Vacek 781
Radiation Protection with Sulphur and Some Sulphur-containing Compounds.—Prof. A. Charlesby, P. G. Garratt and P. M. Kopp 782
Experimental Oxidation of Hæmoglobin Effects of Irradiation in Rats.—Dr. W. K. Metcalf 783
Dose Effect Curve of Somatic Mutations in *Ephestia kuhniella* Z. for Low Dose-range (0–200 r.).—Dr. I. Muller, E. A. Löbbecke and O. Oltmanns 783

BIOLOGY

Dry-Mass Distribution of Bone Marrow Free Cell Population in the Mouse as determined by Interference Microscopy.—Hun Lee, Dr. Victor Richards and Arthur Furst 784
Reciprocal Transplantation of Blastocysts between Rats and Mice.—D. R. S Kirby 785
Brood-production after Hypophysectomy in the Viviparous Teleost *Mollienesia latipinna* Le Sueur.—Dr. J. N. Ball 787
Interaction of 6-Methylaminopurine and Adenine in Division of Soybean Cells.—Prof. Carlos O. Miller 787
Effect of Temperature on *in vitro* and *in vivo* Reactions of Diethyl Sulphate.—R. E. Heiner, Prof. C. F. Konzak, R. A. Nilan and H. Bartels 788
Fluorophenylalanine as a Systemic Fungicide.—O. M. van Andel 799
Preparations of Cell-Walls of Some Fungi.—Maria José R. Aguirre and Dr. Julio R. Villanueva 791
Some Fossil Chelonian Fragments from Makapansgat.—Dr. D. G. Broadley 791

MICROBIOLOGY

Morphology of Bacteria treated with Colicin.—Dr. Jan Šmarda 792

CYTOLOGY

Ozone-induced Chromosome Breakage in Human Cell Cultures.—Dr. Robert H. Fetner 793
Isolation of Synaptic Vesicles from Nerve Endings of the Rat Brain.—Prof. E. de Robertis, Dr. Georgina Rodríguez de Lores Arnaiz and Dr. Amanda Pellegrino de Iraldi 794
Adrenal Cytology of South Indian Anurans.—Dr. A. B. Lakshman 796

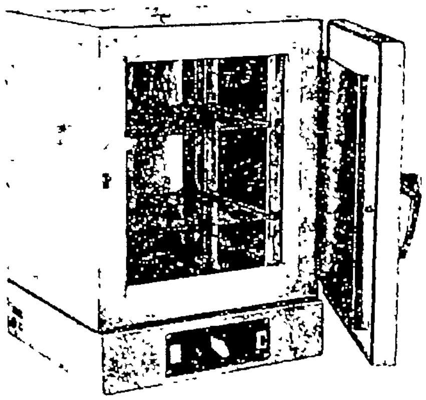
GENETICS

Slow and Fast Transferrin Variants in the Same Pedigree.—Dr. L. Beckman 796
X-ray Sensitivity of Spermatogonia and Spermatozoa in *Drosophila melanogaster*.—Karl H. Ytterborn 797

BUILDING RESEARCH

Bond of Galvanized Steel Reinforcement in Concrete.—Dr. C. E. Bird 798

LABORATORY DRYING OVENS



Hearson Ovens are designed for use up to 200° C. and available with either a mild steel or stainless-steel inner chamber. Two useful sizes are made—15″×15″×18″ high and 20″×20″×24″ high internally. The smaller model satisfies the performance requirements of BS.2648. Fan and Motor assemblies are optional extras on all models. Temperature is controlled by the hydraulic thermostat. Please send for details.

PRECISION INSTRUMENTS

Two New Refractometers

Two specialised refractometers have been built and are now offered as standard instruments in our wide range.

R.32 Employing a vee cell similar to that offered as an accessory to the Pulfrich refractometer. Intended for use with liquid samples, it has a range from 1.30 to 2.30 with an average accuracy of .0001 using conversion tables.
The principle employed is the measurement of the deviation of a collimated beam of monochromatic light through the liquid sample constrained into a prism of known angle.

R.320 For the measurement of index of a transparent liquid sample at any wavelength between 2,300 and 6,000 Å. Can be direct reading to .001 and by estimation to .0002, over the range 1.30–1.70. Photo-electric detection is employed and the instrument is open to development for recording should it be required.

DEATH OF A LABORATORY

By F. J. BOLTON

I. Even the acid-splashed benches have gone now, beside the walls
Stained blue and yellow where a flask blew up, nothing stands
But rusting iron supports. Higher, a blackboard falls
Drunken, half covering the door. In chalk of red and green, your hands
Assured and firm once drew upon its surface formulæ
As intricate as scaffolding, a patterned honeycomb extending
Unleashed across the plastered wall itself, where still I read
The molecular grouping of your own particular compound's ending.
A winter wind, focusing through the shattered panels of the window frame,
Spills on the floor mosaics of coloured glass, corks from a battered bin,
An ooze of heating oil, a snake of rubber tubing, steel tripods blacked by flame.
To-morrow week, they say, the demolition squads move in.

II. The Research Department was born three years before the War.
Then, with contracts for textile chemicals flowing in, a dream
Of twenty years before was firmly crystallized in walls
Of stone and brick and concrete. The fertile stream,
Dammed up during the lean and angry 'Thirties, burst out
In a torrent of wild purposefulness, of fierce mad
Projects and irrepressible enthusiasms, a bout
Of totally unrealizable ambitions. All these were stilled on that sad
Night when four bombs withered our fragile building to a shell.
But, miraculously, the body breathed in sleep, slowly grew strong again
And when, in the late 'Forties, the intellectual well
Was primed once more, our thoughts seemed clear and spare
As trees do after winter rain.

III. "A team is no stronger than its staunchest link" I said
Tritely "and to have a chance, an inventive mind
Is the one essential for original research." Led
Forward by this instinct, restricted by the blind
Parsimony of my directors, I searched among the very young
Outsiders, the unknowns, the untried, hoping there to find
The hundred-to-one chance, the hidden pearl, the one
Who would ask for nothing further than to work and lead
His team, younger men even than himself; above all,
A celibate, with disciplined tastes, committed and keyed
To labour for the future only, to blossom or fall
By the fruit of his own completely personal inspirations, abjuring
All luxury. Six months I took, that year before the War, and why
I chose you from the press, cajoling, luring
You from certain academic peace into this flaming trial
Of industrial warfare, I cannot rationally say; sometimes
I suppose it may have been your hand-writing, lean like yourself
And tall, your most appealing air
Of unsophisticated youth, clear laugh, rough uninhibited dress,
Your frankness, charm, the brush of flaxen hair
Falling continually across your brown eyes in the hour of stress.
But, from whatever hidden source my inspiration rose,
In this one choice of all my life, unconsciously, sheer genius shows.

IV. I remember, when the mottled structure was patched and tied together,
What dreams we harboured of relentless growth, of crystal glass
Palaces, plastic and steel, laboratory into laboratory, ever
Endlessly expanding within a telescopic future no war

Could possibly hinder. What naïve laughter we enjoyed
In planning an unorthodox shape of bench, a floor
Proof to the most violent solvents; colours soft and hard
On wall and ceiling, cerulean blue and primrose yellow.
I remember how, together, we built up our staff
Raw from college or school, some your own
Selected students, some lean and ambitious, some mellow,
At peace with the world, even at twenty, all
Enthusiastic, all disillusioned of ease, forewarned
To expect nothing but toil and trouble, to fail
Or flourish by their own silver store of talent, hard-won,
With no promise but that of fellowship, admission to a band
Of young, unconventional, non-conforming and open-minded men.
A Scotsman we had, a Yorkshireman, an Australian,
Two Londoners, an Indian, a Russian Jew, but, to us, then
With our passion for the team and not the man,
The company's and not the individual's glory, none, none was alien.

V. The sun was hanging in the sky, orange, over the Welsh mountains when you came
That night into my office. It was late, I should have been at home, instead
I stayed to read reports, to doze and watch the dying flame
Leaping and fingering through the Midland haze, the leaden
Clouds from the uncountable, the infinite number of furnace-stacks
Blocking out Nature. Half understanding, I heard you say
"I wish you'd come up into the lab. Something very strange has happened in my test-tube rack
In a set of colour tests I laid aside a week ago last Tuesday".
"Something very strange", indeed strange, stranger than we knew
Or could imagine. From that inspired observation grew
A textile industry, huge factories, a library of volumes extending still,
Miles, miles of micro-film; lectures, millions of words to fill
Vast halls and college theatres; a door
Opening on endless ocean vistas; truly a gem-like find, of the order
Of penicillin, or nylon, or polythene. A new
Original reaction, a chapter in the text-books named after you;
The joy of uncovering, in the jig-saw puzzle of life,
One perfect link, pristine and virgin-true, that no strife,
No revolution, or no Dark Age ever could undo.

VI. A glow of pleasure pulses through me as I remember how, for you,
This brought a glorious rebirth; a special Chair,
Newly created in the University; your own school of research, the air
Of academic tranquillity regained with honour kept entire;
The Royal Society; and talk now of a Nobel Prize.
But, for me, the typhoon forced its entry,
The locusts swarmed across my sky, an army of black-coated,
Bowler-hatted-brief-case-umbrella-carrying financial gentry
From Mayfair, Leeds, Liverpool and San Francisco;
The accountants, the fixers, the take-over-bidders,
The Organization men, the Yes-men, the Never-never men,
All swamping, rocking my helpless, rudderless, vessel.
The shareholders, stupefied with greed, unseeing, rid
Themselves, for a paltry two million pounds, of all their problems of development,
Selling their patent-rights, their factory and staff to a sprawling Corporation
Stitching, encapsuling each limb of every single Western nation.
And for the staff, an opening would be found "where practicable",
If your profile fitted in that continental crossword puzzle,
Yes, you might be permitted to toil on, to claim, at sixty-four, your pension rights.
But, for the original, the eccentric, the individual or the rebel
No place was vacant. To me, with grave concern, they said "Your sight
Is not as clear as once it was. Your age
Entitles you to contemplate a life of quiet

Enjoyment. Take while you can a voyage
Round the world and then retire, relying on the wealth
Accruing from your Compensation. After all, you must be passing rich.
So go now, full of achievement, and cultivate your health".

VII. As the spirit bloweth where it listeth, so can we never know
Where the germ of a conception will be born, beside a dock,
Perhaps, in Stepney, where a chemist, watching his sugar crystals go
Cascading down a conveyor while he checks his stock,
Finds fortune in an unexplained fluorescent glow
Appearing miraculously in a turning belt below.
The one, the heaven-sent, the spark-of-the-morning invention
Does not invariably strike on the benches of the strong battalions,
Along the polished corridors where the meticulous salary-scales flow,
Where the modulated pension scheme lives, breathing on the firm foundation
Of a Lombard Street bank grounded on hardest mountain rock.
It came to you here, under-paid, despised, unknown,
To you here, hidden in an industrial slum, here,
Whom the university professors, the leaders of industry, grown
To magnificence on fat years of boom, had for all those years
Written off their trim maps of what had been and what was yet to come.

VIII. And yet, this invention was not a single isolated deed
Growing within your mind from barren soil, was not
An individualistic exercise, fruit of long contemplation, seed
Of withdrawal. Born, in hard truth, from the most intense, most hot
Controversy, discussions, winding, weaving between us all
For months and years; from hard reading and thinking, toil
And sweat; from fellowship, from friendships that no call
Of personal ambition nor jealousy nor pride nor pique could spoil
In all those months and years; and these bonds live,
The binding mortar of facing a hopeless task together,
Fighting great odds together, opposing those who despised
Us and our folly, those who felt fear, who wondered whether
Such flights were not beyond our tiny power, strive as we might;
Still, to this day, the love and togetherness survive.

IX. This building, deserted now, lost, of no interest, of no financial value,
Has history in its veins; back, back, two hundred years ago
At the beginning of the Industrial Age, when men first knew
Ways to make vitriol or caustic lye, a slow
And dangerous business, breaking men's lives, grew
Here. Blinded, with lungs corroded by chlorine, blood toxic with lead,
Men still built on, rank pressing on rank until
At last, when we took over, the structure had become a rambling shed,
Used the last sixty years for storing carboys, an overspill
For empty drums, enamel pans and parts of copper still-heads.

X. Here the natural order is reversed, steel and concrete grow
To fields and woods; where once the Bunsen burners glowed
Scattering the sunlight, primroses and daffodils
Will greet the eye, gilding the parkland
That is to lie here. Where science's sharp chill
Winds once blew through corridor and dark-room, pails of sand
Are changed to rose-tubs, tracery of stainless steel and glass
Tubes, condensers and columns to tracery of leaves
And beech-wood, twigs and buds; to soft grasses
Silvered under the light the May moon weaves.
And, as the prophet or the painter or the poet stains
For ever his native ground, leaving, even on the evanescent rain,
An invisible mirror-image that no doom, no war can drain
To nothingness; so here, will your discovery clear
And crystal bright, linger for ever in the autumn air.

SCIENCE AS A PROFESSION

EXCEPT in Roy Lewis and Angus Maude's *Professional People* the position and problems of the professions in the society of to-day have received little discussion since Sir Alexander Carr-Saunders and P. A. Wilson published their major study a generation ago. The recent Cantor lectures of the Royal Society of Arts scarcely fill this gap, nor indeed do they attempt to do so, for they are ostensibly limited to the influence of the professions on economic life. Mr. A. H. Ensor, in the third lecture, discussing the commercial professions, gives banking much more extended treatment than it received from either Lewis and Maude or from Carr-Saunders and Wilson, though rather at the expense of accountancy, and his lecture has little relevance to the professional problems of which the scientist or technologist in general is often acutely aware to-day.

Mr. A. M. Holbein, in dealing with the industrial and technological professions, is much more fundamental in his approach, particularly in dealing with engineering, where he traces briefly the development of the professions and defines a professional engineer in terms approved by the Commonwealth Engineering Conference in 1954 and earlier at a conference of representatives from the engineering societies of Western Europe and the United States. The definition refers to competence in virtue of fundamental education and training to apply the scientific method of outlook to the analysis and solution of engineering problems and the emphasis is on technical competence, though admittedly not narrowly conceived. It does not refer to standards of professional qualifications or conduct, nor to the idea that professional status is essentially an implied contract to serve society over and beyond all specific duty to client or employer in consideration of the privileges and protection society extends to the profession.

The weakness of the definition appears more particularly when Mr. Holbein attempts to indicate the range and scope of what he terms the industrial and technological professions, though the difficulty may well arise out of the particular approach he adopts. He does not, as with engineering, in which incidentally he makes the sound comment in passing that the influence of the engineering profession on economic and public life might have been more profound had the great engineering institutions been less rigid in their attitude to one another, trace the development of particular occupations up to the point at which a reasoned argument could be developed for professional status. On the contrary, he appears to assume that almost any industrial grouping will afford specific professional groupings, and the result is a hotchpotch of 'professional' occupations which confuses the lines of those which are firmly and clearly based on such a discipline as that of chemistry or physics. Apart from the engineer, Mr. Holbein scarcely displays one profession that would have been admitted unchallenged in Carr-Saunders and Wilson's survey, and although admittedly the chemist and the physicist are covered by Sir Patrick Linstead's lecture the picture Mr. Holbein gives is in consequence unconvincing and perhaps unfortunate.

Nor is this all. While he rightly distinguishes between the professional man or woman as an individual and the professional institutions, particularly in considering the professional influence on economic life, it might have been wiser to take the influence of the institution first. In 1933 Sir Alexander Carr-Saunders and Mr. P. A. Wilson wrote: "If men found in vocational associations their permanent anchorage and shelter, they could move out from those secure positions to shape organizations into instruments for the fulfilment of their purposes. . . . So long as men are unable effectively to shape the instruments through which they serve, they will feel helpless; and if they feel helpless in regard to matters affecting their own vocation and its daily exercise, they will feel still more helpless in regard to matters beyond their immediate ken".

The passage of thirty years has testified to the wisdom and prescience of those words. The function of professional institutions in the economic life of to-day has steadily increased in importance as the scale of professional and economic organization has grown and the complexity of professional relations has multiplied. More than ever to-day professional men need their permanent anchorage and shelter; even more important is it that such anchorage and shelter should be seen to depend clearly on professional standards and conduct. The professional man may have to look first to his professional institution in which he qualified, but the practice of his profession in a particular way may involve other professional considerations—to many scientists teaching presents a pertinent example.

That may be one reason for deploring the excessive multiplication of professional distinctions; it is a weighty reason for emphasizing the contractual aspect of professional life rather than technical qualification, its social at least as much as its technical responsibility. It is over these that Mr. Holbein seems to pass too lightly, though he clearly recognizes them, and refers to the problems of professional education involved, including that of training the supporting echelons of technicians and craftsmen. He does not advocate any lowering of standards, though he suggests that the boundaries of the engineering institutions in Britain should be interpreted more liberally, and he just touches on the difficult problem of the place of the professional man in government.

Mr. Holbein scarcely does more than indicate the existence of this problem. On the mechanism of advice he seems to look to a super-organization of professional bodies, competent to present the collective view of the professions, and on the participation of the individual technologist he only refers to the bearing of the general element in his education. The technical or scientific element in any problem, however, is specific, not general, and the mechanism of advice must accordingly provide for the specific.

Much more fundamental thinking is required on these issues which Carr-Saunders and Wilson explicitly raised but they lie rather outside the influence of the professions on economic life, though, so far as the individual is concerned, the very growth and multiplication of the professions enhances the importance of the professional ideal, independent of its particular technical or occupational characteristics. It is that ideal with its sense of public responsibility and conception of personal service that will inspire the kind of service required and counteract the aberrations that have sometimes injured the public interest.

On the scale of the professional influence, Mr. Holbein puts the number of qualified engineers in industry and public corporations in 1960 as more than 64,000. To this must be added those in independent practice. In the meantime, it should be noted that of 66,000 on the medical register, some 47,000 are employed in the National Health Service. Sir Patrick Linstead, quoting the last report on the demand for scientific manpower, gives a total of 72,000 scientists and more than 100,000 technologists in 1959, a total as large as that of men in the Church, the Bar, Medicine, the administrative grade of the Civil Service and officers in the Fighting Services put together. Even excluding technologists, there are now more professional scientists at work in Britain than doctors or officers in the Armed Services, and it should also be remembered that the Administrative Class of the Civil Service and the Armed Services employ a small but increasing number of those qualified also as professional scientists. Furthermore, as Sir Patrick Linstead notes, the practice of science is now among the largest of the professions and also one that has grown up almost entirely during the past half-century.

Sir Patrick recognizes that the scientific professions, though so numerous, do not constitute a sphere comparable to the Bar or medicine, in which practice is restricted by law, nor does he pursue this issue of registration or even discuss the characteristics of a profession. Indeed, much as Mr. Holbein, he is concerned with the effect of science, rather than of the professions as such, on economic life. His lecture has more in common with Heath and Hetherington, *Industrial Research and Development in the United Kingdom*, or with the excellent monograph published by the Royal Institute of Chemistry, *What Industry Owes to Chemical Science*, than with Carr-Saunders and Wilson's work or that of Lewis and Maude.

This is disappointing for, competent as, of course, is Sir Patrick's discussion of the influence of the scientist, or of science, on the protection and maintenance of life, on production, on communication and computation, on education, or on innovation, it scarcely distinguishes the real professional issues, and these are important. The community should, indeed, appreciate the conditions of former innovation and invention and be ready to ensure the existence of such conditions. That, however, is rather an aspect of the influence of society on the inventor or the professional man whereas what one might have expected in a series of Cantor Lectures under this general title is consideration of the influence on the economic life of the country of the professional, rather than the scientific and technical, aspect of the life of this considerable body of trained men and women, the significance of their professional outlook and standards of conduct, the character of their professional institutions, and their appropriateness for serving professional and public needs to-day, and perhaps a glance at the complex welter of problems which arise out of the interrelations of professional institutions themselves, questions of qualification and training, and of relations between professional bodies themselves and those which meet the needs of the supporting technicians and craftsmen on whose services the professional scientist and technologist depends in increasing measure if his services are to be used with full efficiency.

Whatever their intrinsic merits, these Cantor Lectures disappoint the hopes justifiably raised by their title. To the discussion of the place of the professions in the modern world they contribute little, if anything. The large issues which have grown in importance and complexity since Carr-Saunders and Wilson wrote are ignored; others which were only emerging when Lewis and Maude wrote ten years ago are no less passed by; even the significant fact that probably at least 10 per cent of the population is now a professional worker passes without comment. Nor is the observation that already in 1952 the influence of the professions was possibly waning pursued nor are the real dangers to professional standards in some educational developments and the expansion of state employment examined critically.

Yet within the sphere of the professions and their influence, and, conversely, of the influence of society on them, are poised major problems of our day: the vital issues of power and influence, of the relation of policy to knowledge; of professional skill and wisdom in the formation and execution of public policy; of professional education and technical training, quantitatively as well as qualitatively; of the safeguarding of public standards in a score of fields, as well as questions of professional conduct and responsibility in varied and changing circumstances. Is it too much to hope that recognition of an opportunity missed may inspire the Royal Society of Arts or one or more of our great professional institutions to initiate the public discussion of some or more of these issues, starting where Carr-Saunders and Wilson or Lewis and Maude left off, and displaying the immense contribution which the professional idea, faithfully and imaginatively served, can bring to the solution of some of the most urgent problems of our day ? For if the professional institutions do not themselves meet the new challenge not simply to professional competence and standards, to professional integrity and independence and the spirit of public service, if they do not face the complex issues of administration that are involved in the relation of professional man and client in the context of nationalization and concentration in many forms, the issue of leadership is liable to go by default.

COMPARISON OF EDUCATION AND EMPLOYMENT IN THE U.S.S.R. AND THE UNITED STATES

Education and Professional Employment in the U.S.S.R.

By Nicholas de Witt. (Prepared for the National Science Foundation by the Office of Scientific Personnel, National Academy of Sciences—National Research Council.) Pp. xxxix + 856. (Washington, D.C.: National Science Foundation, 1961. Available from U.S. Government Printing Office.) 5.50 dollars.

THIS exhaustive study is much more than an enlarged and revised edition of the author's previous book, *Soviet Professional Manpower* (1955). Like its predecessor, this formidable survey is based on a tremendous amount of data derived from Soviet publications, carefully assembled, processed, tabulated, analysed, cross-checked and supplemented by travellers' reports and comparisons with the training and employment of professionals in the United States. Numerous tables, charts and graphs illustrate the organization of general and vocational training and the employment of specialists in the various fields of the national economy. The voluminous appendixes contain a great wealth of statistical data on enrolment, graduations, rates of failure and attrition, numbers and types of schools and specialized institutes, percentages of Party members among university and other staffs, of women and members of national minorities in different occupations as well as lists of school text-books, subjects taught, analyses of school and university time-tables, comparisons of medical and engineering curricula in the U.S.S.R. and United States and estimates of respective standards of attainment.

The far-reaching educational reform of 1958, which aims at introducing productive labour into secondary schools and favours the 'sandwich course' at the expense of full-time higher education, is fully discussed. Mr. de Witt argues that it was brought about by the unfavourable demographic trends and the changing labour requirements of the Seven-Year Plan. The demographic trends are the result of Soviet losses in the Second World War, which Mr. de Witt estimates at forty millions and which are known to have depleted the rural even more than the urban population. The number of school-children in the four junior grades fell from more than twenty millions in 1939 to twelve millions in 1953 and was still well below the pre-war figure in 1959. In other words, and bearing in mind the overall deficit of 21 million males, the number of 18-year olds joining the Soviet labour force in the 1960's can just about cover losses due to death and retirement; the expansion of the labour force envisaged by the Seven-Year Plan can be achieved only by employing more women and teenagers in the younger groups. The latter are being drawn into the productive process, on a full- or part-time basis, by the implementation of the new Education Act. Furthermore, the condition of two years spent in employment now required of most university entrants will help spread the full impact of juvenile labour shortage over the lean years. Many young people will probably remain in their jobs, since wages are more remunerative than students' grants, and provide skilled manual labour which seems to be particularly needed. The road to higher education remains, however, open by way of extension-correspondence courses, which in 1960–61 catered already for 1·2 million students, that is, more than half the student population. These courses have been hitherto a cheap and unsatisfactory substitute for full-time education, though they made possible the post-war re-training of teachers on a large scale. However, improving teaching techniques and radio and television facilities may eventually bring knowledge on a mass scale to scattered out-of-the-way townships and remote collective farms.

The chapter on advanced degrees and scientific research attempts no survey of Soviet science but provides much information on the personnel, remuneration and organizational set-up of higher education and research institutions. The loosely integrated research activities of the All-Union and republican academies of sciences, establishments of higher education and industrial research institutes (now under local national economic councils) are to be streamlined. On April 10, 1961, a Committee for the Co-ordination of Research and Development was set up under a deputy chairman of the Council of Ministers; it includes the President of the U.S.S.R. Academy of Sciences and the chairmen of several State committees (for automation, chemistry, inventions and discoveries, aviation engineering, armament engineering, radio-electronics, atomic energy, shipbuilding, etc.). Basic scientific research will be carried out by the Academy of Sciences while research in the applied sciences will be carried out in other research institutions.

A detailed survey of the employment of professionals and semi-professionals reflects the bureaucratic structure of Soviet society. Despite the vast numbers of graduates trained, particularly in recent years, many top managers in industry and trading organizations are still people without formal qualifications. Altogether, the output of graduates in the United States has been considerably greater in the past three decades than in the U.S.S.R. (6 millions and 4 millions respectively between 1928 and 1959), but 1·8 as many engineers have been trained in the U.S.S.R. as the United States, 2·4 as many specialists in agriculture and 2·4 as many physicians. On the other hand, in the field of social sciences, humanities and liberal arts the number of Soviet graduates is but a fraction of the figure for the United States. Both countries employ a similar percentage of their graduates in industry, transport and construction and also in Government administration, but whereas 21 per cent of the graduate force in the United States is in trade and distribution, only 1·1 per cent of their counterparts in the U.S.S.R. are in these occupations; however, the U.S.S.R. employs 43 per cent of its graduates in the field of education and the United States only 21 per cent.

The factual information contained in the book under review is quite remarkable, but the author has not and could not include in his survey the 'imponderables' that constitute a child's cultural environment. Therefore, the conclusion of his postscript implying that the U.S.S.R. trains competent but narrow-minded specialists while the system in the United States produces men and women with a broad general education fails to take into account the impact of the cultural heritage transmitted, for example, through leisure reading; in the U.S.S.R. it includes Russian and foreign classics selling in millions of copies.

E. Koutaissoff

LAND USE IN GHANA

Agriculture and Land Use in Ghana

Edited by J. Brian Wills. Pp. xviii + 504 + 59 plates. (London : Oxford University Press, 1962. Published for the Ghana Ministry of Food and Agriculture.) 63*s*. net.

THIS book is a collection of papers from 26 different contributors, the majority of whom no longer work in Ghana. These papers have been written over a period of nine years so that some of the earlier ones have had to be revised. To publish at all during a time when staff in the departments concerned was involved in the hand-over from European to African is an achievement in itself.

The book is divided into two parts, the first part dealing with the factors which influence agriculture and land use and the second part with crop husbandry, animal husbandry and forestry. In the first part there are papers on climate, geology, soils, vegetation, water supplies, flora and fauna, communications and land tenure, ending with a description of the pattern of land use in Ghana. The papers differ in length and approach. Weather and climate, soils, soil fertility and land tenure receive particularly detailed treatment, while soil erosion and conservation, mammalian fauna and communications are dealt with more briefly. Half the second part is devoted to cocoa, reflecting the importance of this crop in Ghana and the existence of the West African Cacao Research Institute staffed by people accustomed to writing scientific papers. Cocoa disease receives more attention than cocoa cultivation, reflecting the efforts made in maintaining the cocoa yield against damage by virus diseases and by capsids. A footnote to p. 252 states that the annual production of cocoa reached a new maximum of 316,000 tons in 1959–60, too late for a paper on the factors which brought about this record and a fitting conclusion to the section on cocoa. The other half of the second part deals with crops other than cocoa and with the applied aspects of forestry, tsetse flies, animal husbandry and crop storage. Other crops occupy only 40 pages and there is a lot more that could have been recorded here. Much is buried in files and some more has not been written before an officer left the country. The lime industry in the Central Region and the plant breeding work on annual crops are examples of topics which might have received more attention, but the editor may have had compilation difficulties.

The Minister of Food and Agriculture (February 1960) commissioned the book for officials, teachers, lecturers and research workers. They will find it a valuable work of reference with good diagrams, numerous tables of data, clear maps, excellent bibliographies and index. The classified bibliography is notably comprehensive. However, the editor admits that gaps exist and a fair notice must say what they are. The book deals almost entirely with environmental factors affecting land use. There are only two short papers on the human factor—the Ghanaian farmer. Agricultural surveys are included in the bibliography but they are not brought together in one paper describing how the farmer deals with his environment. Techniques of extension work are scarcely mentioned and little is said about the impact on the farmer of such new methods as mechanization, chemical control of pests and diseases, use of fertilizers and new crop varieties. Marketing likewise appears in the bibliography, but scarcely at all in the text. Education connected with agriculture and land use is omitted entirely. It is perhaps no longer possible to describe the whole field of land use in one book and this book is not a small one. It brings together in one volume a great amount of useful reference material which might otherwise have been dispersed and hard to find.

B. J. Silk

THE STRUCTURES OF SOLIDS

Structure Reports for 1954

Vol. 18. Edited by A. J. C. Wilson, W. B. Pearson, J. M. Bijvoet and J. Donohue. Pp. viii + 845. (Utrecht: M.V. A. Oosthoek's Uitgevers Mij, 1961. Published for the International Union of Crystallography.) 120 Dutch fl.; 240*s*.; 33.50 dollars.

THE International Union of Crystallography is a small Union, but it is extremely lively. Among its activities it has a very successful and useful publication policy, laid down at the time of its formation in 1946 and carried through by relatively few editors and their colleagues on editorial commissions. All of them are actively working in the field of crystallography. Its publications cater not only for the needs of research workers in structural crystallography but also for many of those of their colleagues in chemistry, physics and other major disciplines. There is the monthly periodical, *Acta Crystallographica*, which contains original papers mostly in English, but some also in French, German or Russian. There are the three volumes of the *International Tables for X-ray Crystallography* (the third of which will appear this summer) and there are also Volumes 8–18 of the *Structure Reports*, successors to the seven volumes of *Strukturberichte* (1927–39).

Year by year these *Reports* present an ordered account of material of structural interest extracted from original papers published in a wide variety of journals, including, to give some of the more exotic examples, the *Berichte Deutsche Keramische Gesellschaft*, the *Ukraïnskiĭ Khimicheskiĭ Zhurnal* and the *Travaux de Société Pharmacie de Montpellier*. As stated in the introduction, these are not abstracts in the ordinary sense, since occasionally the *Report* may be longer than the paper itself, the "abstractor" having added comments or an additional table derived from the data actually given by the author. Editorial matter thus added is distinguished by being enclosed in square brackets. Other quite long papers are described in a single line, not because they are not interesting, but because their main interest lies outside the field of structural crystallography.

One of the sensations felt on first seeing this volume is that of astonishment that within one year (for nearly all the reports in Volume 18 refer to the year 1954) so much new material should be available. Results on more than 1,900 substances by as many authors are presented here. The metals and alloys appear in alphabetical order of names, aluminium to aluminium zirconium, antimony to antimony tellurium uranium and antimony tin, and so on to more than four pages (illustrated by six diagrams) on zirconium and the thermal expansions of its two crystalline forms, as measured by X-ray diffraction. This section occupies 332 pages and is really one complete book, invaluable especially to metallurgists and engineers.

The two following sections, on inorganic and organic compounds, are also volumes in themselves. The classification is of course no longer alphabetical and the arrangement by structure types used in the earliest volumes is no longer possible, but the order followed, which is roughly chemical, is explained, and there are excellent subject-, formula- and author-indexes, including a 'duplicate' formula-index of carbon compounds only. The subject-index includes not only names of substances but also references to properties, such as entropy, epitaxy, expansion, ferrimagnetism, hydrogen bonds; to methods such as electron diffraction and microscopy, neutron diffraction and irradiation, low-angle scattering, microwave spectra; and many references to reviews. It seems strange not to find any mention in the subject-index of interatomic distances, atomic co-ordinates or space groups; but these are in fact to be found for every substance for which they have been measured in the year under review, after the name, formula and unit cell dimensions. A few curious index entries such as Aberdeenshire and U.S.S.R. seem to indicate an excess of zeal somewhere; and one could have wished also for more of the excellent diagrams that illustrate the book and for some method of numbering that did not call most of them Fig. 1.

It is perhaps too much to ask of the editors and abstractors, who are nobly doing this in their spare time, that the present gap of seven years between the year under review and the year of publication should be narrowed. But in spite of the gap, this volume and its predecessors can be most highly recommended as works of reference for all branches of science and technology that deal with solids and their properties.

KATHLEEN LONSDALE

BIOLOGY AND CANCER

Radiation Biology and Cancer

A Collection of papers presented at the Twelfth Annual Symposium on Fundamental Cancer Research, 1958. Pp. vii+493. (London: Peter Owen, Ltd., 1960.) 63*s*.

Genetics and Cancer

A Collection of papers presented at the Thirteenth Annual Symposium of Fundamental Cancer Research. Pp. ix+459. (London: Peter Owen, Ltd., 1961.) 70*s*.

FOR the study of the various problems of cancer much information is required from the fields of biological research. The M. D. Anderson Hospital of the University of Texas holds annually a symposium to discuss the latest results of current research with the view of correlating them with the various aspects of cancer. The proceedings of the last two symposia have been published: the subject of the twelfth was "Radiation Biology", that of the thirteenth "Genetics in Relation to Cancer".

Fourteen papers of the former meeting were devoted to the effects of radiation on normal and malignant cells; on cells cultured *in vitro* and to the mechanism by which recovery from radiation injury may be achieved. Methods have been described which could be used to measure and compare the effects of different types of radiation by utilizing cell lines cultured *in vitro*. Three papers, read in another session, were concerned with mutagenesis and tumour viruses in relation to radiation. Ten contributors in the symposium discussed the induction of neoplasia by ultra-violet and ionizing radiations. The possibility that therapeutic radiation, particularly in childhood, may have carcinogenic effect, has been stressed by several participants. The Bertner-Foundation lecture was delivered by J. Furth (Boston) on the subject of "Radiation Neoplasia and Endocrine System"; and dealt with the tumours of the thyroid, mammary gland, adrenal and ovary.

At the symposium on "Genetics and Cancer" twenty-three papers were presented. The somatic mutation theory of cancer and the relevance of recent findings in the field of microbial genetics, for example, lysogeny, transduction, plasmagenes, etc., have been discussed in relation to neoplastic transformation of cells. One of the contributors tried to reconcile the mutation and virus theory of cancer on the basis that certain genetic elements having properties in common with viruses might be involved in the genesis of cancer. As the neoplastic cell has a changed heredity, several contributions were devoted to the genetic material, the deoxyribonucleic acid of normal and malignant cell. The possibility that various carcinogenic agents may act by altering nucleic acid synthesis or by interfering with genetic replication has been discussed.

The results of extensive investigations of chromosome behaviour in various experimental tumours and tumour cell strains have been surveyed in great detail. These investigations show that chromosome number and structure in malignant cells very frequently deviate from those in normal cells and that the cell population of experimental tumours is highly heterogeneous. The development of drug resistance in some tumours may have been favoured by such a heterogeneity. Four contributors to the symposium dealt with genetic studies of human cancers. The results of statistical analysis of close relatives of patients with cancer of the breast and stomach indicate that susceptibility to these cancers is inherited in certain families and that repeated child-bearing reduces the risk of breast cancer. The value of twin studies and pedigree analysis has been discussed by one of the contributors. The Bertner-Foundation lecture dealt with the importance of host–virus relationship in determining the final expression of a particular disease; it was delivered by R. E. Shope (New York).

The brief survey of the contents of the two volumes shows that the meetings brought together experts in the field of physics, biochemistry, genetics, cytology, microbiology, medicine, statistics, etc.; it can be expected therefore that many readers of the papers presented at these symposia may find the subjects which have been discussed are too specialized and are only indirectly related to cancer. In my own opinion, however, the aim of the organizers to acquaint workers in cancer with recent findings of scientific research, which may eventually have a bearing on the problem of malignant disease, has been achieved.

P. C. KOLLER

THE IMPERIAL STANDARD POUND AND ITS PARLIAMENTARY COPIES IN TERMS OF THE INTERNATIONAL KILOGRAMME

By P. H. BIGG

National Physical Laboratory, Teddington

Introduction

THE Weights and Measures Act, 1878, adopted as the imperial standard of weight the weight *in vacuo* of a certain platinum–iridium cylinder marked P.S. 1844 1 lb. This cylinder had been provided following the destruction of the troy standard by the fire in the Houses of Parliament in 1834. The Act required that three parliamentary copies, constructed at the same time, should be compared once in every ten years with each other and once in every twenty years with the imperial standard. A fourth copy, immured in the Palace of Westminster, was immune from this requirement. A fifth, platinum–iridium, copy was legalized in 1886.

On the other hand, the use of metric weights was legalized by the Weights and Measures (Metric System) Act, 1897. The basis of reference in the metric system is the British national copy of the kilogramme, No. 18. This standard is one of a series of standard masses, established in 1889 and held by signatories to the Metric Convention, which are copies of the International Prototype Kilogramme. The prototype is in the custody of the Bureau International des Poids et Mesures at Sèvres, near Paris, and is the ultimate reference standard.

Legally, therefore, in Great Britain there are two independent systems of mass, based on the pound and the kilogramme respectively, a situation which in these days of increasingly precise measurement is illogical. The family of kilogrammes is more modern and much more extensive than that of the pounds, and, moreover, it is made of better material, namely, 10 per cent iridio–platinum. The stability is excellent; only a small minority of the copies has exhibited changes exceeding 0·02 mg since 1889. The international prototype was included in comparisons made in 1939 and 1946 and its high stability in relation to other members of the family was closely established. Consequently for science and technology the pound was re-defined in 1959 as equal to a definite proportion of the kilogramme, namely, 0·453 592 37 kg, and for trade this same quantity has been incorporated in Bills placed before Parliament, though so far insufficient parliamentary time has been available for their full discussion. Nevertheless, it has always been important to know the precise relationship between the pound and the kilogramme, and in consequence the two have been compared on a number of occasions. Recently, in connexion with the proposal to re-define the imperial pound it became desirable to establish the current experimental relationship and this work was accordingly undertaken at the National Physical Laboratory. A detailed report is being published elsewhere but it is thought that the present more general report will be of interest.

Comparisons of Pounds and Kilogramme 18

As one kilogramme is rather more than two pounds it was convenient to compare the kilogramme 18 with the imperial pound and its four copies taken in pairs. Since a knowledge of the values of the parliamentary copies as well as of the imperial standard was of interest, the pounds were taken in all ten possible pairs. The difference between 1 kilogramme and 2 pounds being 92·815 g (to the nearest mg) it was most economical of weights to place 100·015 g on the balance pan with the pounds and 7·2 g on the pan with the kilogramme, the total number of makeweights thus being limited to six, apart from those of very small denomination which were necessary to secure the closest possible equality of the loads compared.

The National Physical Laboratory precision balance[1], capable of discrimination to 1 μg (0·001 mg) in the comparison of kilogrammes, was used for the work, and it was found on assessing the consistency of the results of the various weighings that the standard deviation of an observed result (5 degrees of freedom) was 2·0 μg. Having regard to the fact that this variation included contributions due to errors of the small makeweights and the buoyancy allowances, as well as the balance errors, the standard deviation is remarkably small.

In order to deduce from the weighings the values of the pounds it is necessary to apply very accurate values for the various makeweights. The main makeweights were taken from a 500-g set (*PI* grammes) of platinum–iridium weights belonging to the Board of Trade which had been standardized for the work in terms of kilogramme 18. The standard deviation of the values of these weights varied from 0·9 μg for the 100-g weight to 0·3 μg for the 0·005-g weight. Various smaller weights, of aluminium and eureka alloy, were known with a standard deviation within 0·4 μg on the first occasion of standardization and 0·1 μg on the second, when an Oertling deci-micro quartz-fibre torsion balance was used.

Before the kilogramme/pound comparisons took place, the standard of reference, the national kilogramme 18, was carefully steamed in accordance with the internationally accepted process of cleaning described as 'lavage'. Before and after steaming it was compared with two platinum standards, kilogramme *E* and the headweights 500, 200*A*, 200*B*, 100 of *PI* grammes, and was found to have lost 14 μg due to the steaming, presumably due to the loss of an invisible surface film. After the kilogramme/pound comparisons, kilogramme 18 was sent to the Bureau International des Poids et Mesures (BIPM), where it was compared with the prototype kilogrammes 9, 25 and 31 belonging to the Bureau.

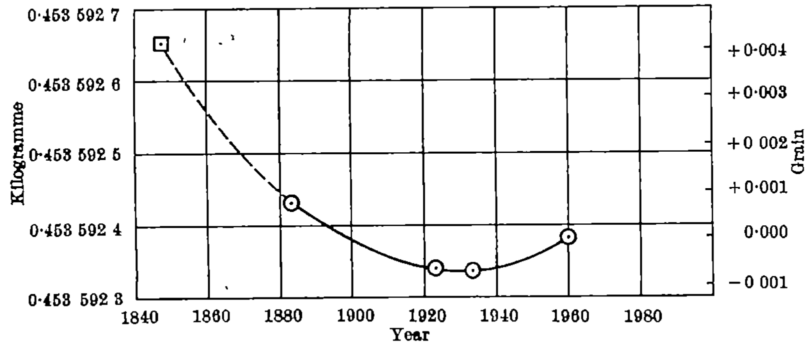

Fig. 1. Values of the imperial standard pound in kilogrammes

On return from the Bureau it was again compared with kilogrammes *E* and *PI* and the results are given in Table 1.

Table 1. Results of Comparisons of Kilogrammes (unit 1 μgm.)

	E–PI 41 900 +	*18–PI* 44 000 +	*18–E* 2 100 +	Residual
Before comparisons with pounds	29·8	107·9	77·8	− 0·8
After comparisons with pounds and re-verification at BIPM	25·8	109·7	(93 6)	(+ 9 7)

Table 2. Values of Kilogramme 18

Year	Mass	Surface condition
1889	1 kg + 70 μg	After steaming
1924	1 kg + 51 μg	No steaming*
1933	1 kg + 58 μg	No steaming
1948	1 kg + 71 μg	After steaming†
1961	1 kg + 59 μg	After steaming

* Kilogramme 18 had been cleaned in January 1923 with a mixture of ether, alcohol and ammonia.

† On this occasion the reference standards of the Bureau had been subjected to steaming for the first time since their establishment.

Table 3. Values of the Pound Standards, 1960

Pound	Value (kg)	Error of copy pound in terms of the imperial standard (grain)
Imperial standard	0·453 592 383	
Copy No. 1	0·453 592 599	+ 0·003 33
Copy No. 2	0·453 592 452	+ 0·001 06
Copy No. 3	0 453 592 297	− 0 001 33
Copy No. 5	0·453 592 138	− 0 003 79

During the final comparison of the second cycle, that between 18 and *E*, foreign matter was observed on one of the balance pans and one-half of the weighing was accordingly repeated; the closing error was nevertheless relatively poor. The other results, however, serve to indicate that during the vital weighings kilogramme 18 remained highly stable and the value certified by the BIPM could with confidence be applied to the kilogramme/pound comparisons.

The certified value for kilogramme 18 is given in Table 2 together with the values previously certified.

It may be noted that the standard deviation of the five values is 9 μg and that of the three values associated with lavage is 7 μg. Further, it was stated by the Bureau, presumably on the grounds of its general experience of such weighings, that the kilogramme cannot be said with certainty to have changed since 1948. The standard deviation 7 μg was adopted by the National Physical Laboratory for association with the 1961 value when assessing the results of the kilogramme/pound comparisons.

Results

Calculation of the values of the pounds in kilogrammes by the method of least squares, using kilogramme 18 = 1 kg + 59 μg, led to the results given in Table 3. The standard deviation of each value, comprising contributions from kilogramme 18 (5·0 μg), the weighings (1·1 μg) and the makeweights (1·4 μg) was 5·3 μg and the uncertainty of the values in Table 3 is accordingly 16 μg (corresponding to 0·000 25 grain) on a 99 per cent confidence basis.

Discussion

The values found for the imperial pound in the present and in previous determinations are plotted in Fig. 1.

It will be seen that all the values lie in a smooth curve and that for the first time the latest value shows an increase in comparison with immediately preceding values. The increase since the last two (closely concordant) evaluations is 42 μg or 0·0006 grain, that is, about 1 part in 11 million, a statistically significant amount. It is difficult to explain the increase except in terms of the accumulation of invisible film on the surface of the pound which is resistant to removal by light brushing, the wear which may be presumed to have occurred being relatively slight in effect. It may be noted that the pounds were submitted to liquid cleaning in 1922, but more recently this has seemed inappropriate because several of them, including the imperial standard, are not integral but had plugs of platinum incorporated in their flanks when they were originally made, presumably to remedy local faults. The weights were conditioned for the weighings merely by dusting with a camel-hair brush.

The differences between the imperial standard and the copy pounds in the present and previous determinations are shown in Fig. 2. The differences for 1960 are estimated to be accurate to approximately 0·000 08 grain (5 μg) on a 99 per cent confidence basis. The curve for Copy No. 1 is exceptionally

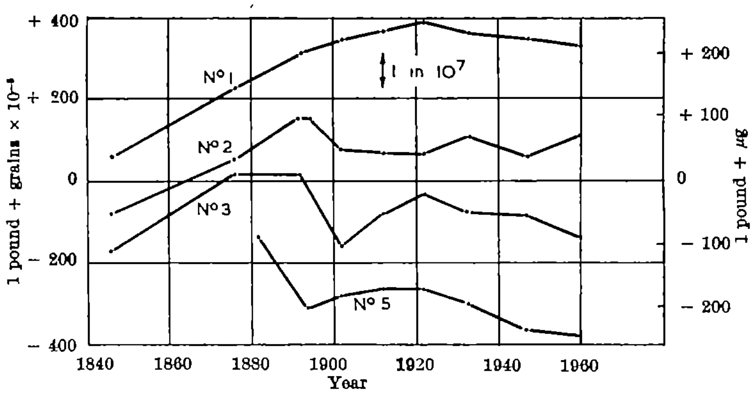

Fig. 2. Values of the parliamentary copies of the pounds

smooth during the whole period of its life, indicating that neither it nor the imperial standard has exhibited spasmodic fluctuations. Since 1922 all the standards with the exception of No. 2 have shown smooth progressions. Copy No. 2 was the subject of difficulty during the 1947 decennial comparisons when definite evidence of a change during the comparisons, amounting to 14 × 10^{-5} grain, was found. The reduced rate of change of copy No. 5 during 1947–60 as compared with 1932–47 has been due to its being used less during the later period. Considering the mean values of the copies for the several years we find the values which are set out in Fig. 3. Whether copy No. 2 is included or not the tendency exists for the copies to have lost relative to the imperial standard since 1922, or alternatively for the standard to have gained relative to the copies. Bearing in mind that by comparison with the kilogramme 18 the value of the imperial standard was almost the same in 1922 and 1932, we compare below the change since that decade as indicated by the pound/kilogramme comparisons and by the pound/copy pound comparisons. The results are as follow:

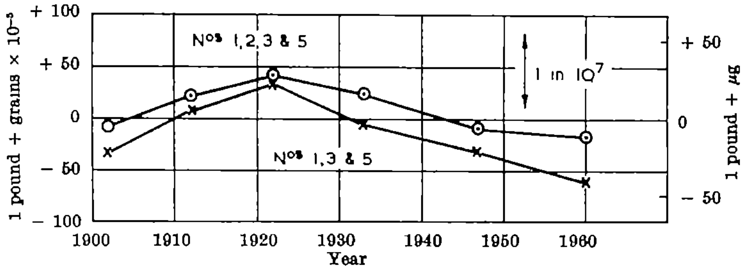

Fig. 3. Means of values of certain parliamentary copies of the pounds

Gain of imperial standard pound according to pound/kilogramme comparisons	42 μg
Gain of imperial standard pound relative to Copies 1, 2, 3 and 5	33 μg
Gain of imperial standard pound relative to Copies 1, 3 and 5	49 μg

Although too much confidence must not be attached to the conclusion, because the copies have been used more than the imperial standard, it nevertheless seems that the evidence from the copies, supporting that from the pound/kilogramme comparisons, is that the imperial standard has gained mass during the past few decades by about 1 part in 10 million.

It may be noted that the latest value of the pound, 0·453 592 383 kg, is very close indeed to the value adopted in July 1959 for science and technology[2] by the national standards laboratories in the English-speaking countries, namely, 0·453 592 37 kg. This closeness of agreement is fortunate, but purely accidental. At that time the United Kingdom pound was thought to be 0·453 592 338 kgm. (1932 value) and the U.S. pound was legally defined as 0·453 592 4277 kgm. As the pound is divisible into 7,000 grains it was advisable to choose an equivalent which is readily divisible by 7, and in consultation with the United States the choice fell on 0·453 592 37 kg, this being approximately midway between the United Kingdom and United States pounds. At the time it was thought that the kilogramme/pound curve, which of recent years was horizontal, would continue so, providing evidence of a stable relationship between the two units. That the 1960 value has not fulfilled this expectation but has demonstrated a decided upward turn to the curve shows how valuable was the decision to adopt once and for all, for precise measurements in science and technology, a constant relationship between the pound and the kilogramme. It is to be hoped that parliamentary time will soon be found to legalize this relationship.

The work described here was carried out as part of the programme of the National Physical Laboratory for the maintenance of standards, and this article is published by permission of the Director. Miss D. Oxley carried out all the weighings and Mr. F. H. Burch was in immediate charge of the work. Acknowledgement is made to the Standard Weights and Measures Department of the Board of Trade for co-operation in transporting the pound standards between its normal storage places and the National Physical Laboratory.

ORGANIZATIONAL PROBLEMS OF SCIENTIFIC RESEARCH IN THE UNIVERSITIES*

By Prof. P. M. S. BLACKETT, F.R.S.

Imperial College of Science and Technology, London

WHEN an institution increases markedly in size, changes must be made in organizational methods. This is true of a government department, an industrial firm, a university and a university science department. I will mainly confine myself here to the postgraduate research and teaching in a university science department, though I shall also refer to undergraduate teaching.

Naturally I am drawing widely on my own personal experience as a university teacher and research worker, so my remarks may be unduly conditioned by my particular experiences. An even greater risk is that I may be taking too much the view of the man-at-the-top, for I have been head of a department, or rather three different departments, for just thirty years, and so have exercised great, but rather undefined, powers. I vividly recalled something which happened at the Princeton bi-centennial celebrations in 1946. That great British industrial scientist, Dr. C. K. Mees, creator of the Kodak Research Laboratories in the United States, gave a brilliant lecture on the right way to run an industrial research laboratory which was, of course, the way his laboratory was run. Then a young scientist from Mees's laboratory got up and spent half an hour telling us with great clarity what it was really like—as seen from the working researcher's point of view.

---

* Substance of an address given at the opening of the new Physics Building at King's College, Newcastle upon Tyne (University of Durham), on March 16 (see also *Nature* of April 14, p. 134).

Much of what I have to say is generally accepted doctrine, but other parts, I think, are not. Anyway, it has been useful to me to formulate my views on these important matters, so I hope it will also be to those who hear or read them.

I am very convinced of the extreme value of associating research and teaching. In fact, a large fraction of the most creative scientists of Britain are engaged in both, and it is essential to retain this. Moreover, the welcome increase of postgraduate specialized training provides a valuable part of the work of the teaching staff and one in very close and valuable relation with their researches.

Now it is clear that since before the War a numerical revolution has taken place in the production of trained scientific and engineering manpower in Britain. In 1938 the annual output was 5,000: in 1960 it was 17,000, and the present target is given as 30,000 by the early 1970's: this implies a rate of increase of 7 per cent a year over the next decade. A large part of this rapid expansion is taking place in existing university departments, which are therefore growing rapidly in size, generally at a rate of 5–10 per cent a year. Compared with 1938, an average physics, mathematics or chemistry department has nearly four times as many undergraduates and a rather greater increase of staff—thus giving a welcome improvement in the staff/student ratio. On the other hand, the number of senior posts, particularly professorships, has not increased as fast. Taking all university subjects, the ratio of professors to total staff was 1 : 5 in 1938 and only 1 : 8 to-day. In pure science the ratio is now only 1 : 9 or 10.

There cannot be much doubt that this failure of the number of senior posts to keep pace with the increase of the other staff, so reducing the chances of promotion and the exercise of individual initiative, has been a major cause of the loss of many outstanding scientists to the United States and to not a little general disgruntlement among university staffs [see also *Nature*, 193, 911, 922; 1962] I consider that it is important that the number of scientific professorial posts be increased during the next decade to about 1 in 5 of total staff, thus achieving the general university figure of 1938.

Let us consider the position in the thirty-five university departments of physics in Great Britain. In 1961 there were about 700 total academic staff and some 65 professors, giving a ratio of about 1 : 10. So to achieve the above objective, about 60 extra chairs are needed (that is, nearly a doubling) apart from the number required by the planned general expansion of the science departments by 70 per cent in the next decade. So the total number of physics chairs by the early 1970's should be more than 200. To-day, out of 35 university departments of physics in Great Britain, 17 have a single professor, 8 have two, 5 have three, 3 have four, 1 has five and 1 has nine. Taking all sciences, technology and medicine together, the number of chairs has increased from about 870 in 1958 to 975 in 1961, that is, by about 105 in 3 years or 4 per cent a year. More than a doubling of this rate of increase will be required in the next decade to compete with the planned increase of the universities as a whole and with the restoration of the former ratio of professorial to total staff.

What are the reasons for the failure of the universities to increase the number of chairs to keep pace with the expansion of the departments ? In a few cases there may have been a lack of suitable candidates: however, I very much doubt if this is an important factor except perhaps in the smaller, more remote and least well-endowed departments. Nor is it often a matter of finance: for example, the cost of upgrading a readership to a chair need only be a few hundred pounds a year. Nor does there appear to be any rigid University Grants Committee regulation against an increase of professorships.

The real reason, I think, for this serious failure is to be found mainly in the innate conservatism of universities as a whole. Of course, the universities other than Oxford and Cambridge have been influenced historically by the Continental tradition of a department with one well-paid professor and a number of badly paid juniors. In Scotland, where this tradition was strongest, I am told the creation of new chairs in some Scottish universities still requires an alteration of the statutes and the agreement of the other Scottish universities.

Fears have often been expressed that too many professors will make university senates too big and so unwieldy, and too many science professors will alter the balance of the government of a university. The first difficulty can be mitigated by suitable administrative changes and, as regards the second, it is to be remembered that to-day there are 520 arts professors to only 340 science professors. The higher professor/total staff ratio of 1 : 6 for arts compared with 1 : 9 for science, arises, I think, mainly because of the larger number of small arts departments with a professorial head but few other staff.

In the cases of a few individual professors of physics opposition to increasing their number may have been based on a reluctance to share power and prestige. More reputably, there may have been some fear of the administrative problems of the multi-professorial department. These problems exist, and I will now consider them, specifically in relation to physics. Other big experimental departments such as chemistry and engineering clearly have somewhat similar but not identical problems. But mathematics departments again have fewer problems because of the lack of experimental research.

I would like to emphasize here that my advocacy of many more professorships in no way implies that I think a professorship should be a normal promotional grade for all members of the staff. I strongly oppose this: but I do think that there will be found available men and women of outstanding gifts to fill the new posts which I think are needed over the next decade.

Consider a moderately large physics department with an average of 100 undergraduates taking honours physics in each of three years, giving an undergraduate population (not counting students from other departments) of 300. Taking the present average staff/student ratio as 1 : 7 or 8, as seems accepted as reasonable, there will be about 40 staff in the department. Accepting further that 1 in 5 of the staff is a professor, there will be 8 professors. What should be the relation of these professors to each other and what part should they play in the three main functions of the staff—undergraduate teaching, postgraduate teaching and direction of research? There are clearly several possible arrangements which can give satisfactory results.

My own preference at present is on one hand for a completely unitary undergraduate teaching organization for a single unspecialized B.Sc. degree in which every member of the staff, including professors, takes part in the teaching: and, on the other hand, for a number of research units with the maximum possible autonomy at the postgraduate-level. In general, I think that every professor, if he wants to, should direct such a unit: in our imaginary department there will then be about eight such independent research units with an average total of five academic staff each.

Experience shows that on the average such a research unit with five academic staff may require half a dozen technicians of different grades, and if successful should attract a dozen or more research students and other research workers, so giving an average total population of, say, 25. In the Department of Physics in the Imperial College of Science and Technology, where there are 11 units, the total numbers in each range from about 12 to 45.

I would like to mention here an experiment in architectural planning a large physics department which we have made at Imperial College. In order to promote the maximum internal scientific and social cohesion of these research units, the new Physics Building was designed to allow so far as possible the allocation of a compact area of the building to as many units as was architecturally possible. The academic staff, including the professor together with the technicians and research workers, of a unit are all accommodated in this area. This architectural division of the research space of the whole department into more or less defined areas, housing separated research units, has a possible disadvantage in perhaps making more difficult re-allocation of space at a later date. However, its advantages are considerable over the extreme alternative, which is to house all the heads of groups in one area of the building and to distribute their respective research laboratories more or less at random over the whole building.

In my experience to-day, the average minimum size for a research unit is just about what I have mentioned, that is, five academic staff with supporting technicians and research students. Remembering that the staff are only part-time research workers, and in view of the problems of keeping up with the literature, attending conferences, etc., it is seldom possible for a much smaller group to make an outstanding contribution to a research subject in the front line of advance. Smaller and weaker groups can easily become sub-viable: they can fall below the critical size for self-sustaining research progress. These considerations apply, of course, only to groups of normally gifted workers: special arrangements can always be made for the outstanding lone worker, a C. T. R. Wilson, a Glaser or a Mossbauer.

Such a multi-professorial department can be directed in one of three main ways: one of the professors can be permanent head of the department—this is the traditional Continental solution: one of the eight can be temporary chairman—this is often done in the United States—or some form of committee can run the department. There are advantages and disadvantages in all these methods. It must be remembered that excessive departmental democracy can be very time wasting and so impede research. The main function of the central direction in relation to the research activities of the eight units is to distribute to the units the available money for research expenses received from the university, to allocate the academic staff vacancies, and, in conjunction with the university, to fill them: and finally, to allocate each summer to the units the new research students from the main teaching department. On the other hand, I think that the heads of the research units should take almost complete responsibility for acquiring outside finance, for example, from research councils or industry, etc., and for attracting research students and visitors from other institutions at home and abroad.

I would like now to refer to university research in border-line subjects. There is no doubt that the present method of finance by the University Grants Committee, which involves basing its grant to a university mainly on the number of undergraduates, does make difficult the development of specialized and border-line fields of research. Since there are few, if any, undergraduates, there are few staff and so little research, unless large outside funds are available. On the other hand, it seems likely that the importance of, and the interest in, these ever-arising new border-line subjects is likely to increase in the future.

In my view, it is generally a mistake to attempt to found an undergraduate school, giving a specialized B.Sc., at too early a stage of a new subject, simply in order to acquire the staff to make a research school. For one thing, the best students from school will seldom enter for such unfamiliar subjects: of more importance is the new general recognition that the undergraduate teaching course should be mainly concerned with the basic sciences, with only a minor degree of specialization in the last year. Training in the vitally important, but highly specialized new subjects, comes much more efficiently in the early post-doctorate years. A convenient way of dealing with some of these new subjects is to make a group working in such a field into a unit in one of the major departments of physics, chemistry, etc. As already outlined, the academic staff of these units would all take part in the general undergraduate physics teaching, but would be free to develop, as thought fit, the postgraduate specialized training required by their subject. A great advantage of this organic relation between a highly specialized research unit and a major teaching department is that it provides a potential supply of home-grown postgraduates. For example, in our imaginary department of physics with an output of about 80 graduates a year there will usually be up to 20 who can be considered as fit for a research studentship, and so an average of 2 or 3 for each of the 8 assumed research units. In addition, a good research group will normally attract at least as many or more from other universities, particularly those overseas. In the past it has been the lack of direct and formal right of access to a major teaching department which has often made such subjects as astronomy, meteorology and geophysics into the cinderellas of our university system. Sometimes, such departments have very few British research students, so that they have to rely mainly on overseas students. It is interesting to note that, because radioastronomy in both Cambridge and Manchester did grow up as sub-departments of major departments of physics, there has been a continuous flow of first-rate British physicists into this subject.

ØKSFJORD EXPEDITION, NORTH NORWAY

TWENTY graduates and undergraduates from the University College of Swansea spent more than ten weeks during the summer of 1961 on the isolated peninsulas and islands between Skjervøy and Øksfjord, West Finnmark. A comprehensive research programme included geology, biology, ornithology and mountaineering.

Two main camps were established at Sandland and Olderfjord with smaller or temporary camps at Andsnes, Segilvik, Sor Tverfjord and Langfjord Botn (geology); at Nor Tverfjord (mountaineering and geology) and Loppa (ornithology and geology). Movement between camp sites and the geological work along shore sections was greatly facilitated by the Expedition's dinghy and outboard.

The team of six geologists completed a preliminary geological map of the triangular area from Silda Island in the north to Jøkelfjorden in the south and Andsnes in the west. Because no accurate large-scale topographical maps were available, the geology was recorded on traces overlying air photographs. The structural sequence of Eocambrian and Cambro-Silurian metasedimentary rocks west of Sandland Village is massive quartzites, often including broad amphibolitic bands, followed upwards by purple staurolite-garnet schists and a sheeted sequence of limestone and gabbro at the top. Basic dykes occur in all three units, and this part of the area has been metamorphosed to the amphibolite facies. Eastwards, the metasediments are separated from the main gabbro-garnet gneiss complex by a zone of intensive faulting passing through Sandland Valley.

Broad alternating bands, from 100 to 500 ft. thick of hypersthene gabbro and coarsely banded garnet gneiss constitute the gabbro-gneiss complex, the western margin of the huge layered Seiland Gabbro. In places the gabbro is choked with metasedimentary material and a granulitic variety of hypersthene gabbro outcropping along the sides of Langfjord includes narrow bands of quartzo-feldspathic and limestone metasediments, less than 20 ft. thick but traceable for more than a mile parallel to the foliation. This part of the area has been metamorphosed to the granulite facies. Into the gabbro-gneiss complex are intruded a coarse olivine gabbro, a periodotite-anorthosite complex, ultrabasic dykes, basic dykes and syenites.

At least three-fold systems can be distinguished in the metasediments, the two most important striking N. 20° and N. 340°. The predominant structural trend in the gabbro-gneiss complex curves gently from N. 20° in the north to N. 340° in the south. Mylonite zones, concentrated along the gabbro-garnet gneiss contacts indicate a number of thrust planes, parallel to the foliation, dipping between 60° and 30° west. East of Langfjord the dip of the foliation steepens and passes through the vertical to dip steeply east.

Much work remains to be done. This year's preliminary map must be extended eastwards to Øksfjord to join up with areas mapped by other workers. More detailed investigations of the metasediments and their structure and of the origin of the various basic and ultrabasic rocks must be completed before a comprehensive reconstruction of the geological development of the area is attempted.

Biological studies were carried out in the area of Olderfjord, Reinfjorddalen and Kanesdalen. Extensive collections of angiosperms and bryophytes were made and particular attention was paid to the variation of *Salix* species. A general botanical survey was made as a basis for further ecological studies and future work on the variability of breeding systems.

General collections were made of small mammals in order to study their parasites and of insects, the distribution of which was related to vegetation, altitude and other factors. Sea-shore collections were made with particular reference to the taxonomy of the isopod crustacean *Jaera*.

A specially designed apparatus was used for quantitative sampling of the soil fauna at some 72 different sites, involving more than 400 sample units. Apart from obtaining zoogeographical data on the distribution of arctic invertebrates the intention had been to relate detailed distributions of mites and collembola to vegetation and altitude. However, the effects of exposure and aspect were so extreme that simple relations could not be detected and a phenological reference system was used instead. The effects of solifluation patterns and related phenomena were studied and work on the identification of the soil fauna is now in progress. This has proved interesting; 50 species of mites and 25 of collembola have been identified and some of these have not been described previously.

The three ornithologists collected data on the occurrence and distribution of birds from the Sandland and Olderfjord areas and from the Island of Loppa. A short visit, in bad conditions, was made to the large auk colony on Nord Fugløy.

Some 220 birds were trapped and ringed. The largest group was of redpolls, *Carduelis*, and the detailed descriptions made at the time are now being compared with those from skins in an attempt to determine the taxonomic position of the Øksfjord Peninsula birds. One ringed redpoll has already been recovered in Russia and a fieldfare from the south of France.

A small colony of arctic tern, *Sterna macrara*, on an islet off Sandland Peninsula had an extended breeding period and 25 chicks were ringed. On the Island of Loppa a detailed survey of the bird population was made.

Geomorphological work included the mapping of morainic features around the northern and western sides of the small ice-cap. Three major retreat stages are recognized, but the final analysis is not yet complete. Detailed work on the numerous raised beaches around Langfjord and Nord Bergsfjord was initiated and will be continued during 1962.

Finally, a party of three mountaineers spent several weeks in the Nor Tverfjord area, making a number of new ridge traverses and first ascents. Svartfjell (1,218 m.), the highest mountain in Finnmark, was climbed and a number of days were spent on the dramatic gabbro ridge separating the Sandland and Sor Tverfjord valleys. Gabbro rock, abundant in the area, provides a great deal of interesting, sometimes spectacular, climbing, but semi-frozen scree and loose blocks constitute an unwelcome hazard on all but the steepest faces.

The expedition was sponsored by the University College of Swansea and generous financial assistance was received from the Royal Society, the Royal Geographical Society, the Everest Foundation, the Gilchrist Educational Trust and the C. H. Foyle Trust among many others.

P. R. Hooper

DISTRIBUTION OF ARSENIC IN NAPOLEON'S HAIR

By Dr. HAMILTON SMITH, Dr. STEN FORSHUFVUD
and Dr. ANDERS WASSÉN

Department of Forensic Medicine, University of Glasgow, and Vasagaten 33, Goteborg C, Sweden

THE illness Napoleon suffered during most of his captivity on St. Helena was actually the syndrome of chronic arsenic intoxication with intercurrent attacks of acute arsenic poisoning, as reported briefly in *Nature*[1] and discussed at length in a reassessment of the disease history by one of us (S. F.)[2]. Among the facts adduced in support of this theory was the finding that a few rather short hairs known to have been taken from Napoleon's head, presumably the day after death, showed a total arsenic content of 10·38 p.p.m., a value approximately thirteen times higher than the normal mean arsenic content of about 0·8 p.p.m. It would have been interesting to examine the distribution of the arsenic, but the sample was too small (1·72 mgm.) and we were then unable to obtain further hairs from the same source.

However, on November 6, 1961, not long after the news of Napoleon's deliberate poisoning and tragic mode of death had become public property, M. Clifford Frey, a textile manufacturer of Münchwilen, Switzerland, called at the Department of Forensic Medicine, Glasgow. He brought with him a family heirloom in the form of a small bundle of Napoleonic hairs. It was attached to a piece of paper with intricately knotted twine. We were permitted to take as many hairs as required within reason, provided the knot was not undone. Thus, although some of the brittle hairs broke when being pulled free of the knot, we were able to acquire a supply of hairs which were appreciably longer than those we had previously analysed, the longest measuring 13 cm. It could be distinctly observed that most of these hairs had been shorn off with a razor and not cut off with scissors.

The paper to which the hairs were attached was folded into a small envelope inscribed "Cheveux de l'immortel Empereur Napoléon". It was inserted in a larger envelope which, in the same characteristic handwriting, bears the names of the addressee and sender, respectively, "Monsieur Mons-Riss, St. Gall, Suisse", and "Abram Noverraz, La Violette près Lausanne, le 8^{e}, 7^{bre} 1838"; it is post-marked Lausanne, September 9, 1838. The larger envelope includes a covering letter written in the same characteristic hand and signed by J. Abram Noverraz. It states, among other things: ". . . Je me fait un plaisir aujourd'hui Monsieur Mons de vous envoyez quelques cheveux de l'Empereur Napoléon que j'ai pris sur sa tête après sa mort, c'etait le six Mai 1821".

The hairs remained in the possession of the Mons family until, according to documentary proof, it was procured by M. Clifford Frey, sen., an officer of the Swiss Army, from Mme Mons-Im-Hoff, the widow of the aforementioned Monsieur Mons's grandson.

A Swiss, M. J. Abram Noverraz, born in the neighbourhood of Vaud, was appointed to Napoleon's domestic staff in 1809 and became his valet throughout the captivity on St. Helena. After Napoleon's death he returned to Switzerland. Noverraz has the reputation of being completely reliable and absolutely faithful to his master and his memory. Napoleon died on May 5, 1821, and during the following night his entire head was shaved, with the alleged two-fold aim of providing as much hair as possible for distribution as souvenirs and of facilitating the making of a death mask. The barber on this occasion was none other than Noverraz[3].

Accordingly, it seems beyond doubt that the hairs put at the disposal of the laboratory by M. Clifford Frey came from an authentic souvenir of Napoleon.

The average daily growth of hair on the scalp is about 0·35 mm. (ref. 4). On this basis a 13-cm. hair should register a record of the exposures to appreciable amounts of arsenic for a period of a little less than a year. Hence, the longest hairs in Clifford Frey's sample should tell us whether Napoleon was exposed to significant doses of arsenic over the last year.

The hair was irradiated for 24 hr. by a flux of 10^{12} thermal neutrons/cm.^{2}/sec. in a nuclear reactor at the Atomic Energy Research Establishment, Harwell. On return from the pile the hair was fixed by means of self-adhesive tape to a piece of graph paper and then cut into 5-mm. lengths, suitable for counting by an end-window Geiger counter. The results were plotted in a graph against distance from an end of the hair.

The graph in Fig. 1 shows the distribution of activity along a hair, the distal end of which is at *A*. This was a hair that had never been cut before and the very fine end (responsible for the sudden fall in activity) was easily seen. We have estimated that the line *C* is the usual average for the hair. It is certain that the peak marked *P* is due to some trace element being present in larger amounts than normal, because its height lies more than 50 per cent above the average. Accordingly, it is evident that for a period of about 4 months Napoleon was exposed to abnormally large amounts of a substance which was transformed into a radioactive isotope by the irradiation. Other hairs gave similar graphs.

In order to ascertain whether the isotope really was arsenic-16, the arsenic content was estimated[5] in consecutive 1-cm. lengths of a 9-cm. hair, the respective values being 11·0, 7·70, 4·20, 3·79, 1·06; 4·46;

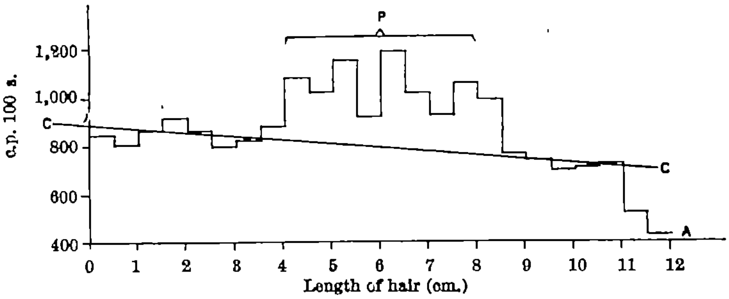

Fig. 1

5·80, 2·79 and 3·44 p.p.m. (average 4·91). Since this hair was 3 cm. shorter than that yielding the graph in Fig. 1, it lacked the older portion which was relatively free from arsenic.

The arsenic content was estimated in two pooled samples of broken hairs, the respective values being 3·75 and 3·27 p.p.m.

Estimation of arsenic by activation analysis is an extremely sensitive method. Nevertheless, the method has its limitations. When it is used on less than about 1 mgm. of ordinary hair, it yields values which tend to be obscured by the background. Accordingly, it is rather risky to apply this method to 1-cm. lengths of Napoleonic hair which weigh about one-thirtieth of a mgm. We have done so merely to provide a general picture of the distribution of arsenic in Napoleon's hair, knowing that any quantitative error will be well on the conservative side.

These distribution studies show that Napoleon was exposed to arsenic intermittently. Indeed, judging by the only hair with the distal end uncut, the periodicity of the exposures agrees remarkably well with what can be deduced about the course of Napoleon's disease from the accounts of the eye-witnesses.

The arsenic cannot have been added afterwards, by spraying, dusting or dipping, as suggested by some critics[6]. No estimate of the size of the arsenic dosage given to Napoleon can be made on the basis of our results; such very desirable information could probably be obtained after exhumation of the corpse.

In a forthcoming paper it is hoped to publish the results of similar distribution studies on hairs from other sources and other periods of Napoleon's life.

The work of one of us (H. S.) was supported by the Medical Research Council (Great Britain).

GOLDEN JUBILEE OF THE ROYAL ONTARIO MUSEUM, TORONTO

By Dr. W. E. SWINTON

Head of the Division of Life Sciences in the Museum

THE Royal Ontario Museum celebrated its golden jubilee on April 16 with a special exhibition, entitled "Search and Research", which illustrated advances in knowledge in which the Museum had participated during the past fifty years. The exhibition was opened by the Lieutenant-Governor of Ontario, the Hon. Lieut-Colonel J. Keiller MacKay. There was also a special series of lectures by distinguished scientists given in February, March and April. April 16 was the anniversary of the Museum's foundation only on paper, for it was on that date in 1912 that the Legislative Assembly of the Province of Ontario established the Museum for "(*a*) the collection and exhibition of objects of every kind calculated to illustrate the natural history of Ontario, and thereby to aid in a knowledge of what it is able to contribute to science and industry; (*b*) the collection and exhibition of objects of any kind calculated to illustrate the natural history of the world and the history of man in all ages; (*c*) such other objects as may be authorized by the Lieutenant-Governor in Council".

It may be important to repeat this enactment now, for it received no comment at the time, the event being overshadowed throughout the world, and especially in North America, by the sinking of the *Titanic*.

Within two years material was assembled, an unprepossessing building was made ready and officially opened in March 1914 by H.R.H. the Duke of Connaught, Governor-General of Canada.

Most of the materials came from the departments of the University, and right from the start emphasis was placed on art and archæology. Yet the Board had designated five museums within the whole: the Royal Ontario Museums of Archæology, Geology, Mineralogy, Palæontology and Zoology. Each had its director; its somewhat limited space; its even more limited funds; and a pride peculiarly its own which did much to ensure the rapid increase of the individual collections in size and in importance for teaching. There was an intimate connexion with the University of Toronto from the beginning, and the directors were usually the heads of the appropriate University departments.

The Geological Museum began with a fine series of Canadian silver ores, and with a remarkable collection of ornamental and building stones collected by Prof. W. A. Parks, later to be director of the Museum of Palæontology. The exhibits were, however, housed in a basement so dark and unsuited for the purpose that the public scarcely ever penetrated its murkiness. Yet the forbidding conditions do not seem to have depressed its directors. The first was Prof. A. P.

Coleman, who ministered over its unattractive cases for eight years and managed to attract many more specimens. He was succeeded by Prof. E. S. Moore, who greatly amplified the Museum's outlook. Both this Museum and its fellow of Mineralogy were allotted more equitable accommodation in 1932 when the new Museum extension, with its imposing Queen's Park frontage, was built. In 1959, in another of many reconstitutions, the Museums of Mineralogy and Geology were united as the Division of Earth Sciences, and this, under its head, Dr. V. B. Meen, has made remarkable advances both in the size of its collections and the methods of their display. Its attractive galleries are at the moment being made even more attractive with the aid of a substantial grant from the Bickell Foundation.

The Museum of Palæontology owes its history to the brief but productive professorship of Henry Alleyn Nicholson, the well-known palæontologist, who went from Edinburgh to Toronto in 1871 and who built up the nucleus of a great collection which, unfortunately, was almost wholly destroyed by a fire at the University. His example was followed fortunately by others, so that when the Royal Ontario Museum was founded there was a plenitude of materials. The first director, who had an enormous influence on the Museum, was Dr. W. A. Parks, who started off, as has been seen, with a collection of building stones, who became head of the Department of Geology in the University, and was an authority on invertebrate palæontology. He was also the progenitor of the fine collection of dinosaurs which is one of the claims to fame of the Museum to-day.

Royal Ontario Museum expeditions, especially those under the charge of Mr. Levi Sternberg, have made remarkable discoveries in Alberta and Saskatchewan, and the dinosaur galleries have an almost unparalleled collection of hadrosaurs, with excellent samples also of the theropods *Gorgosaurus*, *Albertosaurus*, and the slender *Ornithomimus* (which now includes *Struthiomimus*). This fauna is, of course, essentially Upper Cretaceous in age and the Canadian museums therefore lack sauropods and stegosaurs, though the fine series of ceratopsians must be regarded as some compensation.

The Museum of Palæontology was one of those which especially benefited from the 1932 addition. Four large galleries became available: two for vertebrate fossils and two for the invertebrates. Unfortunately, in the past year or two, one of these galleries, so necessary for instruction in a university museum, has been taken over for a museum library. This is all the more regrettable since this hall, and the present invertebrate gallery, have a splendid series of murals of life through the ages, painted by Mr. G. A. Reid.

Dr. Parks was succeeded as director by Dr. Loris Russell, now director of the National Museum of Canada in Ottawa.

The fifth museum was that of Zoology. Housed after 1932 on the spacious top floors of the new addition, it benefited from the imaginative planning of two directors who were also successive professors of zoology. Dr. E. M. Walker, the senior of these, is still active in the Department of Entomology and Invertebrate Zoology and is at present engaged in the preparation of the third volume of his extensive studies of the Odonata. Dr. J. R. Dymond, his successor in the Museum and the professorship, is also very active and occupies an office in the Department of Ichthyology.

A few years ago the Museums of Zoology and Palæontology were united. In 1959 they became the Division of Life Sciences.

Traditionally, botany has received little attention in the Museum. Happily this state of affairs now appears to be ending, and the University Department of Botany, under its chairman, Prof. N. P. Badenhuizen, has generously offered the Museum its cryptogamic and phanerogamic herbaria. At the moment, lack of appropriate space in the Museum has prevented their transfer.

A more positive recent achievement is to be recorded. The Carling Gallery of Reptiles was officially opened by Mrs. C. O. Dalton, wife of the president of Carling Breweries. Without the financial generosity of this Company the gallery of twenty-four dioramas and internally lit cases could not have been prepared and the resulting exhibits show new techniques of casting, recently developed in Toronto by the Display Department under Mr. T. M. Shortt, whose own artistic gifts are seen in the splendid backgrounds to the dioramas.

Fifty years of museum work would not necessarily be of special merit if it were not to be the foundation of things to be continued or to be inaugurated. The Earth Sciences and the Life Sciences can view the future with some confidence. A splendid new gallery of geology will soon be opened. Life Sciences is engaged in planning a series of new dioramas illustrating environments in various zoogeographical zones. These will incorporate materials now in the Museum and the results of expeditions still to be undertaken to several parts of the Old and New Worlds.

Concurrently, the systematic series are being rearranged with emphasis for teaching morphology and taxonomy. In preparation for all this, members of the scientific staff will be visiting type-collections and new exhibits in Europe and the United States and there will be expeditions this year in Alberta and Saskatchewan and field parties to Arctic Canada, the Maritimes and the United States.

The series of special lectures given earlier in the year directed attention to outstanding scientific problems and efforts to solve them. Prof. A. S. Romer inaugurated the series with a masterly account of the evolution of Amphibia. Following speakers dealt with the development of the Pacific Ocean (Prof. H. W. Menard); volcanoes (Dr. Howel Williams); permafrost (Mr. R. Leggett); animal clocks and compasses (Dr. J. Carthy, University of London); and the Moon and space programmes (Dr. G. P. Kuiper).

This heterogeneous series emphasized in a special way the advances in both knowledge and techniques of the past fifty years. Another lecture, given by me in the middle of the series, emphasized the place of the Museum in the interpretation of such advances and pleaded for a new place and regard for museums in the days of the increasing tide of scientific knowledge. How otherwise can the public see the roundness of science and the integration of discoveries? The scientific journals on one hand and the newspapers on the other exhibit extremes for quite different purposes than the elucidation of the whole for lay readers.

The adult population of to-day, who are the responsible body of the electorate and the financial backbone of the State, are largely excluded from knowledge of the circumstances that more and more control their world. Even the graduate of several years standing finds himself in a world in which his own education has often become obsolete. The structure of physics, the range of the Periodic Table in chemistry, the concepts of biochemistry and the more complete series of fossils illustrating evolution, are of fairly recent development. The radio telescope and the electron microscope give new horizons to the universe and its life. Is the public to be excluded from the knowledge and appreciation of the trend and consequences of such advancements ? Although adult education makes an attempt in the largest centres to fill the gaps, television has so far failed to consider meeting the challenge. The museum, with scientifically trained staffs and its three-dimensional exhibits, particularly as in Toronto where there are the resources of a great University behind it, has an almost unrivalled medium of presentation. If such a museum's services be amplified by a planetarium and access to botanical and zoological gardens, a vastly increased service to the public could be given.

In making this 'free university' suitable for public instruction, aided by the Museum's Division of Education, one may tend to overlook its very considerable value to the undergraduate and the graduate student also.

The museum profession, taken eclectically, is competent to make and to maintain such services, but the attainment of the necessary buildings and finance, neither of which is excessive or unreasonable compared, for example, with those of zoological gardens, will never be obtained until a new conception of the museum's place in education and its potential for public instruction is born in the minds of committees and municipal councils.

Perhaps, in Toronto, the new permanent galleries and the temporary special exhibitions, complete with the manifest achievements of fifty years of search and research in many parts of the world, will help toward this desirable end, without which there may be less security for all other institutions in the next few determinant years.

NEWS and VIEWS

Ministry of Works Chief Engineer :

Mr. A. B. Mann, C.B.E.

Mr. A. B. Mann, chief mechanical and electrical engineer of the Ministry of Works, retires on October 26. He joined the Ministry in 1923. Prior to and during the Second World War he was extensively engaged in a senior capacity with the engineering installations and equipment for propellant and high explosive factories at Bishopton, Wrexham, Ranskill, Pembrey and Sellafield, and the emergency military hospitals for the Normandy invasion. In the immediate post-war years he was concerned with the Ministry's programme on behalf of the Ministry of Supply for the construction and equipment of the atomic research establishments at Harwell and Aldermaston, and the factories at Springfields, Capenhurst and Windscale. He was appointed chief engineer in 1954 and assumed responsibility for both the Maintenance and New Works Branches of the Engineering Division. During his term of office a system of planned maintenance was introduced within the Maintenance Branch, and the New Works Branch carried out large-scale and unusual engineering work embracing the new wind tunnels at the Royal Aeronautical Establishment at Bedford, engine test facilities at the National Gas Turbine Establishment at Pyestock, the Rocket Research Establishment at Spadeadam, Admiralty Research Establishments at Bushy Park and Haslar, and Department of Scientific and Industrial Research projects at Feltham, Howbery Park, and the National Physical Laboratory.

Mr. W. L. Wilson, O.B.E.

Mr. Mann is to be succeeded by Mr. W. L. Wilson. He was trained by Imperial Chemical Industries, Ltd. (Billingham Division), and joined the Ministry in 1936. From that time until the end of the Second World War he was engaged at increasing levels of responsibility in the design of Government factories and establishments. He was promoted to the rank of assistant chief engineer in 1954 and since that date has been in control of engineering works undertaken by the Ministry on behalf of the United Kingdom Atomic Energy Authority, the Ministry of Aviation, the War Office and the Department of Scientific and Industrial Research.

Botany at Glasgow : Dr. Samuel Williams

The retirement of Dr. S. Williams at the end of the present academic session after thirty-nine years service on the staff of the Department of Botany, University of Glasgow, will mean a real break with the past. Williams, a native of Nantwich, graduated from Manchester at a time when the staff of the Department of Botany there included Weiss, Lang, Adamson, Thoday, Robinson and Howarth. His appointment to the Glasgow Department came at a period when the staff had been seriously weakened by appointments to chairs elsewhere, with the result that Williams had right away to shoulder a large share of the teaching, which he continued to do with great success until the post-war increase in establishment brought some relief. He has given loyal support to the three heads of Department (Bower, Drummond and Walton) under whom he has served, and has on several occasions taken temporary charge of the Department. Though a botanist of very broad outlook, Williams is, of course, primarily a morphologist and is recognized as an authority on the morphology and anatomy of the Pteridophytes, aspects on which he has published some twenty papers, all of the highest quality, the Neill Medal of the Royal Society of Edinburgh having been awarded to him for this work. He has always been held in the highest esteem by his colleagues because of his botanical competence, his personal integrity and sincerity, and his friendly, generous nature. Mrs. Williams by her most effective demonstrating over many years has also contributed notably to the maintenance of teaching standards in the Department, and it is certain that the gap left by the departure of Dr. and Mrs. Williams will be very hard to fill.

School of Applied Science, University College of North Wales, Bangor

The demand for the course in electrical science at the University College of North Wales has increased considerably in recent years and there is now an annual intake of fifty students. It is proposed in plans for further development to set up a School of Applied Science with three main divisions. In addition to the existing subjects of electronic engineering there will be two new subjects of control engineering and materials technology. Something of these subjects is already included in the present course, but a major step forward has been made by the creation of a new chair of materials technology. Dr. R. W. Cahn, reader in physical metallurgy at the University of Birmingham, has been appointed to the chair of materials technology. Dr. Cahn is a graduate of the University of Cambridge. After three years in the Metallurgy Division of the Atomic Energy Research Establishment at Harwell, he joined the Department of Physical Metallurgy at the University of Birmingham in 1951, where he has held in turn the posts of lecturer, senior lecturer and reader. Dr. Cahn's research work has covered numerous aspects of the crystallography and physical properties of metals and alloys. A chair of control engineering will also be set up in due course. In the development of the new School of Applied Science with the divisions of electronic engineering, control engineering and materials technology it is intended that all technological undergraduates will spend some time in each of the three divisions. It is intended that the emphasis on electronics will remain in the early stages of the new developments. An essential feature of the new plans is to provide opportunities for further study, after the first degree, with M.Sc. courses in various aspects of electronics, control and materials.

Courtaulds, Ltd.: New Research Laboratories

Courtaulds, Ltd., are to transfer the work on basic research now being carried out at Maidenhead to their new laboratories at Coventry. This will ensure closer liaison between basic and applied research staffs and will enable full advantage to be taken of the wide range of facilities available in Coventry. The transfer of staff and equipment, scheduled to begin during the summer, will be completed by the autumn of this year. It has also been decided to concentrate research on petrochemicals and plastics in a new British Celanese laboratory now being built at Spondon, and due to be completed by September. Work in these fields now undertaken in smaller existing research units at Spondon and at Putteridge Bury, near Luton, will be transferred to the new laboratory. After September 30 correspondence should be addressed to the Basic Polymer Research Group, A. and S.F. Laboratory, Courtaulds, Ltd., Coventry, in place of Maidenhead, and to the Research Laboratory, British Celanese, Ltd., Spondon, in place of Putteridge Bury.

London and Home Counties Regional Advisory Council for Technological Education

The thirteenth annual report of the Regional Advisory Council for Technological Education, London and Home Counties, covers the year ended August 31, 1961, and includes a statement of evidence submitted to the Robbins Committee (Pp. 39. London: London and Home Counties Regional Advisory Council for Technological Education, 1962). A plan for the regional development of courses leading to the Diploma in Technology was prepared and published during the year, and comments have been invited from the Regional Academic Board on a draft statement of policy regarding sandwich degree courses. A regional survey of B.Sc. courses has been made. Recommendations have been made and adopted regarding the geographical distribution and demand for degree courses in chemical engineering, as well as courses for the Diploma in Technology and in Technology (Engineering). A report on education for civil and structural engineering in technical colleges in the region is being printed.

Organization and Method in Local Government

The valuable contribution which an organization and methods unit can provide in improving the efficiency of local government services has been described by J. L. Hampshire, County Treasurer of Kent (*Productivity*, 1; January/February 1962. An International Journal and Abstracting Service for Industrial and Business Managers to help Increase Productivity in Factory and Office. Pp. 56. London and New York: Pergamon Press. Annual subscription, six issues, 70*s*.; United States and Canada, 10 dollars). In Kent the Organization and Methods Unit was installed in 1947 and, since then, has carried out investigations in many departments. These include a general reorganization of the Finance Department including the Licences Division, and a general survey of the relationships between the Finance Department and other Departments in such matters as the control of requisitions for supplies and the certification of accounts for payment. Staff members in the Finance and Licences Divisions of the Department were reduced at a time when considerable additional work was being absorbed and the financial savings were considerable. Since 1950, a large number of assignments of a varied character have been carried out. The work has at some time or other affected every County Department, and, although many of the assignments have resulted in ascertainable financial savings, there have been instances where increased effectiveness of the work has been the only aim, and savings, if any, have been of an indirect character. During 1955–56 it was decided to place emphasis on overall departmental investigations while continuing to work on purely subject assignments to meet specific needs and requests. From the beginning it was realized that savings would result from the technique involved. The aggregation of the figures shows that, up to March 31, 1961, realized savings attributable to investigations made by the Organization and Methods Unit amount to approximately £75,900 a year and that suggestions are now under consideration which may involve further savings.

Royal Observatory Annals

Most scientists are aware that fashions in publication have changed in recent decades, and that the general trend is one of publishing less and less detail. Indeed, the growing costs and volume of material that is suitable for publication have compelled many scientific journals to restrict their acceptance of tabular matter to very modest proportions. This is, in many cases, reasonable, but it has thrown a burden on workers in certain branches of astronomy. It is still necessary to make extensive catalogues and observations available to other workers. It is not, therefore, surprising that it has become necessary to start a new publication, *Royal Observatory Annals*, joint publications of the Royal Greenwich and Cape Observatories, published by H.M. Stationery Office (No. 1: *Nutation*, 1900–1959. Prepared by H.M. Nautical Almanac Office. Pp. vii+41. London: H.M.S.O., 1961. 7*s*. net). No. 1, 1961, contains numerical tables of nutation in longitude and obliquity for each day of the period 1900–59, based on new series expansions by E. W. Woolard. The numerical calculations were performed by H.M. Nautical Almanac Office. The new series expansions are being used in the national ephemerides from 1960. The calculations have been extended backwards to enable observers to make improved reductions of recent observations of the Sun, Moon and planets.

New High-power Xenon-Arc Lamp

A new lamp, a compact 5,000-W. xenon-arc lamp, which is nearly three times as bright as the Sun and which will have applications in searchlight and projection equipment, has been developed by the U.S. General Electric Company. The light produced by the lamp totals 275,000 lumens, or 55 lumens/W. The lamp is the second of its kind; the first was a 2,000-W. xenon arc lamp and has been available for several months. Its first use is in a solar simulator for space vehicle investigations. In the visible, the light simulates sunlight, and its total spectrum, including the ultra-violet and infra-red, approximates closely to solar radiation. The lamp has a high degree of stability and of freedom from noise, smoke and fumes. Housed in a parabolic reflector, the lamp throws a powerful beam of light, and, used as a large searchlight, could throw a beam of 10^9 candle-power, sufficient to enable a person to read a newspaper at a distance of about 15 miles from the source. Another expected application is to optical masers. As a source of intense infra-red radiation it will be useful in connexion with solar-type furnaces. The lamp is a direct-current light source in an ellipsoidal-shaped quartz bulb. The bulb is only about 3½ in. in diameter and 4¼ in. in length although the overall length of the lamp is slightly above 19 in. The bulb houses two tungsten electrodes with an arc gap of 8 mm. and the arc operates in a high pressure of xenon. A high voltage is applied to start the lamp and a current of 145 amp. flows across the arc from the cathode to the large anode, which weighs ¾ lb. The anode reaches a temperature of 6,000° F. The lamp is expected to have an operating life of 1,000 hr. Further details of the lamp are available from the International General Electric Co. of New York, Ltd., 296 High Holborn, London, W.C.1.

The First Bragg Lecture

The first public Bragg Lecture (admission free) will be given by Prof. P. P. Ewald, president of the International Union of Crystallography, on the subject "William Henry Bragg and the New Crystallography" at 5.15 p.m. on June 7, in the Arts Lecture Theatre of the University of Leeds, and at 5.15 p.m. on June 13, at the Royal Institution, 21 Albemarle Street, London. The Lecture this year is part of the centenary celebration of the birth of Sir William Bragg. It is also a prelude to the jubilee celebration of the discovery of X-ray diffraction by crystals, to be held in July in Munich, where Prof. Max von Laue suggested and Drs. Friedrich and Knipping carried out their first famous experiment, an experiment which was the result of a question asked by the young research student, Paul Ewald, fifty years ago. The Bragg Lecture will be given once in three years at one or more of the Universities of Cambridge, Leeds, London and Manchester or at the Royal Institution, London, in which places Sir William Bragg and his son, Sir Lawrence Bragg, have carried on their research work. Sir Lawrence Bragg will take the chair on June 13.

British Electrical Power Convention

The fourteenth British Electrical Power Convention will be held in Brighton during June 4–7. The theme of the Convention will be "The British Electrical Industry in the World Scene", and the programme will include: British engineering services overseas (Mr. A. E. Powell, Merz and McLellan); planning for expansion in electricity supply (Mr. R. S. Edwards, Electricity Council, and Mr. D. Clark, Central Electricity Generating Board); automation—the central industrial theme of the '60's ? (Sir Leon Bagrit, Elliott Brothers (London), Ltd.). The Citrine Lecture, "The Snowy Mountains Scheme", will be delivered by Sir William Hudson, commissioner of the Snowy Mountains Hydro-Electric Authority. Further information can be obtained from the press officer, Mr. Stanley Oxley, British Electrical Development Association, 2 Savoy Hill, London, W.C.2.

Announcements

Dr. B. K. Davison has been appointed development chemist in the Development and Research Department of the International Nickel Co. (Mond), Ltd. He is concerned with the chemical and chemico-physical aspects of the Department's work, with particular reference to the established and potential industrial applications of the Company's chemical products. Dr. Davison was formerly organic research manager at Hardman and Holden, Ltd., of Manchester. Previously he was with Imperial Chemical Industries, Ltd., Billingham, and the Imperial College of Tropical Agriculture, Trinidad.

The seventh International Congress on Alpine Meteorology will be held in Sauze d'Oulx-Sestriere, Italy, during September 3–6. Further information can be obtained from the Secretary, Società Italiana di Geofisica e Meteorologia, P.O. Box 3145, Genova.

The National Vegetable Research Station is holding an open day on July 19, when visitors will be able to inspect the laboratories, and see some of the techniques used in a modern research station. Further information can be obtained from Mr. G. Lesson, National Vegetable Research Station, Wellesbourne, Warwick.

A symposium on "Reproductive and Parental Behaviour", arranged by the Association for the Study of Animal Behaviour, will be held in Oxford during July 11–13. The programme will include a visit to the Animal Behaviour Research Group of the Department of Zoology, University of Oxford. Further information can be obtained from Dr. J. B. Free, Rothamsted Experimental Station, Harpenden, Herts.

Errata. In the article appearing in the March 31 issue of *Nature*, entitled "Classification and Nomenclature of Enzymes and Coenzymes", by Prof. R. H. S. Thompson, on p. 1229, col. 1, line 3 from bottom (footnote), "K_{+n}, K_{-n}, velocity constants of . . ." should read "k_{+n}, k_{-n}, velocity constants of . . .", and on p. 1229, col. 2, line 11 from top, "Thus K_{+n} will denote . . ." should read: "Thus k_{+n} will denote . . .".

In the article appearing on p. 372 of the April 28 issue of *Nature* entitled "Determination of Molecular Weights of Gelatin by Scattered Light Measurements", by B. E. Tabor, lines 20–23 should read ". . . $\overline{M}_w$ with respect to the intrinsic viscosity. The replacement of the 0·5 M saline, used by Stainsby, with 1 M potassium thiocyanate . . .".

EXTENSION OF AGRICULTURAL RESEARCH IN QUEENSLAND, AUSTRALIA

A NEW research centre for the Commonwealth Scientific and Industrial Research Organization is to be established at Townsville, in northern Queensland. The centre will fill an important gap in northern Australian research. It will consist of research laboratories and an associated field station of 5,000 acres. The Government will provide a capital sum of £300,000 to finance the venture, and the annual expenditure on research will rise within a short time to £110,000.

The programme of research at Townsville will combine pasture, soil and animal studies. Scientists based at the new centre will work in an area of about one-third of Queensland, extending from Rockhampton to Cape York.

The Organization already has pasture research stations in the Kimberleys, at Katherine, Darwin, Alice Springs, Brisbane, and in the southern States. When the Townsville project is completed, the Organization will be working in every large area of Australia which has a high pastoral potential.

The new laboratories will be built on land adjacent to the University of Queensland's Townsville site. The Government has provided £50,000 this financial year for the purchase of land. The laboratories will have a staff of about fifty, including ten research officers.

The new laboratories and station will become part of the Organization's Division of Tropical Pastures which, under the direction of Dr. J. Griffiths Davies, has carried out pasture research in south-eastern Queensland for several years. The results achieved by this Brisbane-based group have been so promising that the Government now feels it is time to extend the work to northern Queensland.

The research programme will be carried out in the Townsville hinterland, the Cairns hinterland, the northern brigalow lands, the northern speargrass region, and the coastal regions. South of Townsville, the area will extend into central eastern Queensland as far as the northern limits of the area being studied from Brisbane.

The research work will be carried out in collaboration with the Queensland Department of Agriculture and Stock and local graziers. It will include a vigorous programme of testing new introduced pasture species and mixtures. Soil scientists will undertake research into soil deficiencies, and animal and pasture management practices will be studied.

By overcoming stock nutritional deficiencies through the development of improved pasture and fodder crops, this new research programme should help to raise stocking-rates, improve calving percentages, reduce losses to breeders, produce marketable animals at younger ages, increase the percentage turn-over, etc.

At present, more than two million beef cattle, or about one-third of Queensland's beef cattle population, are reared in these regions. It is confidently expected that, in many places, present production can be increased several-fold.

The Organization's Division of Land Research and Regional Survey has already conducted extensive regional surveys in the Townsville and Gulf of Carpentaria areas and is at present making a survey of the Fitzroy Basin in central eastern Queensland. These surveys will provide a basis for future pasture development work.

The research programme will be complemented by the work of the Organization's National Cattle Breeding Station at Belmont, near Rockhampton, and the Division of Entomology's cattle tick research station at Ingham. At Belmont, scientists are studying the selection of cattle for better adaptation to tropical conditions, faster growth-rate, and greater efficiency of food utilization.

THE PRIMATES

A SYMPOSIUM on the primates was held during April 12–14 at the Zoological Society of London, sponsored by the Society in collaboration with the Anatomical Society and the Society for Human Biology. Dr. J. R. Napier, the organizing secretary, had arranged a diverse programme and had invited numerous overseas specialists, some of whom, unfortunately, were unable to be present. This necessitated some changes in the published programme.

The first day, under the chairmanship of Sir Solly Zuckerman, was devoted to aspects of primate behaviour in the wild and in captivity, and included papers by Prof. K. R. Hall (ecology of the chacma baboon, *Papio ursinus*), Jane Morris-Goodall (ecology and behaviour of free-ranging chimpanzees), Rosalie Osborn (behaviour of mountain gorilla), A. Kortland (protohominid behaviour), R. Andrew (evolution of vocalization), J. A. H. van Hooff (facial expression), and the Rev. J. Cole (research on *Macaca nemestrina*). A short film on the so-called ufiti of Nyasaland was shown by Dr. W. C. Osman Hill.

Prof. Hall's contribution added considerably to our knowledge of the social structure, group-composition, feeding behaviour and daily activities of the chacma in several areas of South and South-west Africa, and Southern Rhodesia. Of interest was his observation that in the Drakensbergs baboons range up to the snow-line. Rosalie Osborn exhibited the gorilla film prepared by Dr. Schaller and kindly loaned by the New York Zoological Society. In addition to her commentary, she added remarks on her own first-hand acquaintance with the gorillas in Western Uganda. Emphasis was laid on their essential quadrupedality and lack of brachiation; data were given on feeding activities and nesting procedure.

The well-documented contribution from Miss J. Morris-Goodall was received with much enthusiasm. Her sixteen months close contact with wild chimpanzees in Tanganyika was fully recorded in film and photograph, and the results included convincing evidence of tool-using by the ape. especially application of sticks and straws to probe ants nests for the purpose of collecting the ants for food. There was a noted preferential use of the left hand in this procedure. Also remarkable is the chimpanzee's avidity for salt, which, if available, it will steal. On occasion, flesh is eaten, presumably the local hare or some new-born artiodactyl, and in this there was evidence of sharing of food by a dominant male with his partners.

The morning session concluded with some general discussion opened by Dr. W. C. Osman Hill (who here showed a film and demonstrated a tape recording of the ufiti—a lone chimpanzee recently reported from the Nkata Bay area of Nyasaland). This was followed by an appraisal of the papers by Dr. N. Tappen (Tulane).

The afternoon was devoted to papers by Dr. A. Kortlandt (Amsterdam), Dr. R. Andrew (Yale), J. A. H. van Hooff (Utrecht) and the Rev. J. Cole (Oxford). Kortlandt explained his views on protohominid behaviour based on his field studies of chimpanzees. He posed the question why the great apes have not developed more human behaviour since the basic qualities are available, and compared their cultural progress with that of the australopithecines. His conclusion was that the protohominids were savannah dwellers, an environment evoking new ideas not demanded of forest dwelling pongids. He opined that the great apes could well have been protohominids that had been driven back to the forests.

Dr. Andrew contributed an account of an analysis of the vocal emissions of various primates illustrated by audiograms. He distinguished fundamentals from resonances, giving examples of various utterances by *Cercopithecus, Macaca, Theropithecus* and *Pan*. He concluded that the voice of *Cercocebus* was closer to that of baboons than to *Cercopithecus*, etc.

Mr. Van Hooff outlined the historical development of studies in facial expression since Darwin's classical observations, and gave an account of his personal comparative ethological studies on the higher primates with reference to ætiology, motivation and function. Facial expression could be analysed into movements of brows, eye-region, ears, the erection of coronal tufts and modifications of the mouth, angulus oris and lips Some of the expressions served as social signals.

The Rev. J. Cole held a high opinion of the pig-tailed macaque (*Macaca nemestrina*) as a subject for experimental research, especially in the field of neurophysiology. Outlining some of his experiments, he concluded that: (1) pig-tails show a dominant hand and foot individually varying from right to left; (2) colour has more significance than shape in choice experiments. A decreasing importance of the three sense organs, vision, touch and hearing, in that order, seemed to stem from the effects of the natural environment.

Dr. J. S. Weiner showed a short film loaned by Dr. G. M. Vevers depicting the use of a tool by a captive capuchin monkey. The session terminated in a discussion opened by Dr. M. R. A. Chance.

The morning of the second day, under the chairmanship of Prof. J. Z. Young, was devoted to more specialized topics. In the morning, papers on functional anatomy were delivered. Dr. J. Scott (Belfast) discussed factors determining skull form, paying special attention to the symphyseal region of the mandible, the development of brow-ridges and the recession of the snout, with subsequent changes in the direction of facial growth. In connexion with the latter, he emphasized the role of the septal cartilage which serves as a built-in epiphysis allowing for downward and forward growth and the production of a muzzle. Only in man is the growth vertical in direction.

Dr. C. E. Oxnard (Birmingham) followed with an account of his comparative osteometrical and myological studies of the pectoral limb in reference to locomotor adaptations. This led to a brisk discussion on the definition of brachiation, semi-brachiators and kindred matters. The session concluded with a paper by Dr. G. E. Erikson (Harvard) on brachiation in New World monkeys contrasted with the phenomenon in anthropoid apes. It was pointed out that the higher platyrrhines (*Lagothrix, Brachyteles, Ateles*) are true brachiators. Evidence was specially deduced from studies of the little-known *Brachyteles*. The concluding discussion was led by Prof. A. J. E. Cave.

The afternoon session was devoted to various problems of genetic interest, under the chairmanship of Prof. L. S. Penrose, and opened with a discussion by John Hamerton (Guy's Hospital) on primate chromosomes. Some excellent photographs of gorilla chromosomes were exhibited. Dr. D. Franks (Cambridge) followed with remarks on blood-groups, and admitted that their study gave little information with regard to relationships. He reported that the B group does not appear in *Pan*, while the O group is lacking in *Pongo* and *Hylobates lar*. In *H. moloch* and *Symphalangus* only the B group is present. The A substance in *Pan* is not identical with human A^1 or A^2. The M antigen occurs in the rhesus monkey. As regards the Rh factor, *Gorilla* aligns with man, the other anthropoids do not.

Dr. L. Backman (Uppsala) described new techniques for separation of protein mixtures and discussed results as derived from their application to serum proteins in primates. In electrophoresis experiments he found the speed of transfer of haptoglobin bands was similar in man and baboon, but faster in *Cercopithecus* and some species of *Macaca*; in *Pan* it is slower than in man.

Dr. N. Tappen (Tulane) discoursed on the relations between genetics and systematics in the study of primate evolution, drawing his data from material collected in East Africa. He discussed the chromosome numbers in *Cercopithecus, Erythrocebus* and *Cercocebus* and indicated three or four patterns within the first mentioned. He also drew evidence from paper electrophoresis, which indicated an apartness for *Cercocebus* which had a phenomenally slow-moving hæmoglobin.

The last day, under the chairmanship of Prof. W. Montagna, was devoted to films showing various aspects of primate behaviour. Dr. D. Morris exhibited and made comments on a film depicting chimpanzee behaviour. Dr. W. C. Osman Hill commented on a film taken by Mr. David Attenborough (British Broadcasting Corporation) on his recent trip to Madagascar, and depicting *Microcebus, Lemur fulvus. L. variegatus, Propithecus verreauxi* and *Indri*, the last-mentioned accompanied by a sound track of the peculiar vocalizations. Prof. Hall commented on two films depicting baboon behaviour, one taken on his own expedition, the other originating from Dr. S. L. Washburn (California). The session concluded with Dr. Kortlandt's film of wild chimpanzees.

W. C. OSMAN HILL

VITAL STATISTICS OF ENGLAND AND WALES

THE two volumes of tables for 1960 [1,2], and the commentary for 1959 [3], which the Registrar General issues annually, provide the opportunity for an assessment of the position relating to the population of England and Wales. There are no important changes in the presentation of the statistics, but in the commentary there is one major innovation in the section on mortality. In place of the customary detailed review of mortality by cause of death, there is now a general section dealing with the salient features of mortality, followed by notes on selected special topics; those selected in 1959 being mortality by marital status and deaths from congenital malformation.

Mortality in general continued to decline. One of the principal features of mortality in the 1950's has been the relative stickiness of the death-rates of men over 45 compared with those of women. The following figures illustrate the position, and show that the death-rate of men aged 55–64 is now more than double that of women of the same age:

		1948–50		1958–60	
		Men	Women	Men	Women
Deaths per 1,000	45–54	8·8	5·3	7·3	4·4
population	55–65	22·3	19·5	21·7	10·8
aged	65–74	51·8	34·1	58·5	30·3

Considerable reduction in the mortality from particular causes has been achieved; thus, mortality from tuberculosis has fallen by two-thirds for men, and four-fifths for women in the decade. The growth in mortality from lung cancer in the same period which has increased by 50 per cent for men and 25 per cent for women has already been widely commented on.

The interesting feature of the nineteen-fifties, however, is the behaviour of the birth-rate and of fertility. After the peak of births in 1947, when there were 881,000 live births, the number fell to 668,000 in 1955, but this was followed by an upturn, and from 1955 the number has risen steadily to 785,000 in 1960, a figure which (except for 1947) has not been surpassed since 1921. In his commentary on the 1959 data, the Registrar General still does not commit himself, however, on the question whether this increase in the number of births is a reflexion of an upward trend in family size or of a merely temporary change in the timing of births within marriage. Whichever is true, the rise in the absolute number of births will, of course, result in stresses on the educational system in the late nineteen-sixties and the nineteen-seventies.

It is clear that there is at present no prospect of population growth ceasing, and the projections in the 1960 Population Tables are based on the assumption that after an annual figure of 750,000 births in 1960–65, this figure will gradually rise to 925,000 by the end of the century, and that the population will by that time have reached a figure of 55·6 millions—an increase of nearly 10 million in 40 years. These figures make it all the more important to carry on research into the social and economic factors associated with reproduction. Now that practically all married couples use some form of family planning at some stage of their marriage, predictions about the numbers of future births must take much more account of these factors, if they are to be at all realistic.

THE AMERICAN SCIENTIST

THE March 1962 number of the *American Scientist*, besides celebrating its fiftieth year of publication, celebrates the seventy-fifth jubilee of the Society of the Sigma XI. The president of the Society, Dr. W. R. Brode, contributes a long article discussing the growth of science, as measured in terms of manpower, financial support and facilities, and the implications of a national science programme in terms of changing sources of support and in responsibility for administration and planning. Dr. Brode's comments on the production of publications, the expansion of professional organizations and on the effects of the growth of science on supporting and performing institutions are of wide interest. An article by Dr. E. R. Weidlein, entitled "Co-operation—a Responsibility of the Scientist", starting with the development of the Mellon Institute, reviews the growth of co-operative research in the past half-century.

These two general articles are followed by a series of articles looking to the future of particular fields of science. Prof. G. G. Simpson in "The Status of the Study of Organisms" and Prof. C. Grobstein in "Levels and Ontogeny" look to the future of biology. Prof. S. C. Brown in "Plasma Physics" considers the potentialities of controlled thermonuclear reactions as sources of energy for peaceful purposes. Dr. N. B. Hannay writes on "Chemical Equilibria and Reactions in Semiconductors", Prof. M. Ryle on "Radio-astronomy and Cosmology", including the steady-state theory, and Dr. E. M. Shoemaker describes the geologist's ideas on the exploration of the Moon's surface. Prof. R. G. W. Norrish contributes, under the title "Kinetic Spectroscopy and Flash Photolysis", a summary of his presidential address to Section B at the meeting of the British Association for the Advancement of Science at Norwich last year; J. R. Fresco and D. B. Straus describe the production of synthetic nucleotides as models of the naturally occurring nucleic acids, and Dr. C. D. Cone, jun., the thermal soaring of birds. S. Brunauer contributes an article, "Tobormorite Gel—the Heart of Concrete", and H. M. Wormington a "Survey of Early American Prehistory", while, under the title "European Scientists at Work, 1961", Dr. S. Marcson describes a visit to the Department of Scientific and Industrial Research, to the Philips Research Laboratories at Eindhoven, and to the French Petroleum Institute, Malmaison.

GEL FORMATION IN POLYVINYL CHLORIDE ON IRRADIATION

By M. A. CROOK and B. J. LYONS

British Insulated Callender's Cables, Ltd., Research Organization, London, W.12

CHAPIRO[1] has shown that a large discrepancy exists between the cross-linking and hydrogen chloride yields obtained on irradiation of polyvinyl chloride. He suggested that cross-linking in this polymer occurs through reaction of radicals with unsaturated groups and not by recombination of these radicals.

In recent years a number of papers has been published pointing out that large increases in cross-linking in polyvinyl chloride[2,3] and other polymers[4,5] occur when unsaturated compounds are added, and it seems that some form of polymerization or other chain reaction may be involved.

Recent work carried out in this laboratory has shown that the decay of unsaturation in polythene may be represented as a type of chain reaction[6]. A comparison of gel formation in polythene, polymethyl acrylate, polyvinyl acetate and polyvinyl chloride in the presence of triallyl cyanurate suggests that similar mechanisms of decay of added unsaturation are followed in all four polymers[7].

Charlesby[8] has derived equations relating gel formation to dose for polymers in which insoluble networks are formed by a chain reaction. For a polymer, initially of uniform molecular weight, in which the cross-linking index is proportional to the radiation dose:

$$S \propto \exp(-\gamma) \propto \exp(-KR) \qquad (1)$$

where S is the sol fraction, γ the number of units cross-linked per number average molecule, K a constant and R the dose in megarads. He notes that only slight deviations from this relationship will occur for other molecular weight distributions. Fig. 1 shows that equation (1) represents the variation of sol fraction with dose in the case of a polyvinyl chloride resin examined in this laboratory and for results taken from ref. 9.

Fig. 1 shows that the powder sample gels at a considerably lower dose than the film. This difference may result from: (*a*) greater increases in temperature of the powder during irradiation; (*b*) differences in the surface/volume ratio of the polymer; (*c*) decreases in the molecular weight of the polymer during preparation of the films.

The polymer films were obtained by casting from a solution of the polymer in tetrahydrofurane (distilled twice) at 50° C., all operations being carried out under oxygen-free nitrogen. The films were dried to constant weight in vacuum at room temperature. It is unlikely that large changes in molecular weight occurred during this preparation.

Samples of film surrounded by the polymer powder were sealed under vacuum in ampoules and irradiated. Representative results are given in Table 1.

It appears that the differences result from changes in the surface/volume ratio of the polymer and hence that hydrogen chloride inhibits cross-linking in polyvinyl chloride. Wippler[10] has noted that rigid samples of polyvinyl chloride are more soluble in tetrahydrofurane inside the polymer samples than at the surface.

Table 1. IRRADIATION OF POLYVINYL CHLORIDE POWDER AND FILM TOGETHER

Dose (megarads)	Gel fraction of Powder	Film
10	0·160, 0·149	0·000, 0·000
20	0·780, 0·850	0·534, 0·475

Charlesby also points out that the gel point (δ_{gel}) is related to the gelling dose (R_{gel}) by:

$$R_{\text{gel}} = \frac{\delta_{\text{gel}} i}{1{\cdot}04 \times 10^{-6} G.M_w} = \frac{0{\cdot}5 \times 10^{-6} i^2}{G.M_w} \qquad (2)$$

where the gelling dose is expressed in megarads, G, is the value for chain initiation in events per 100 eV., M_w is the weight average molecular weight and i is an 'amplification' factor which is inversely proportional to the number of links arising from each initiation. When i is below 0·1 gelling doses under 1 megarad are obtained even with quite low values for M_w.

If it is assumed, for the sake of argument, that no chain reaction occurs in polyvinyl chloride alone and a chain reaction with additives is initiated by cross-linking radicals, a comparison of gelling doses with and without unsaturated additives will give an estimate of i. Such a comparison gives i, 0·1: this value is not markedly dependent on the nature of the added unsaturation. It has been suggested above, however, that polyvinyl chloride alone does cross-link by a chain reaction, hence the value for i quoted should be an upper limit. The high gelling dose of the polyvinyl chloride resins examined despite the low value for i suggests that the chain mechanism requires the prior radiolytic formation of unsaturation.

A considerable enhancement of gel formation in polyvinyl chloride when samples are heated to 100° C.

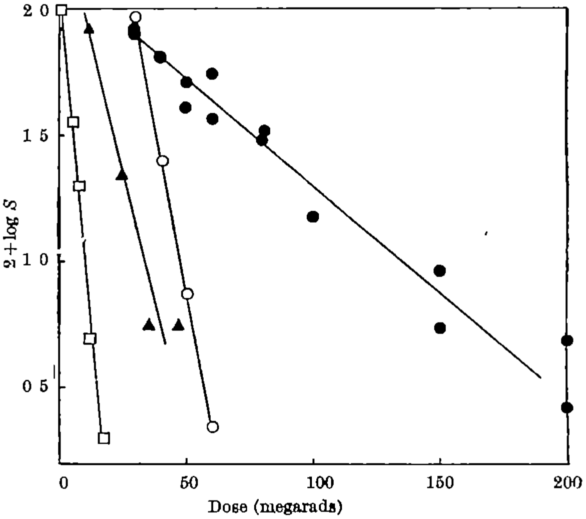

Fig. 1. Variation of log S with dose for polyvinyl chloride polymers. ●, polyvinyl chloride as film, water-cooled vacuum cell, 2 MeV. electrons; ○, polyvinyl chloride as film, in evacuated ampoules 2 MeV. electrons; heated at 50° C. for 30 min. after irradiation; ▲, polyvinyl chloride as powder in evacuated ampoules, no cooling, 2 MeV. electrons, □, polyvinyl chloride powder in vacuum, cobalt-60 gammas, heated at 100° C. for 10 min. after irradiation (ref. 9).

in vacuum after irradiation has been noted by Shinohara *et al.*[9]. These workers estimated the glass transition temperature to be 80° C. and concluded that the increases resulted from a dependence of radical recombination on Brownian motion of the polymer segments. This conclusion is supported by the somewhat smaller increases in gelation which result when polyvinyl chloride is slightly swollen in degassed solvents after irradiation. We have observed significant increases in gel formation accompanied by increased evolution of hydrochloric acid when polyvinyl chloride is heated in vacuum to 50° C. after irradiation. This suggests that the enhancement may be partly due to an increase in unsaturation resulting from the thermal treatment which leads to an increased participation of the 'chain' cross-linking process.

We thank Dr. R. M. Black for his advice and Dr. L. G. Brazier, director of research, British Insulated Callender's Cables, Ltd., for permission to publish this article.

EFFECT OF IMPROVED CARE ON THE PREDICTED ADULT HEIGHT OF UNDERNOURISHED CHILDREN

By Dr. ROY M. ACHESON, GILLIAN B. FOWLER and MARGARET D. JANES

Social and Preventive Medicine Unit, Department of Medicine, Guy's Hospital Medical School, London, S.E.1

LONGITUDINAL investigations in man and experimental animals have indicated that illness, undernutrition and other forms of environmental adversity can stunt adult stature[1]. It has been suggested that this is because growth in stature is relatively slowed more during the period of adversity than is skeletal maturation[2-4]. This article is concerned with the potentiality for, and mechanism of, recovery in a group of German children who were observed during a period of improved care after the deprivations of war[5-7]. The physical development of this experimental group is compared with that of a random sample of children of underground coal-mine workers and of men in professional occupations (drawn from the Medical Research Council's private census[8,9]), who were living a normal life in their own homes in the Rhondda Fach, and who were also examined over a year. Information about the two groups of children is given in Table 1.

Table 2 shows the physical development, by sex, of the two groups of children. Growth represents the increase during the period of observation of standing height in inches, and skeletal maturation is the increase in skeletal age assessed from X-rays of the hand and wrist against the standards of Greulich and Pyle[10]. (Every film was read independently by two of us (R. M. A. and G. B. F.) without knowledge of chronological age, and the two skeletal age values were averaged.) It can be seen that the experimental group grew and matured more rapidly than the comparison group.

Bayley and Pinneau[11] have published tables from which adult height can be predicted on the basis of skeletal age and present height for children aged about seven years and over. These tables assume that the rate of growth relative to skeletal maturation will remain constant (as calculated from a healthy population of American children) from the time of prediction until growth ceases. Therefore, if any environmental factor interferes with the rates of growth and skeletal maturation relative to each other, the predicted height estimated before the interference of the factor will be different from that estimated afterwards. Thus, slowing of growth more than maturation will reduce the predicted height and vice versa. Table 3 shows the changes in predicted adult height in the two populations at the beginning and end of the year; and it can be seen that the predicted adult height of the German boys increased by 0·63 in. during the experimental year ($P < 0.05$), but that none of the other groups of children differed significantly from the expected value (on the basis of the null hypothesis) of zero.

These findings suggest that children of both sexes are capable of growing and maturing at an accelerated rate when their care is improved after suffering from undernutrition. It also suggests that boys, but not girls, increase their predicted adult height during such a period, presumably because they not only grow more rapidly than is usual relative to chronological age, but they also grow more rapidly relative to their skeletal maturation. This is interesting both because previous work[1-3] has shown that boys are more readily retarded than girls in growth and maturation by environmental vicissitude, and because the present evidence bears out an earlier suggestion[3]

Table 1. Age, Skeletal Age, and Predicted Adult Height of 42 Welsh and 42 German Children at the Beginning of the Year

IODINE-131 AND OTHER FISSION PRODUCTS IN DRINKING-WATERS

By R. E. BENTLEY, R. P. PARKER and D. M. TAYLOR

Physics Department, Institute of Cancer Research, Royal Cancer Hospital, London, S.W.3

AND

MARY P. TAYLOR

Radiological Protection Service, Clifton Avenue, Sutton, Surrey

THE appearance of significant amounts of iodine-131 in air, rain-water and milk as a result of the 1961 series of nuclear weapon tests prompted interest in the amount of this nuclide which might be ingested by man from drinking-water. We have measured γ-emitting fission product concentrations in a number of waters, concentrating on iodine-131 owing to its biological importance.

Samples were selected from various parts of England and Wales in two ways. In the first instance, we concentrated on the large cities of Birmingham, Manchester and Liverpool, which draw most of their water from open reservoirs in high-rainfall districts. Secondly, we have considered regions where the transit time from rain-water to consumer is short, such as the Lake District, Southampton and districts supplied from the River Severn. A rough guide to the areas which might show high levels was obtained from the report on *Radiostrontium and Radiocæsium in Drinking Waters*, by Crooks *et al.*[1]. The samples were obtained through the co-operation of the Ministry of Housing, local water engineers, the United Kingdom Atomic Energy Authority, and, in some cases, were drawn directly by us from domestic supplies.

In the first investigations in November 1961, when a guide to the levels of iodine-131 was required quickly, about 1 litre of each sample was assayed using a low-background γ-spectrometer incorporating a 3-in. × 3-in. sodium iodide crystal with a photopeak efficiency for iodine-131 of 3·8 per cent. A range of samples from widely separated points in England and Wales which are listed in Table 1 were assayed during November 1961. In no case was there a counting rate significantly above background in the channels corresponding to the 0·364 MeV. γ-ray of iodine-131. We calculate that under these conditions the limit of detection is 15 $\mu\mu$c./litre.

To increase the sensitivity, an ion exchange method was used to remove the iodine from the water after it had been measured on the 3-in. crystal spectrometer. The resin containing the iodine-131 was then assayed, with a photopeak efficiency of 66 per cent, by counting in a 5-in. diam. × 6-in. high well-type sodium iodide crystal detector coupled to a 100-channel pulse-height analyser.

For the ion exchange separation, carrier iodide (0·5 ml. 0·15 per cent sodium iodide in 0·5 per cent sodium thiosulphate per litre of water) was added together with about 0·1 gm./litre of hydroxy ammonium chloride. After standing for 15–30 min. the water was allowed to flow through a column, 1 cm. diam. × 25–30 cm. high, of the anion exchange resin 'Deacidite *FF*' (Permutit Co., Ltd.), mesh size 15–52, in the chloride form. The flow-rate was adjusted to about 20 ml./min. When all the water had passed through the column the resin was expelled into a suitable sample tube for assay of the iodine-131. Experiments in which water samples 'spiked' with

* Less than 5 $\mu\mu$c./litre for these samples.

1,000 μμc. iodine-131, as sodium iodide, were processed, showed that the resin removed more than 95 per cent of the iodine-131. This method of measurement on about 1·5 litres of six of the samples was insufficiently sensitive to reduce the limit of detection for iodine-131 to less than 5 μμc./litre.

The sensitivity was then further increased by processing 20 litres of each of an additional series of samples by the same method but using a double-sized column. The counting time was increased from 2 to 16 hr. As a check on the method the iodine-131 concentration in a 4·65-litre volume of one of the samples was estimated radiochemically. After addition of carrier iodide and concentration to small volume, the iodide was oxidized with sodium nitrite and nitric acid, and the free iodine extracted into carbon tetrachloride followed by back-extraction into water saturated with sulphur dioxide. The final aqueous extract was assayed for iodine-131 in the 5-in. well counter and the final yield of iodine determined volumetrically after oxidation to iodate. The concentration of iodine-131 in this water sample was found to be 1·8 ± 0·2 μμc./litre by the ion exchange method and 1·8 ± 0·4 μμc./litre by the radiochemical method.

It was observed that, in the ion exchange procedure, ruthenium-103 and the zirconium-95 plus niobium-95 pair were also adsorbed by the resin. Thus values for the concentration of these nuclides were also obtained, using the 0·498 MeV. photopeak of ruthenium-103 and the composite photopeak at about 0·75 MeV. due to the zirconium and niobium. The efficiency of the column in removing these nuclides was estimated by carrying out a similar extraction on rain-water which, on account of its higher specific activity, could be measured both before and after the ion exchange separation. Rain-water was used on the assumption that the elements would be in the same chemical form as in the drinking-waters. The extraction efficiency for ruthenium was found to be 86 per cent and for zirconium and niobium together, 81 per cent.

The results of the measurements made on the 20-litre samples are shown in Table 2 and the activities have been corrected for decay to the time of sampling. When these low-activity samples were measured for 16 hr., the counting error was equivalent to 0·5 μμc. in the case of both iodine-131 and ruthenium-103 and 0·7 μμc. for zirconium + niobium-95. For a 20-litre sample, this corresponds to 0·025 and 0·035 μμc./litre respectively, but the presence of more than one nuclide increases this error. The highest iodine-131 activity measured, 1·8 μμc./litre, was in a sample of water drawn directly from the River Thames at Sutton Courtenay, Berkshire, at a point upstream from the site of discharge of effluent from the Atomic Energy Research Establishment at Harwell. The highest ruthenium-103 and zirconium and niobium-95 values also occurred in river water from the same site. It should be noted that by January 1962 the iodine-131 levels had fallen considerably.

Table 2

Sample		Date sampled	Vol. (l.)	Concentration μμc./l.		
				^{131}I	^{103}Ru	^{95}Zr + ^{95}Nb
Sutton Courtenay, Berks	I.	13.11.61	20	1·8	4·2	3·0
	II.	4.1.62	20	< 0·2	5·9	9·5
Central London	I.	17.11.61	20	0·4	1·8	1·1
	II.	11.12.61	20	< 0·1	2·6	1·6
Sutton, Surrey	I.	19.11.61	20	< 0·3	< 0·05	1·0
	II.	8.2.62	20	< 0·05	< 0·05	~ 0·07
St. Ives, Cornwall		15.1.62	10	< 0·1	~ 0·8	0·5
Southampton		11.2.62	20	< 0·05	~ 0·07	~ 0·3
Bookham, Surrey		11.2.62	20	< 0·05	< 0·05	~ 0·1

The concentration of iodine-131 in all the waters examined is very much less than the maximum concentration of 130 μμc./litre allowed by the Medical Research Council[2] for continuous ingestion in milk by large populations. The concentration in all waters measured is also much less than 82 μμc./litre, which was the mean concentration of iodine-131, measured by us, in milk purchased in the London area throughout the month of November 1961. The concentrations of ruthenium-103 and zirconium plus niobium-95 are an even smaller proportion of the maximum permissible levels (not less than 10^4 μμc./litre (ref. 3)) for these nuclides in drinking-water.

It can be concluded, therefore, that the amounts of iodine-131, and the other nuclides quoted, likely to be ingested in drinking-water from the sources we have examined constitute a negligible hazard to the population.

We wish to acknowledge the interest shown by Prof. W. V. Mayneord and Mr. W. Binks in this investigation.

NATURE OF THE PRECURSORS OF MOLECULAR PRODUCTS IN THE RADIATION CHEMISTRY OF WATER

By Dr. E. HAYON

Department of Physical Chemistry, University of Cambridge

THE nature of the precursors leading to the formation of molecular hydrogen has been much debated since it was found about ten years ago that molecular products are formed in the radiation chemistry of water[1]. A few years ago it was concluded that molecular hydrogen could not be produced from the interaction of excited water molecules ($H_2O^* + H_2O^* \rightarrow H_2 + H_2O_2$), and must result from like species recombination[1], $H + H \rightarrow H_2$, since some solutes (NO^-_3, H_2O_2, Cu^{2+}, Ce^{4+}, acrylamide) could scavenge up to more than 95 per cent of molecular hydrogen. More recently it was suggested[2] that molecular hydrogen is formed from the recombination of two hydrated electrons (the alkaline form of hydrogen atoms) in neutral water, $H_2O^- + H_2O^- \rightarrow H_2 + 2OH^-$. It was thus possible to account[3] for the decrease in the yield of molecular hydrogen with increase in the hydrogen ion concentration, on the basis[3,4] of competition of H^+ for the alkaline form of hydrogen atoms, $H^+ + H_2O^- \rightarrow H + H_2O$. This reaction results in an increase in the dimensions of the 'spurs' in acid solution, compared with neutral solution, and thus reduces the probability of atom recombination. The purpose of this article is primarily to provide further evidence that the primary reducing species in the radiation chemistry of water is the hydrated electron, H_2O^-, and demonstrate that in the radiolysis of water molecular hydrogen is formed by two mechanisms. The main portion results from recombination of the alkaline form of hydrogen atoms (H_2O^-), as suggested above, and about 25 per cent of the total molecular hydrogen via recombination of reducing radicals which are generated initially in the acid form (hydrogen atoms) in the 'spurs' of the radiation.

Hydrogen peroxide and nitrate ions are known to be good scavengers for the precursors of molecular hydrogen[1]. These two solutes have also been shown to react more effectively with the alkaline form of hydrogen atoms (H_2O^-) than with the acid form of hydrogen atoms, when these reducing species are generated both in the radiation chemistry[5] and photochemistry[6] of aqueous solutions. One would therefore expect a change in the rate of scavenging of H_2 by these solutes should the yield of molecular hydrogen be formed from the two different precursors.

Sowden[7] and Mahlman[8] found, using nitrate ions as scavenger for H_2, that a plot of $G(H_2)$ versus cube root of $[NO_3^-]$ showed two linear lines with two different slopes when irradiation was carried out with mixture of fast neutron and γ-rays[7] or cobalt-60 γ-rays[8]. Using hydrogen peroxide as a scavenger for H_2, and plotting the recent data of Anderson and Hart[9] for cobalt-60 rays, $G(H_2)$ versus $[H_2O_2]^{1/3}$, one obtains again two linear lines with two different slopes. It can be seen in Fig. 1 that a major portion (E_1) of molecular hydrogen can be reduced readily by the addition of scavengers, while the remaining portion (E_2) is less susceptible to scavenger concentration. Extrapolation of E_2 to infinite dilution gives $G(H_2)$ 0·1 and 0·12 for nitrate and hydrogen peroxide solutions respectively. The E_2 portion of the molecular hydrogen is higher for H_2O_2 compared with NO_3^- solutions as it includes a $G(H_2) = 0{\cdot}022$ from irradiation of pure (98 per cent) hydrogen peroxide[9]. It seems therefore that the E_2 portion of the molecular hydrogen is a finite quantity for given radiation and that its precursors must be different from those leading to the E_1 portion.

From Mahlman's and Anderson and Hart's results one can readily calculate that the rate of scavenging (the slopes) of the two portions $k(E_1)/k(E_2)$ is $\simeq 10{\cdot}0$ and 7·0 for nitrate and hydrogen peroxide solutes respectively. For nitrate solutions irradiated with mixed neutron and γ-rays[7] $G(H_2)$ at infinite dilution and the E_2 portion are 0·84 and 0·25 respectively, giving $k(E_1)/k(E_2) = 9 \pm 2$. For hydrogen peroxide solutions irradiated with 18·9 MeV. deuterons, E_2 at infinite dilution is $0{\cdot}15 \pm 0{\cdot}02$ (including $G(H_2) = 0{\cdot}025$ from pure hydrogen peroxide), giving $k(E_1)/k(E_2) = 7 \pm 2$. Considering the precursor of the E_1 portion of the molecular hydrogen to be the hydrated electron H_2O^-, and that of the E_2 portion the hydrogen atom, then the ratio of $k(E_1)/k(E_2)$ for nitrate to hydrogen peroxide, that is:

$$\frac{k(H_2O^- + NO_3^-)}{k(H + NO_3^-)} \times \frac{k(H + H_2O_2)}{k(H_2O^- + H_2O_2)} = \frac{10}{7} = 1{\cdot}4$$

Since:

$$\frac{k(H_2O^- + NO_3^-)}{k(H_2O^- + H_2O_2)} = 1{\cdot}0 \text{ (ref. 10)},$$

it follows that: $$\frac{k(H + H_2O_2)}{k(H + NO_3^-)} = 1{\cdot}4.$$

Recently it was shown on introducing hydrogen atoms generated by an electrodeless frequency discharge of hydrogen gas into neutral aqueous solutions of hydrogen peroxide[11] and of nitrate[12] that:

$$\frac{k(H + H_2O_2)}{k(H + NO_3^-)} \simeq 5{\cdot}0$$

which is in fair agreement with the value deduced above from radiation chemistry, considering the different systems and techniques involved and the reproducibility that can be obtained in discharge work. This agreement indicates that in fact the E_1 portion must be a result of recombination of the alkaline form of hydrogen atoms (H_2O^-), and the E_2 portion recombination of the acid form of hydrogen atoms. It provides also independent evidence that the reacting primary reducing species in the radiation chemistry of water is the hydrated electron H_2O^-. This evidence is particularly significant in that it is derived solely from data obtained in neutral solution.

The case that the E_2 portion may be a result of interaction of two excited water molecules ($2H_2O^* \rightarrow H_2 + H_2O_2$ (or 2OH)) and that its reduction with solute concentration is due to energy transfer ($H_2O^* + NO_3^- \rightarrow H_2O + NO_3^{-*}$) is rather weak. Such an event would mean that energy is transferred from water to the solute in a fashion which is directly proportional to the concentration of acceptor up to 20*M*. Further, the yield of the E_2 portion of molecular hydrogen is exactly the same in liquid and frozen solution[8], and its decrease with solute concentration would necessitate that energy be transferred at a rate identical in frozen and liquid solutions. These two premises are not in keeping with present understanding of energy transfer in liquid and rigid media.

On γ-irradiation of nitrate[8] in neutral water and deuterium oxide solutions, $G(H_2)$ and $G(D_2)$ for the E_1 portion are 0·36 and 0·33 respectively; the corresponding values for the E_2 portion are 0·1 and 0·04. As was pointed out[13a] the relaxation time and viscosity are both about 30 per cent larger in deuterium oxide than in water, and this could lead to a more extended initial distribution of the reducing species in the spurs in deuterium oxide compared with water. It follows from this suggestion that in neutral solutions the distribution of the hydrated electron would be much wider in deuterium oxide than in water, thus reducing like and unlike species recombination. In acid solu-

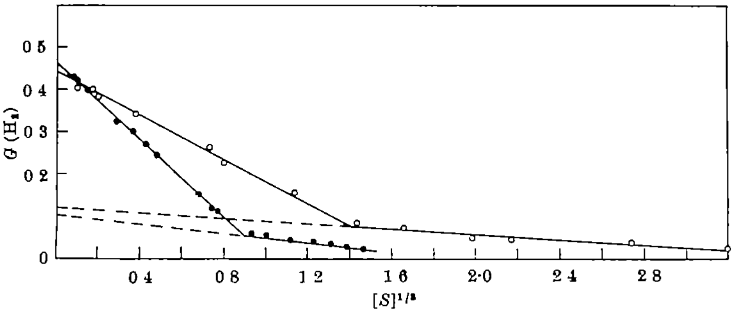

Fig. 1 Cobalt-60 γ-irradiation of neutral air-free solutions of nitrate. (●, data of Mahlman (ref. 8), plot $G(H_2)$ versus ($NaNO_3$ activity)$^{1/3}$) and of hydrogen peroxide (○, data of Anderson and Hart (ref. 9), plot $G(H_2)$ versus $[H_2O_2]^{1/3}$)

tion, the electron would also diffuse away from the core of the spur, but on reaction with acid to form hydrogen (or deuterium) atoms the rate of diffusion of the latter will be significantly less in deuterium oxide than in water. This is supported experimentally: (for γ-rays) GH is 2·9 and 3·7, and G-H_2O 3·82 and 4·44 in neutral[13b,8] water and deuterium oxide respectively; in 0·8 N H_2SO_4[13c] GH is 3·7 and 4·0 and G-H_2O 4·5 and 4·75 in water and deuterium oxide. Similarly, if the hydrogen atom is formed initially in the spurs its diffusion and probability of recombination will also be reduced in deuterium oxide compared with water, as the results[8] for the molecular hydrogen yields of the E_2 portion indicate.

The E_1 portion of the molecular hydrogen can be eliminated on irradiation of neutral aqueous solutions of nitrate[8] and hydrogen peroxide[14a] at 77° K. The yield of nitrite has also been shown[14b] to increase with increase in [NO_3^-] at 128° K. These observations suggest that some activation energy may be required for the recombination of two H_2O^-, and as a result of the greater mobility of electrons compared with hydrogen atoms they can diffuse to nitrate ions and yield nitrite[14b]. Therefore molecular hydrogen is formed via E_2 only in neutral solutions at 77° K.

In acidified aqueous solutions γ-irradiated at 77° K.[15] (as a glass) the yield of molecular hydrogen is considerably greater than in neutral solution at 77° K., indicating that the hydrated electrons are stabilized by hydrogen ions to form hydrogen atoms, most of which recombine to give hydrogen on warming. EPR measurements support the above in that unpaired-electron species related to hydrogen atoms can be detected in aqueous solutions irradiated at 77° K. in acid medium[15] but not in neutral[15,16]. On γ-irradiation of ice at 4·2° K.[16], however, the paramagnetic resonance absorption spectrum indicates the trapping of hydrogen atoms (which have not been distinguished from H_2O^- by EPR). At this very low temperature the diffusion of electrons is very much reduced[17], and hence they are trapped and measured by EPR. Livingston and Weinberger[15] also found that addition of hydrogen peroxide or nitrate to acidified aqueous solutions irradiated at 77° K. greatly suppresses the yield of atomic hydrogen (and of molecular hydrogen) as measured by EPR, though on irradiation at room temperature under otherwise similar [H^+]/[S] ratios these solutes are relatively unreactive to reducing species in acid solutions[5]. On the model presented here this means that at 77° K. the electron diffuses to reactive sites. On encountering a hydrogen ion it reacts to form a hydrogen atom (which is detected by EPR), or the electron on encountering hydrogen peroxide or NO_3^- will react with them preferentially before it has been converted to a hydrogen atom in acid solution since results (ref. 15 compare Figs. 2, 11 and 12) show that H^+ is a less effective trap for the electrons at 77° K., compared with room temperature. Furthermore, Figs. 11 and 12 (ref. 15) show that about $\leqslant$ 20 per cent of the hydrogen, that is $G(H_2) \leqslant 0·12$, is scavenged by hydrogen peroxide and nitrate at a much lower rate than the remaining hydrogen.

In the E_2 portion of the molecular hydrogen, the hydrogen atoms are generated initially in the acid form, probably from the dissociation of excited water molecules, $H_2O^* \rightarrow H + OH$. The formation of initially generated hydrogen atoms and its reaction with solutes in the bulk of the solution have recently been discussed[18,4] (Hayon, *J. Amer. Chem. Soc.*).

Table 1

	Neutral pH		0·8 N H_2SO_4		
	G-value*	Per cent of G-H_2O	G-value†	Per cent of G-H_2O	$\frac{G \text{ acid}}{G \text{ neutral}}$
G H_2	0·45	11·7	0·40‡	8·9	0·89
G H_2O_2	0·71	18·7	0·80	17·8	1·13
G H	2·90	38·1	3·65	40·5	1·26
G OH	2·40	31·5	2·95	32·8	1·23

The situation with regard to the nature of the precursors of molecular hydrogen peroxide is much less conclusive, owing to the scarcity of relevant data. The position corresponding to the reducing species would be that the basic form of the oxidizing species (H_2O^+) be more prevalent in acid solutions, while in neutral-alkaline solution it would be present to a larger extent as OH radicals[2]. Available experimental results are not in contradiction with the above, when these oxidizing species are formed in acid or neutral solutions in photo-chemistry as well as radiation chemistry[19]. The rate of scavenging the precursors of molecular hydrogen peroxide in dilute solutions of bromide is greater in acid solution by a factor of 1·7 compared with neutral solution[10]. This probably means that the rate of recombination of the precursors of molecular hydrogen peroxide is smaller in acid solution compared with neutral and that they are intercepted more readily by Br^- ions. On the other hand, the percentage of the oxidizing species (on the basis of net decomposition of water) that recombine to form hydrogen peroxide is very slightly larger in neutral solution compared with acid (Table 1, columns 3 and 5). This could be ascribed to the higher rate of recombination of OH radicals in neutral solutions.

Some indication can also be provided from a comparison of the hydroxylation in the o-, m- and p-position of aqueous solutions of benzoic acid, nitrobenzene, and chlorobenzene when differences in the mesomeric and inductive effects on substitution can be considered. The relative yields of the isomeric hydroxylation products follows a similar trend when these products are formed by Fenton's reagent, photolysis of hydrogen peroxide, or X- and γ-irradiation of aqueous solutions in neutral-alkaline pH (in all cases the OH radical is presumably formed), whereas the relative yields on irradiation of acidified solutions are somewhat different[20] (when the H_2O^+ oxidizing species is possibly prevalent).

Recent results[21] of the scavenging of molecular hydrogen peroxide on irradiation of oxygen-18-water in acid and alkaline solution in the presence of a number of solutes suggest that hydrogen peroxide is probably also formed from two different precursors which are scavenged by the solute at different rates. The departure of the experimental points of the yields of molecular hydrogen and hydrogen peroxide at relatively high solute concentration from the calculated curve in the Schwarz plot[22] supports also the foregoing conclusion that the molecular products are formed from the recombination of two different precursors.

From the interpretation of the results presented here it follows that the rates of the three reactions $H + H \rightarrow H_2$, $OH + OH \rightarrow H_2O_2$, $H + OH \rightarrow H_2O$ must be different from one another, and depend on pH and the kind of precursor involved. Thus the rate constant for recombination of unlike species to form water would be expected[23] to be higher in neutral than in acid solutions.

Finally, from the evidence showing that the primary reducing specie in the radiation chemistry of water is the hydrated electron H_2O^-, and since it has been shown[6] that the reducing specie formed in the photochemistry of neutral aqueous solutions of iodide ions is identical with that formed in the radiation chemistry of water, one can for the first time demonstrate in the photochemistry of aqueous solutions of ions[24] the absorption spectra of which are 'electron affinity spectra' that the reacting primary reducing species are the alkaline form of the hydrogen atom, H_2O^-. This hydrated electron seems to be identical with that formed in the radiation chemistry of water, and can be converted to a hydrogen atom on reaction with a hydrogen ion in acid solutions[25].

I thank Dr. A. O. Allen for reading a manuscript of this article.

PRESYNAPTIC INHIBITORY ACTIONS

Presynaptic Inhibitory Action of Cerebral Cortex on the Spinal Cord

It has long been known that activation of the cerebral cortex, particularly of the sensori-motor area, results in powerful excitatory and inhibitory actions on interneurones in the spinal cord[1,2]; but it remained for Hagbarth and Kerr[3] to demonstrate that stimulation of the somato-sensory area of the cortex and various other regions of the brain inhibited the synaptic actions that evoked discharges up several ascending tracts of the spinal cord. This whole field has recently been reviewed by Hagbarth[4]. Since then there have been many investigations[5-9] showing that, particularly in the decerebrate cat, impulses descending in the lateral columns of the cord exert powerful tonic inhibitory influences on most interneuronal pathways.

It was suggested[10] that the descending inhibitory influences reported above[3,4] might be due to a presynaptic inhibitory action on the primary afferent fibres. The present investigation has established the correctness of this suggestion in respect of the effects of cortical stimulation, and it also leads to the further suggestion that the descending tonic inhibitory influences might largely be effected by presynaptic inhibition.

The experimental procedures on cats anaesthetized with 'Nembutal' resembled previous investigations on presynaptic inhibition in the spinal cord[11,12] with in addition the exposure of the cerebral cortex, so that it could be stimulated by brief trains of repetitive pulses (usually 6 at 300/sec.) applied through bipolar electrodes with 2 mm. interpolar distance. As shown in Fig. 1*A*, stimulation of the contralateral cortex evoked a potential change in an isolated dorsal rootlet which closely resembled the dorsal root potential produced in that same rootlet by repetitive group I volleys from the nerve to a flexor muscle (*B*) and by a single volley in an ipsilateral cutaneous nerve at that segmental level (*C*). Stimulation of the arm area of the somato-sensory cortex produced a dorsal root potential of the dorsal rootlets supplying the contralateral arm, but not the leg (*D*); and similarly with the cortical leg area and the dorsal rootlets for the contralateral leg and arm (Fig. 1*E*). The diameters of the filled circles on the cortical map (Fig. 1*F*) give the effectiveness of the underlying areas in evoking dorsal root potentials in a dorsal rootlet at L_7 segmental level, and show the restriction to somato-sensory leg areas I and II. The same areas of the ipsilateral cortex were also effective in producing a dorsal root potential, but to a lesser degree. This somatotopic organization corresponds well with that reported for inhibitory influences on the ascending pathways[3,4]. No other active cortical foci have been recognized; but as yet only the convexity of the cerebrum has been explored.

Since dorsal root potentials arise due to the electrotonic transmission of a synaptic depolarizing action on the central terminals of the primary afferent fibres[11,12], it may be predicted that there would be a corresponding increase in excitability of these terminals. Using the method of testing developed by Wall[13], it was possible to identify the types of primary afferent fibre that were depolarized by various afferent inputs into the spinal cord[11]. Similarly, it has been shown (Fig. 1*G*) that dorsal root potentials elicited by cortical stimulation are produced by a depolarizing action on the cutaneous

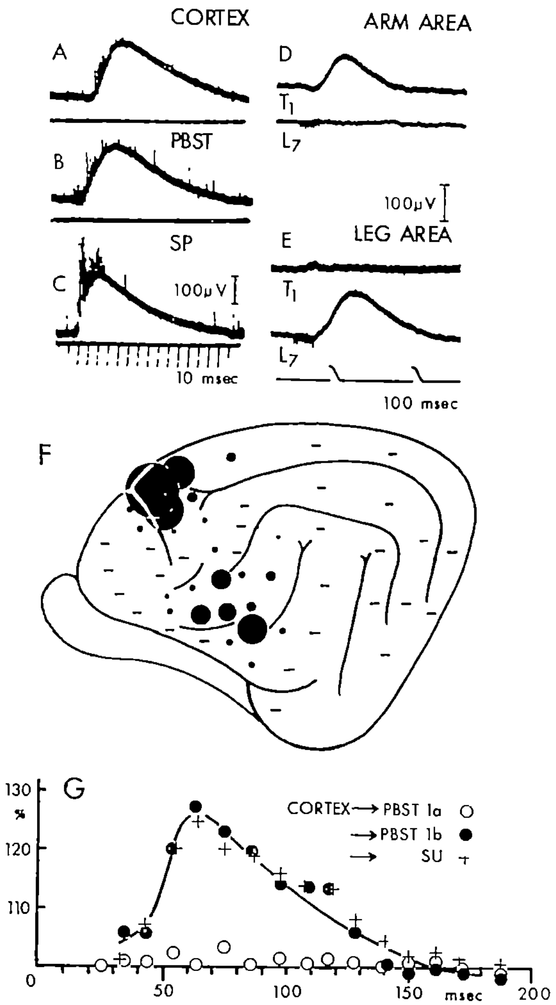

Fig 1. *A–C* show dorsal root potentials led from a L_7 dorsal rootlet which was isolated except for its cord entry and recorded by two electrodes, one about 1 mm. from the cord, the other on the distal cut end. There was brief repetitive stimulation of the contralateral cortex, *A*, and of posterior biceps semitendinosus nerve, *B* (PBST), as described in text; in *C* a single volley in the superficial peroneal nerve. *D* gives dorsal root potentials produced by repetitive stimulation of contralateral cortical arm area with similar recording from dorsal rootlets of first thoracic (T_1) and L_7 segments, while in *E* the contralateral cortical leg area was stimulated. In *F* the sizes of the dorsal root potentials produced in a L_7 dorsal root of the contralateral side are shown by sizes of filled circles for stimulating sites over the convex surface of the cortex, zero actions being shown by – signs. *G* shows that the time courses of excitability changes produced by cortical stimulation in two types of fibre (●, + points) resemble the dorsal root potential in *A*. There was no action on the third fibre type (○ points). Percentages are measured as described previously (ref. 11); time is measured from the first stimulus of the conditioning tetanus

afferent fibres (+) and on the *Ib* afferent fibres from muscle (●), but not on the *Ia* muscle afferents of either flexor or extensor muscles (○). The observed increases in excitability (range 120–135 per cent) have been almost as large as those induced by afferent volleys in large limb nerves, which corresponds to the relative magnitudes observed for the dorsal root potentials (Fig. 1*A–C*). There is convincing experimental evidence that presynaptic depolarization has a depressant action on the liberation of the synaptic transmitter, giving as a consequence the so-called 'presynaptic inhibition' of synaptic transmission[11,14–16].

It may therefore be concluded that, as a consequence of the induced dorsal root potential, cortical stimulation also achieves an effective presynaptic inhibitory action on the spinal cord, which would explain the observations already cited[3,4]. Presumably this cortical inhibitory influence acts through the same spinal interneuronal pathways[1,2,17] which are responsible for the presynaptic inhibitory action which volleys from limb nerves exert on *Ib* and cutaneous afferent fibres[11,12,15].

It has already been shown that presynaptic inhibition of *Ia* synaptic action is effected through a distinctive pathway[11,13,14], which apparently is not influenced from the cortex. It will be appreciated that this independence of the *Ia* pathway from presynaptic inhibitory action descending from the cortex parallels the independence of the *Ia* pathway from the tonic inhibitory influences that, descending from higher centres, tonically depress transmission through the central pathways of cutaneous and *Ib* afferent impulses[5–9]. The question therefore arises whether some of these tonic inhibitory influences are exerted also by the mechanism of presynaptic inhibition, and not only by postsynaptic inhibition as hitherto has been supposed.

Presynaptic Inhibition in the Cuneate Nucleus

IN the pathway from cutaneous nerves to the sensory cortex a conditioning volley is followed by a deep and prolonged (about 150 msec.) depression of the primary cortical response evoked by a testing volley in the same nerve or in another nerve of that limb[1–4]. Much of the depression has been shown to occur in the relay of the pathway in the ventro-basal nucleus of the thalamus, and indeed Amassian[3] found little or no depression of the responses to the testing volley recorded in the medial lemniscus after synaptic relay in the cuneate nucleus. However, Marshall[1] illustrated an indubitable depression which had a time course resembling that observed for the primary cortical potentials, though much less in degree, and inhibition of about 200 msec. in duration has been observed in the discharges of cells in the gracile nucleus[5]. Cutaneous afferent volleys were found by Therman[6] to produce on the surface of the cuneate nucleus a large positive wave which had a time-course resembling the depression of synaptic transmission, but this equivalence was regarded as fortuitous because the positive wave was believed to arise

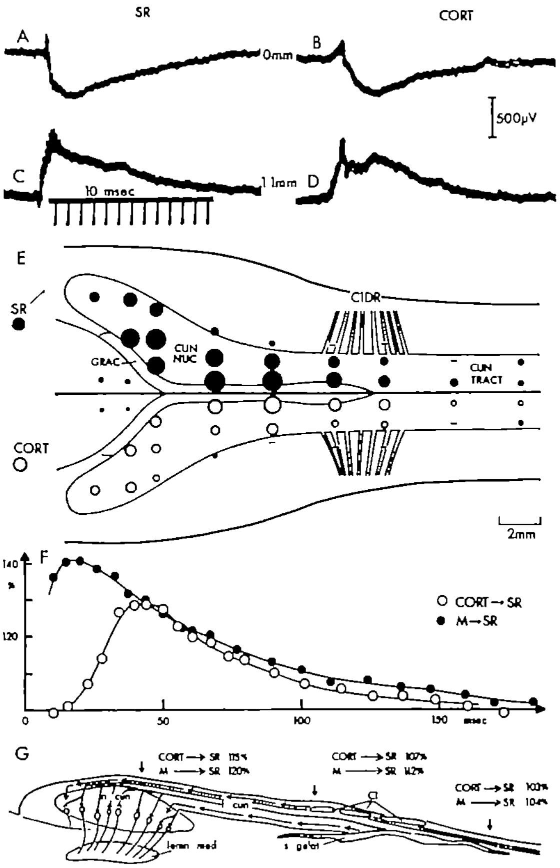

Fig. 1. *A*, *B* are potentials led by a glass microelectrode from the surface of the cuneate nucleus and evoked by a single volley in the superficial radial nerve (*SR*) and by repetitive stimulation of the contralateral sensori-motor cortex (*CORT*), while with *C*, *D* the microelectrode tip was at a depth of 1 1 mm. Potential and time-scales are for *A–D*. In a drawing (*E*) of the dorsum of the cuneate nucleus (*CUN NUC*) and its environment, the sizes of the *P* waves produced by *SR* and *CORT* are shown as described in the text, zero responses being shown by – signs. *CIDR* is first cervical dorsal root. *F* gives time courses of the excitabilities of presynaptic terminals in the cuneate nucleus which were measured as percentages of the control excitability as already described (ref. 8), and plotted against time after the first conditioning stimulus. *G* is drawn from a sagittal section of the cuneate tract and nucleus, *C*1 showing first cervical root. Excitability changes of the *SR* fibres were tested as in *F* at the three sites indicated by the vertical arrows, and the increases are shown at a testing interval of 51 msec. for *CORT* and 45 msec. for *M*

in the underlying reticular substance. The present study of the cuneate nucleus was prompted by the idea that these observations pointed to the existence of a presynaptic inhibitory mechanism in the cuneate nucleus comparable with that in the spinal cord[7–10].

Furthermore, the same interpretation seems likely for the inhibitory action exerted on the cuneate and gracile nuclei from the contralateral sensori-motor cortex[11,12].

As described by Therman[6] an afferent volley in a cutaneous nerve of the fore-limb produced a characteristic series of potential waves on the surface of the cuneate nucleus. The brief initial spike potential of the primary afferent volley was followed by a negative (*N*) wave of several milliseconds duration and a prolonged positive (*P*) wave, which reached a maximum at 20–30 msec. and was about 200 msec. in duration (Fig. 1*A*). Brief repetitive stimulation (6 stimuli at 300/sec.) of the contralateral sensorimotor cortex produced a *P* wave having a similar time course (Fig. 1*B*). When the microelectrode was advanced from the surface to the depth of the cuneate nucleus, the *P* waves evoked by cutaneous volleys and from the cortex both reversed to negative potentials having comparable time courses (Fig. 1*C*,*D*).

When the surface electrode was moved over the surface of the cuneate nucleus and adjacent parts of the medulla and spinal cord, the *P* wave was found to decline very steeply laterally and also rostrally, but it extended with a progressive decrement and for a relatively long distance caudally along the cuneate tract. The same distribution occurred for the *P* waves produced by cutaneous volleys and cortical stimulation, as indicated by the filled and open circles in Fig. 1*E*, in which the sizes of *P* waves were represented by diameters of the circles. This distribution along the presynaptic pathway to the cuneate nucleus suggests that the *P* wave is generated in the presynaptic fibres of the cuneate tract, and that in its genesis the *P* wave in the cuneate nucleus is comparable with the *P* wave of the cord dorsum. This suggestion was tested by investigating by Wall's method[13] the changes in excitability of the primary afferent fibres in the cuneate nucleus and at various more caudal levels down to the upper part of the *C*2 segment.

As with primary afferent fibres in the spinal cord[8,13], conditioning by a cutaneous afferent volley or by repetitive cortical stimulation caused a prolonged increase in the excitability of the terminals of the cuneate tract. For example, in Fig. 1*F* (● points) a volley in the median nerve produced an excitability increase in the primary afferent terminals of the superficial radial nerve in the cuneate nucleus, which had a time course resembling the *P* wave in Fig. 1*A* or its inverted (negative) counterpart in Fig. 1*C*. A comparable change in excitability was found by Wall[13] in the gracile nucleus. Similarly, repetitive cortical stimulation caused the excitability increase in the superficial radial nerve (Fig. 1*F*, ○ points) with a time course resembling that of Figs. 1*B* and *D*. It can be concluded[8,13] that the curves of Fig. 1*F* plot the time-course of depolarization of the primary afferent fibres of the superficial radial nerve. When testing the excitability of the superficial radial fibres at various sites along their length, the greatest change occurred in the neighbourhood of their synaptic terminals in the cuneate nucleus. There was progressively less change with more caudal testing sites (Fig. 1*G*,) whether conditioning was by cutaneous volleys or by cortical stimulation.

As shown by the arrows in Fig. 1*G* a depolarization produced in the terminals of the presynaptic fibres of the cuneate nucleus would result in the extracellular flow of current indicated by the arrows so that this depolarization would spread electrotonically along the presynaptic fibres, and give the decrementing depolarization revealed by the excitability tests. Furthermore, this current would result in the observed field potentials—the negativity within the cuneate nucleus and the surface positivity that progressively decremented along the course of the cuneate tract (Fig. 1*E*). These tests indicate that the primary afferent terminals in the cuneate nucleus are subjected to the same depolarizing mechanism as in the spinal cord[8,9], where it has been shown to be responsible for presynaptic inhibition by depressing the output of transmitter[7,10,14]. The present investigation of the presynaptic inhibitory action on synaptic transmission through the cuneate nucleus has confirmed Marshall[1] and Towe and Jabbur[12] in showing that the postsynaptic spike response exhibits an increase in latency and a decrease in number of impulses that parallels the presynaptic depolarization, the maximum action being at about 20–30 msec. and the total duration of about 200 msec. The *P* wave produced by the testing volley exhibits a comparable depression, which was also observed by Therman[6] and which parallels that found in the spinal cord[10].

The present results further suggest that the cortical inhibition of the cuneate nucleus[12] is effected by presynaptic inhibition. The pathway has been shown to be from the sensori-motor cortex to the cuneate nucleus largely via the pyramidal tract[11,15–17]. On analogy with presynaptic inhibition in the spinal cord[9], it is likely that, in the cuneate nucleus or adjacent thereto, all the pathways giving presynaptic inhibition pass through several interneurones. From interaction experiments it seems that the cuneate tract fibres and the descending fibres from the cortex act through the same system of interneurones. Jabbur and Towe[17] found that some cuneate and gracile neurones were excited to discharge both from the sensori-motor area of the cortex and also from peripheral nerves. These neurones have properties that correspond with the interneurones in the spinal cord that are postulated to be on the presynpatic inhibitory pathway[9]. Alternatively, the interneurones of the presynaptic inhibitory pathway might be in the reticular substance subjacent to the cuneate and gracile nuclei[12,16].

Finally, it is postulated that these interneurones make synapses on the axons of the cuneate tract close to their synaptic terminals, and that activation of these axo-axonic synapses results in the observed depolarization of the cuneate tract fibres. Recently, axo-axonic synapses of the type postulated have been observed by Gray[18] and Szentagothai (personal communication) at other sites in the central nervous system.

AN ABNORMAL HUMAN FŒTAL HÆMOGLOBIN WITH AN ABNORMAL ALPHA-POLYPEPTIDE CHAIN

By Prof. HELEN M. RANNEY, CATHLEEN O'BRIEN and ALAN S. JACOBS

Albert Einstein College of Medicine and Bronx Municipal Hospital Center, New York 61,
and University of Vermont College of Medicine, Burlington, Vermont

THE hypothesis that the α-chains of human fœtal hæmoglobin are identical with those of adult hæmoglobin[1] implies that cord blood obtained from an infant heterozygous for an α-chain abnormality would exhibit two different fœtal hæmoglobins[2,3]. These postulated fœtal hæmoglobins would result from the union of normal γ^F-chains with normal or abnormal α-chains. An example of such a cord blood constitutes the subject of this communication.

During an investigation of fœtal hæmoglobins in Burlington, Vermont, we encountered the cord blood of C. S., a male infant, in which, at *p*H 8·6, an electrophoretically 'rapid' abnormal component comprised 23 per cent of the hæmoglobin[4]. This component exhibited somewhat greater anodal mobility at *p*H 8·6 than did a sample of known hæmoglobin Bart's (γ_4^F).

Hæmatological investigations, including determinations of hæmoglobin F and A_2, were carried out on blood samples obtained from the mother, both maternal Italian-born grandparents, the father, O. S. (of northern European ancestry), and two siblings of the propositus. The only abnormality detected in these studies was the presence of an electrophoretically 'rapid' component amounting to about 20 per cent of the total pigment in the hæmoglobin of the father and of a two-year-old sister (Fig. 1). At *p*H 8·6 the 'rapid' component of the father's hæmoglobin exhibited slightly greater electrophoretic mobility than the 'rapid' cord component, and approximately the same mobility as hæmoglobin H. However, at *p*H 6·5, the father's abnormal component migrated toward the cathode. In accordance with recent recommendations concerning nomenclature of hæmoglobin[5], the 'rapid' component of O. S. was designated hæmoglobin $\text{I}_{\text{Burlington}}$.

In an attempt to delineate the relationship of the 'rapid' cord hæmoglobin to hæmoglobin $\text{I}_{\text{Burlington}}$, comparative studies were carried out on the hæmoglobin of O. S. (father) and of C. S. (cord blood) and on designated hæmoglobin components as isolated by starch block electrophoresis.

Determinations of alkali resistance were carried out on the total hæmoglobins[6], and on isolated components[7]. The results are shown in Table 1.

Table 1. Per cent Alkali Resistance of Total Hæmoglobins and of Isolated Components

C. S. cord hæmolysate			O. S. father's hæmolysate		
Total	Main F + A	'Rapid'	Total	Main (A)	'Rapid' (Hb.$\text{I}_{\text{Burl.}}$)
70	76	68	2	5	5

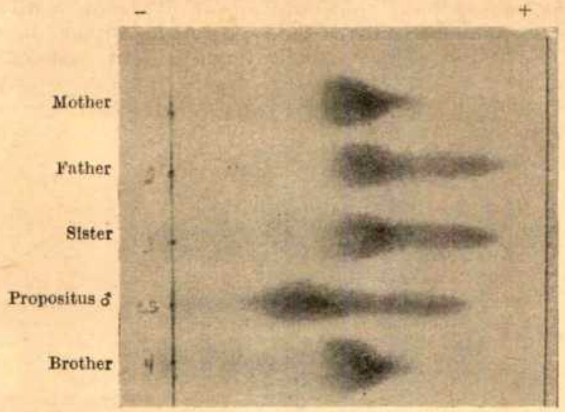

Fig. 1. Filter paper electrophoresis of C. S. family. Electrophoresis between glass plates for 6 hr. at 450 V. Bromphenol blue stain. Barbitol buffer, pH 8·6

In summary, the cord hæmoglobin and its components were about 70 per cent alkali resistant. Neither the total hæmoglobin of the father nor its A or I component exhibited significant alkali resistance.

Recombination experiments were carried out by a modification[8] of the method of Itano and Robinson[9]. Electrophoretically purified hæmoglobin $\text{I}_{\text{Burlington}}$ and hæmoglobin S were mixed, and half of the mixture acidified to pH 4·7. After the recombined and control (unacidified) mixtures had been dialysed against phosphate buffer at pH 6·8, electrophoretic analyses were carried out on cellulose acetate in veronal buffer pH 8·6 and on starch-gels, at 4° C., in borate buffer pH 8·8. In both cellulose acetate and starch-gel analyses, two new hæmoglobin components, both of electrophoretic mobility between S and I, were identified (Fig. 2).

Since new hæmoglobins were found after recombination of hæmoglobin S, which has an abnormality in the β chain, with hæmoglobin $\text{I}_{\text{Burlington}}$, the abnormality in the latter hæmoglobin must reside in the α chain. Thus:

$$\underset{\text{Hb. S}}{\alpha_2^A\,\beta_2^S} + \underset{\text{Hb.}\text{I}_{\text{Burl.}}}{\alpha_2^I\,\beta_2^A} \rightarrow \underset{\text{Hb. S}}{\alpha_2^A\,\beta_2^S} + \underset{\text{Hb. A}}{\alpha_2^A\,\beta_2^A} + \underset{\substack{\text{Doubly}\\ \text{Abn. Hb.}}}{\alpha_2^I\,\beta_2^S} + \underset{\text{Hb.}\text{I}_{\text{Burl.}}}{\alpha_2^I\,\beta_2^A}$$

The doubly abnormal hæmoglobin $\left(\alpha^I\beta_2^S\right)$ migrated between hæmoglobin A and hæmoglobin $\text{I}_{\text{Burlington}}$ in this work. Examples of hæmoglobin I examined by others have been found to yield two new components on recombination with hæmoglobin S[8,9]. In the sample of hæmoglobin I examined by Murayama[10], the abnormality was the substitution of aspartic acid for lysine in residue No. 16 of the α-chain.

Recombination experiments utilizing hæmoglobin S and the 'rapid' cord component were also carried out. While new hæmoglobin species were apparently formed, these components did not appear to be identical with the new components from the recombination of hæmoglobin S and hæmoglobin $\text{I}_{\text{Burlington}}$ (Fig. 2). Other investigators have reported incomplete hybridization in experiments involving hæmoglobin F (ref. 3). Moreover, evidence will be cited (*vide infra*) that the 'rapid' cord component of this work contained α-chains together with both γ- and β-chains. We have therefore not attempted to designate by formulæ the components resulting from recombinations of 'rapid' cord hæmoglobin and hæmoglobin S.

N-terminal amino-acid determinations were carried out on the 'rapid' cord component and on hæmoglobin $\text{I}_{\text{Burlington}}$ by the dinitrophenyl (DNP) method of Sanger. In hæmoglobin $\text{I}_{\text{Burlington}}$, only DNP-valine was found, as might be anticipated for $\alpha_2^I\beta_2^A$ composition. In contrast, both DNP-valine and DNP-glycine were identified in the 'rapid' cord component. The presence of DNP-glycine indicated the presence of γ-chains in the 'rapid' cord component[1].

A Beckman–Spinco amino-acid analyser was used for amino-acid analysis of a 22-hr. hydrolysate of globin prepared from the 'rapid' cord component. The results of this analysis were compared with published analyses of hæmoglobin F (ref. 11) and hæmoglobin A (ref. 12). A significant finding in the amino-acid analysis of the 'rapid' cord component was the presence of 6 isoleucine residues/mole of hæmoglobin. Since each γ^F chain contains 4 isoleucine residues, and isoleucine is absent in both α^A and β^A chains, the finding of 6 isoleucine residues is compatible with the presence of α-chain dimers with γ-dimers or β-dimers in a 3 : 1 ratio. This 3 : 1 ratio of γ- to β-chains would also fit the alkali resistance data (± 70 per cent) and the DNP–glycine data. While our recovery of total amino-acid residues was inexplicably high (106 per cent compared with hæmoglobin F (ref. 11)), the residues/mole of amino-acids other than isoleucine were also compatible with a theoretical 3 : 1 mixture of hæmoglobins F and A.

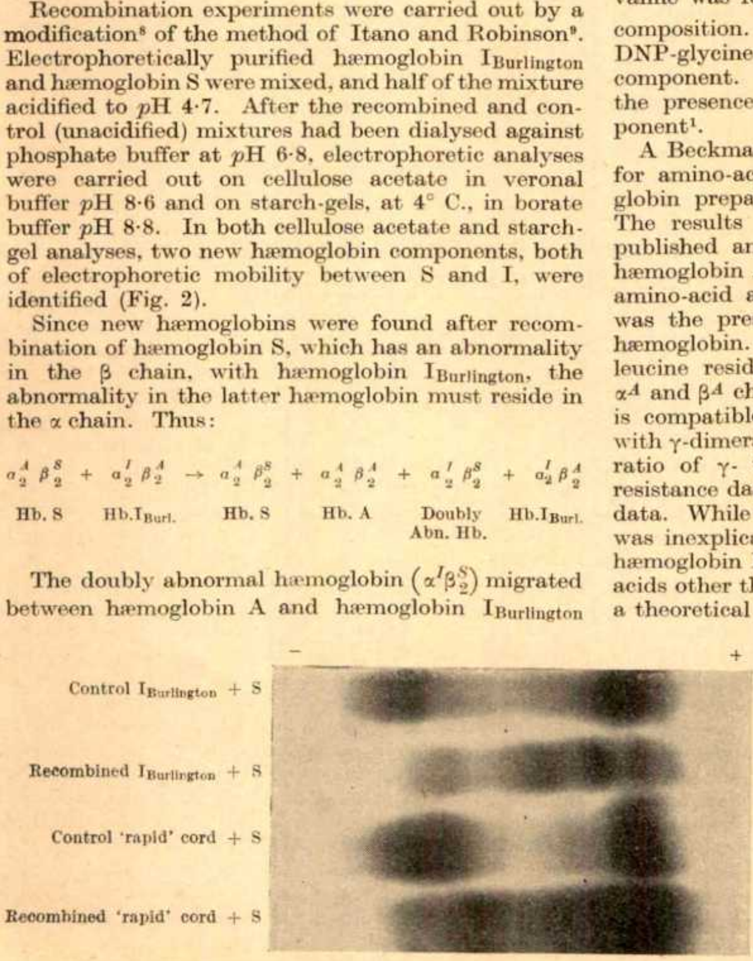

Fig. 2. Vertical starch-gel electrophoresis of hæmoglobin recombination studies in borate buffer pH 8·8 at 4° C. Migration time 16 hr., benzidine stain. In recombined hæmoglobin $\text{I}_{\text{Burlington}}$ + S, components had following mobilities (left to right): S, A, double abnormal, I. In recombined 'rapid' cord + S, the components are not designated by formulæ

Biochemical studies of fœtal hæmoglobin have provided evidence for the identity of the α-chains of hæmoglobins A and F. The differences between fœtal and adult hæmoglobin apparently reside in the remaining polypeptide chain: the β-chains of hæmoglobin A begin to replace the γ-chains of hæmoglobin F before birth. Thus, while β-chain abnormalities are grossly evident only some months after birth, an α-chain abnormality should be manifested by an abnormal fœtal hæmoglobin at birth. In the present study an infant, heterozygous for hæmoglobin I^a, had two normal hæmoglobins: F $(\alpha_2^A\gamma_2^F)$ and A

$(\alpha_2^A\beta_2^A)$, and two abnormal hæmoglobins: fœtal I $(\alpha_2^I\gamma_2^F)$ and adult I $(\alpha_2^I\beta_2^A)$, at birth. Five months later, the hæmoglobin of C. S. still contained the same amount (±20 per cent) of a rapid abnormal component. At this time, however, the electrophoretic mobility of this component was apparently the same as that of hæmoglobin $\text{I}_{\text{Burlington}}$, and the alkali resistance of the total hæmoglobin and of its components had declined from 70 to 12 per cent.

An example of another fœtal hæmoglobin with an α-chain abnormality $(\alpha_2^D\gamma_2^F)$ has been described by Minnich *et al.*[13].

These abnormal fœtal hæmoglobins provide biological evidence for the identity of the α-chains of hæmoglobins F and A. The change from fœtal to adult hæmoglobin is apparently the result of a switch over in synthesis from γ-chains to β-chains, which then combine with the normal or abnormal α-chains.

We thank Prof. Mary Jane Gray, who initiated the fœtal hæmoglobin survey in Burlington, Mr. Carl Franzblau for supervision of the amino-acid analyses, and Prof. V. Minnich for allowing us to read her unpublished manuscript.

MOLECULAR WEIGHT OF RABBIT GAMMA-GLOBULIN

By DR. K. A. CAMMACK

Microbiological Research Establishment, Porton, Wilts.

ALTHOUGH rabbit γ-globulin is heterogeneous in electrophoretic behaviour, sedimentation velocity boundary spreading experiments indicate that the homogeneity in molecular size and shape is comparable with that for many other proteins of consistent and reproducible physical properties. Thus, though it may be anticipated that different fractionation procedures may result in samples of varying mean mobility, it is surprising to find such a wide range of molecular weight values (150,000–188,000) quoted[1] for different fractions studied in the past. Porter[1] has suggested that this variation arises from errors in the determination of S and D values inserted in the Svedberg equation, $M = RTS/D(1 - \bar{v}\rho)$. One theory of antibody formation due to Pauling[2] postulates that though an antigen may modify the shape of the γ-globulin molecule it can in no way alter its molecular weight, since it cannot interfere in the primary synthesis of polypeptide. It may therefore be of some importance to determine accurate molecular weights for γ-globulin and antibody.

Fractions examined in this work were isolated from batches of normal rabbit serum and a rabbit anti-ovalbumin serum obtained by short-term immunization over a 4-week period. The Nichol and Deutsch[3] low-temperature ethanol scheme was used for isolating the γ-globulin; the globulin was re-precipitated with 20 per cent w/w ethanol at – 5° under the conditions of Nichol and Deutsch to remove traces of serum albumin. Additionally, normal sera were fractionated by precipitation with sodium sulphate[4] and by chromatography on a DEAE cellulose (Whatman floc) column[5]. The partially immune globulin (batch 6/7) contained about 40 per cent antibody, determined under conditions for maximum precipitation with ovalbumin, and this agreed quite well with the figure deduced from combined precipitin and electrophoretic analyses of the original antiserum, providing good evidence that the protein had not been denatured by ethanol.

Sedimentation measurements were carried out in a Spinco model *E* ultracentrifuge, and rotor temperature was recorded at frequent intervals during the run. Diffusion measurements were made by the Gouy interferometric method[6] in an Ogston diffusion cell of optical depth 1·774 cm. All samples were dialysed against phosphate saline buffer (pH 7·00, I 0·045 sodium phosphates + I 0·125 sodium chloride). Physical homogeneity in the ultracentrifuge was tested by the value of the ratio $(\Delta n)uc/(\Delta n)dr$, where $(\Delta n)uc$ is the refractive increment across a velocity boundary corrected for sectorial dilution and $(\Delta n)dr$ is a direct measurement in the differential refractometer using dialysed solution and the buffer.

Each fraction gave a single velocity boundary in the ultracentrifuge. The $(\Delta n)uc/(\Delta n)dr$ ratios based on the initial sedimentation diagram photographed about 30 min. after attaining a maximum speed of 59,780 rev./min. were 0·94–0·99. Measurements on later photographs, taken at 16-min. intervals, revealed a steady decrease to values which were 6–10 per cent below the initial figures by the time the boundary had reached the bottom of the cell. Apparently minor components did resolve although the location of the base-line for the boundary is often difficult and introduces errors in $(\Delta n)uc$. Less drift was found in a double-sector cell where the base-line is accurately recorded under the same run conditions (Fig. 1), but as this cell is restricted to a centrifugal field of 100,000g compared with 250,000g in a standard cell the resolving power of the method is reduced. Electrophoresis in veronal buffer (pH 8·6, I 0·10 sodium veronal) showed boundaries quite typical of γ-globulin and no evidence for other serum com-

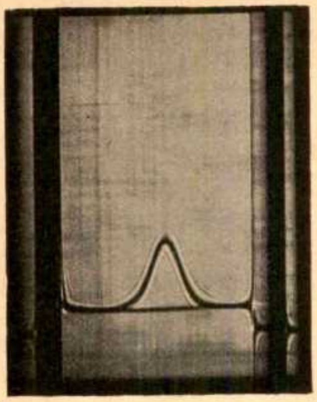

Fig. 1. Sedimentation diagram from the 'Spinco' model *E* ultracentrifuge. Material: rabbit γ-globulin (batch 6/7) isolated from anti-ovalbumin serum by fractional precipitation with ethanol. Solvent: *p*H 7·0, *I* 0·045 sodium phosphates + *I* 0·125 sodium chloride. Speed 37,020 rev./min. Sedimentation from right to left in double-sector cell. Initial $c = 0{\cdot}93$ per cent w/v. Phase plate angle 60°. Exposure 148 min. from reaching full speed

ponents. The electrophoretic mobilities showed variations from batch to batch ($-$ 1·50 to $-$ 1·68) × 10^{-5} cm.^{2} sec.$^{-1}$ V.$^{-1}$. After dialysis against unbuffered saline (*I* 0·145 sodium chloride) material not required for immediate use was stored at $-$ 20°. Six months later, after dialysing against neutral phosphate-saline, about 5 per cent of a new component, $S_{20,w}$ 9·0 was observed, which is probably a dimer of the normal molecule[7].

Sedimentation and diffusion coefficients for rabbit γ-globulins are plotted as a function of protein concentration in Figs. 2 and 3. The regression line for sedimentation data on partially immune γ-globulin (batch 6/7) may be expressed as $S_{20,w} = 6{\cdot}73 - 0{\cdot}236\ (\pm 0{\cdot}014)c$. Except for two diffusion results on the 'inert' γ-globulin fraction to be discussed later, all the diffusion data were combined in a common regression line given by $D_{20,w} = 4{\cdot}66 - 1{\cdot}21\ c$. From data extrapolated to zero concentration and a partial specific volume of $\bar{v} = 0{\cdot}745$, the molecular weight may be calculated as 137,000. The results for normal globulins isolated by various methods show that their molecular weights do not deviate markedly from this value. If concentration dependence of *S* and *D* is ignored the molecular weight calculated for 1 per cent protein is 179,100. An Archibald run performed on a 0·96 per cent solution of batch 6/7 gave a mean molecular weight of 172,700, again a high result but in fair agreement with an Archibald molecular weight of 187,600 ($\bar{v} = 0{\cdot}735$) determined quite independently by Charlwood[8] under similar conditions on a normal rabbit γ-globulin obtained by the sodium sulphate method. As expected, Archibald values for lower protein concentrations approached the true molecular weight, but the rapid deterioration in precision scarcely justified an extrapolation to zero concentration. The upper and lower figures (137,300–179,100) for the range of concentration examined are therefore comparable with results in the literature (150,000–188,000) and strongly suggest that the variation is due mainly to neglect of concentration-dependent diffusion.

A frictional ratio, $f/f_0 = 1{\cdot}34$, calculated from the revised figures is not much lower than earlier estimates, and, depending on what assumptions one may care to make regarding the effect of solvation on molecular configuration, various hydrodynamic models could be suggested which simulate the sedimentation and diffusion behaviour of γ-globulin, but without precise viscosity data the "effective hydrodynamic volume", as defined by Scheraga and Mandelkern[9], cannot be calculated.

An attempt to differentiate 'inert' from antibody globulin was made by first precipitating antibody from the 'partially immune' anti-ovalbumin fraction, batch 6/7, under conditions giving maximum precipitation of antibody, centrifuging off the specific precipitate, and then examining the 'inert' globulin left in the supernatant (cf. Porter[10]). Soluble antigen–antibody complexes may contaminate the 'inert' fraction and in detecting their presence the constancy of $(\Delta n)uc/(\Delta n)dr$ is very important. Previous measurements on the parent globulin, consisting of roughly equal proportions of 'inert' and antibody molecules, showed a drift of 0·99–0·94 during sedimentation, while the 'inert' globulin derived from the mixture showed an increasing drift from 0·97 to 0·84. This result indicated that not more than 5 per cent of the 'inert' fraction was in the form of soluble complexes with $S_{20,w} > 7{\cdot}0$. The slope of the regression line, $S_{20,w} = 6{\cdot}82 - 0{\cdot}389\ (\pm\ 0{\cdot}0138)c$, and $S^0_{20,w} = 6{\cdot}82$ (Fig. 2), were both significantly

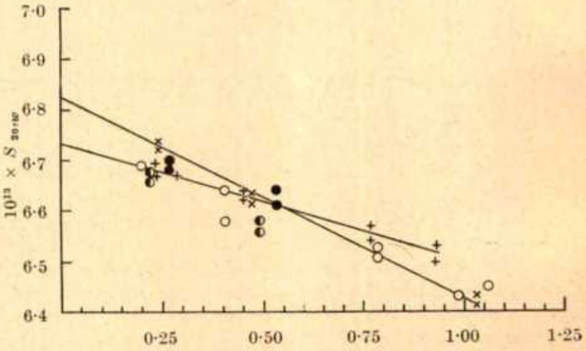

Fig. 2. Plots of $S_{20,w}$ against protein concentration for various rabbit γ-globulin fractions. +, batch 6/7, isolated from anti-ovalbumin serum by the ethanol method; ×, 'inert' fraction derived from batch 6/7. Solvent: *p*H 7·0, *I* 0·045 sodium phosphates + *I* 0·125 sodium chloride

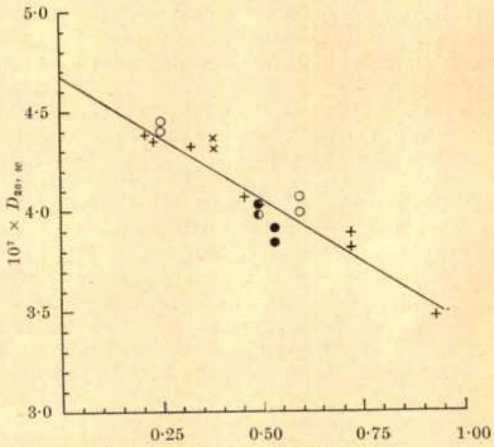

Fig. 3. Plots of $D_{20,w}$ against protein concentration for various rabbit γ-globulins using the same symbols as those in Fig. 2. The regression line is drawn for the pooled data omitting the 'inert' fraction derived from batch 6/7. Solvent: *p*H 7·0, *I* 0·045 sodium phosphates + *I* 0·125 sodium chloride

greater than those obtained for the original mixture. Nevertheless, these results, combined with a mean $D_{20,w} = 4\cdot33 \times 10^{-7}$ cm.^{2}sec.$^{-1}$ determined at $c = 0\cdot355$ per cent (Fig. 3), show that the molecular weights of both types of globulin did not differ by more than 3 per cent.

The results thus show that the molecular weights of various normal and one partially immune globulin differ by amounts which are comparable with present experimental error, and suggest that further precise work to test the validity of the Pauling theory may be justified. In particular, it would be of interest to confirm and to interpret the different sedimentation concentration dependencies which this work suggests may exist between 'inert' and antibody γ-globulins.

DEVELOPMENT OF MOUSE EMBRYOS IN ORGAN CULTURES OF FALLOPIAN TUBES ON A CHEMICALLY DEFINED MEDIUM

By PROF. J. D. BIGGERS, DR. R. B. L. GWATKIN and DR. R. L. BRINSTER
King Ranch Laboratory of Reproductive Physiology, University of Pennsylvania, Philadelphia 4

WHITTEN[1] demonstrated that 8-cell mouse embryos will develop into blastocysts when cultivated in a balanced salt solution containing glucose and bovine plasma albumin. Later, McLaren and Biggers[2] showed that blastocysts produced in this way would develop into normal mice after transfer to uterine foster mothers, and this fact has been amply confirmed and exploited by Tarkowski[3] for the production of mammalian chimeras. So far, however, no one has devised a medium which will regularly allow development *in vitro* of mouse embryos through the first three cleavage divisions.

As an indirect approach to this problem we have cultured mouse Fallopian tubes *in vitro* on a completely chemically defined medium, and have shown that mouse embryos will develop within these tubes from the uncleaved zygote through to advanced blastocyst stages. Furthermore, other preliminary experiments suggest that blastocysts produced in this way can develop within uterine foster mothers into normal embryos. Our results are summarized in this article.

The Fallopian tubes from super-ovulated, mated, 8–9-week-old female mice, from the randomly bred Swiss strain, were cultured on medium *BGJb* containing 5 mgm. glucose per ml. (Table 1). This medium is chemically defined, and was originally used in investigations of the growth and differentiation of embryonic cartilaginous long bones *in vitro*[4]. The vessel, used for the culture of one Fallopian tube, consisted of a Petri dish (6 cm. diam.) containing a 2 cm. × 2 cm. stainless steel grid, 3 mm. high. A disk of tea-bag paper (Grade No. 10–V–7–1/4; C. H. Dexter and Sons, Inc., Windsor Locks, Connecticut) was placed on the grid.

10 ml. medium were placed in each dish. Contact of the medium with the wire mesh and paper was maintained by surface tension, so that the explant was always exactly at the interface, ensuring, thereby, an adequate supply of oxygen to the tissues. The two Fallopian tubes were removed from each mouse by cutting through the ovarian bursi, as close to the ovaries as possible, and through the utero-tubal junctions. Each Fallopian tube was then uncoiled by carefully clipping the mesentery holding the coils together, and stretched out by gently drawing the tube across the paper. The dishes were incubated at 37° C. in a chamber through which humidified 5 per cent carbon dioxide in air continuously flowed.

The mice were superovulated by the injection at 12 noon of 5 I.U. pregnant mare serum gonadotrophin (Gestyl, Organon), followed 48 hr. later by 3 I.U. human chorionic gonadotrophin ('Pregnyl', Organon). Fertile males were placed with the females at the time of the second injection. This treatment results in ovulation and mating about 12 hr. after the second injection. Females with vaginal plugs were killed 10–12 hr. later, that is, 12–14 hr. before the expected time of the first cleavage division[5]. In several experiments we have always found that this schedule yields unsegmented ova at the top of the Fallopian tubes.

Fifty-four Fallopian tubes were cultured for either 3 or 4 days, and their contents examined. The results are summarized in Table 2. Forty-three tubes (80

per cent) contained developing eggs, and 159 of the 215 eggs (74 per cent) examined had developed at least into morulæ. However, the tubes examined on the third day contained only morulæ, with the exception of one early blastocyst, while the tubes examined on the fourth day contained a predominant number of blastocysts. According to Lewis and Wright[6] morulæs develop into blastocysts *in vivo* on the third to fourth day after fertilization, so the rate of development was unaffected by the conditions of culture. A typical living blastocyst produced in this way is shown in Fig. 1. A well-defined inner cell mass and a large central cavity has developed.

Table 2. DEVELOPMENT OF EARLY MOUSE EMBRYOS WITHIN FALLOPIAN TUBES MAINTAINED IN ORGAN CULTURE FOR 3 OR 4 DAYS ON MEDIUM *BGJb*

4	25	21	106	14	69

Fig. 2 shows a section through a typical Fallopian tube at the time of explantation, containing two ova embedded in a mass of corona cells. Fig. 3 shows a section through a Fallopian tube which had been cultured for four days, containing a well-developed blastocyst. It is clear that the structure of the Fallopian tube is preserved throughout the period of cultivation. The cilia of the epithelial cells lining the Fallopian tube continued to beat throughout the culture period in almost all explants, causing the movement of particles within the lumen of the tube. During the first two days after explantation no muscular movement occurred in the tubes. On the third day, however, segmental movements occurred in a few explants and on the fourth day nearly all explants were undergoing similar movements. The significance of the onset of motility after an initial quiescent period is unknown. However, it may have no physiological significance, since muscle cells under adverse conditions may discharge action potentials spontaneously. If these potentials occur in the Fallopian tubes, therefore, the contractions may merely indicate early signs of degeneration of the cultures.

Several blastocysts which had developed in organ cultures of Fallopian tubes were transplanted into

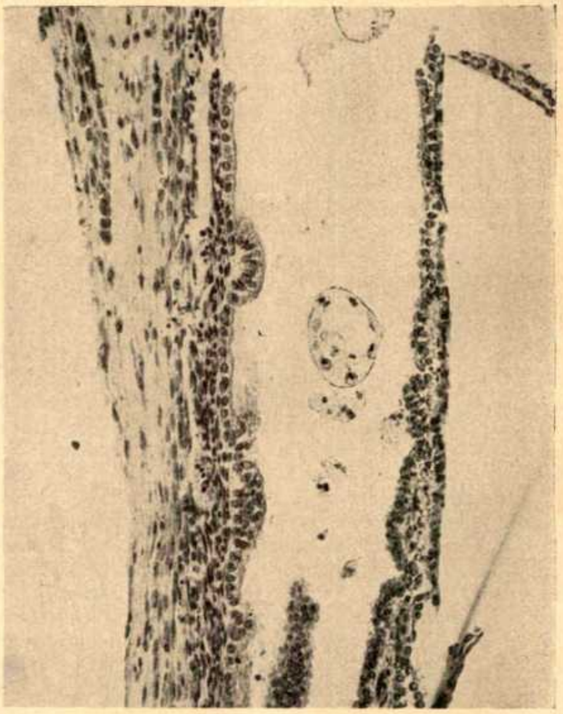

Fig. 3. Fallopian tube after 4 days cultivation on medium *BGJb*, containing a well-developed blastocyst (× *c*. 137)

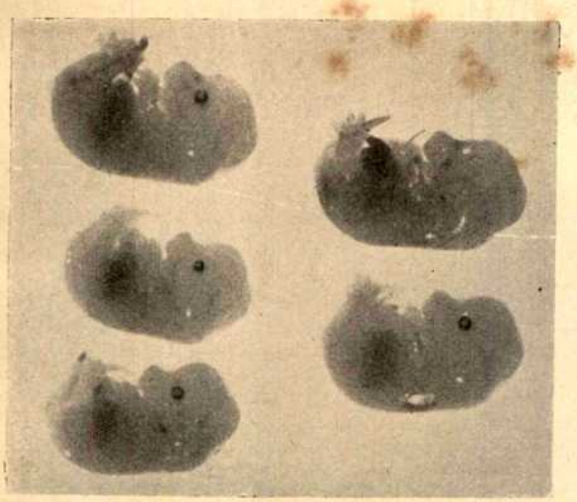

Fig. 4. Seventeen-day-old litter from a *C*57 uterine foster mother, containing 4 native embryos and 1 alien (cultured) embryo

the uterus of inbred *C*57 black mice which had been superovulated and mated to *C*57 males three days previously. On the seventeenth day of pregnancy the embryos inside the uterine foster mothers were examined for eye colour. Fig. 4 shows a litter of 5 mice in which 4 have black eyes (native fœtuses) and one is colourless (cultured fœtus). Although this result is very preliminary, it suggests strongly that the conditions of culture have little adverse affect on the early embryos. Further work on this problem is in progress.

Although the results in Table 2 shows that the ovary is not essential for the development of early mouse embryos in cultures of Fallopian tubes, we also did some experiments in which the ovary was left attached to the Fallopian tube. The presence of the ovary had no obvious influence on the development of the embryos.

The results described in this article show clearly that normal mouse embryos develop *in vitro* within Fallopian tubes maintained on a completely chemically defined medium. Such media do not allow the development of early stages outside the Fallopian tube, even if the media are supplemented with natural body fluids such as serum.

There are two possible explanations of these results. First, the Fallopian tubes may provide material which is essential for the first three cleavage divisions to occur. Secondly, the secretions of the Fallopian tube may exert a protective action on the embryos up to the 8-celled stage.

The results also demonstrate that early embryonic development inside the Fallopian tube does not depend on a continual supply of some hormone. If a hormone is required, then the amount present in the Fallopian tube at the time of explanation is sufficient for the 4-day period of development *in vitro*.

INTERRELATIONS BETWEEN DIFFERENT MECHANISMS OF RELEASE OF BIOLOGICALLY ACTIVE PEPTIDES FROM BLOOD PLASMA

By J. MARGOLIS and ELIZABETH A. BISHOP

Children's Medical Research Foundation, Royal Alexandra Hospital for Children, Camperdown, Sydney

IN recent years increasing attention has been given to a possible physiological role of a highly potent vasodilator substance which is released from blood plasma by various agents. According to the experimental system used, it has been called kallidin, bradykinin, pain-producing substance and plasma kinin[1–5]. All these names may well refer to the same substance, probably a nonapeptide[6], the formation of which presumably involves a proteolytic mechanism. Yet the process may be initiated by agents as varied as acetone, foreign surface, dilution, trypsin, snake venoms, saliva, urine, versene and ε-amino-caproic acid (EACA)[1–5,7,8]. As has been shown elsewhere[5,9], foreign surface acts by adsorbing and activating the Hageman factor (*HF*); this in turn activates a 'component *A*', which together with another factor ('component *B*') brings about the release of plasma kinin. In addition, plasma contains powerful inactivators which destroy the active products almost as soon as they are formed.

In order to find possible relations between the above and some of the other activation mechanisms we prepared human 'intact' plasma and its derivatives which were deficient in one or more of the essential precursors (*HF*, *A* and *B*)[9] and subjected them to various activation procedures. These samples were then tested on rat uteri by methods previously described[5,9], for plasma kinin and for the capacity to release kinin from intact substrate plasma. The latter ('indirect test') is a measure of activated component *A* (ac–*A*) probably identical with plasma kallikrein[1].

A summary of the findings as well as the probable equivalence of our terminology with that of the kallikrein–kallidin system is given in Table 1. In agreement with other authors[8,10,11], we have found that the factors required for the activation of plasma by surfaces are also necessary for the release of kinin by acetone, chloroform, versene and EACA (Table 1, tests 1, 2, 3), while urine and saliva do not require these factors but appear to act on the substrate (kallidinogen) directly. Acetone has a two-fold effect on plasma: it slowly activates *HF* and it destroys the inactivator of ac–*A*. Normally, ac–*A*

Table 1. Activation of Plasma and Derivatives by Various Agents

Test	Activator		Product tested for	Untreated	Heated 57° C. 30 min.	Heated 60° C. 30 min.	Deficient in *HF*	Depleted of comp. *A* and *B*	Depleted of comp. *B*

decays with extraordinary speed (half-life at 20° C. is 1–2 min.) but in the presence of acetone it is stable for days and so accumulates as the reaction progresses[12]. However, acetone has little, if any, effect on the plasma peptidase, which continues to destroy any kinin that is released (cf. test 2*a*). Versene arrests the decay of kinin, probably by immobilizing a metal (? zinc) on which the peptidase is dependent[12]. Therefore, when both acetone and versene are added to plasma, not only ac–*A* but also plasma kinin is preserved from destruction. Under these conditions we find that kinin can also be detected in plasma depleted of component *B* (test 4*a*). Webster and Ratnoff[11] raised the question whether plasma kallikrein could liberate kallidin (kinin) in the absence of component *B*. The foregoing results show that this can, indeed, take place but the process is so slow that normally it cannot outstrip the destruction of kinin. Thus, component *B* may be regarded primarily as an accelerator, but it becomes an essential factor under conditions when destruction of plasma kinin proceeds apace with its production as, for example, with glass beads.

EACA also prevents the decay of kinin in plasma, though not as efficiently as versene[12]. We were unable to find any evidence that EACA has any direct activating effect on the kinin-releasing system. As in the case of versene, the slow and variable appearance of plasma kinin under the influence of EACA[8] is probably simply due to cumulative effects of such marginal factors as contact with siliconed or plastic surfaces.

Up to now 'glandular' kallikreins like saliva could be regarded as acting quite independently of the components involved in surface or acetone activation. Both systems, however, converge on the same final substrate (kallidinogen). This is shown in the experiment in Fig. 1, which may be regarded as a 'kallidinogen consumption test'. Here plasma and derivatives were incubated with 20 per cent v/v acetone for 16–48 hr. and then tested for ac–*A* (kallikrein) (Fig. 1*a*) and also for the capacity to release kallidin with saliva (*b*). As could be expected, kallikrein was produced only in those samples which contained both *HF* and component *A*. This is shown most clearly in tracings 3 and 4 (see also Table 1, test 6). In tracing 3, in which *HF*-deficient and *A*-depleted plasmas were mixed first and then incubated with acetone, kallikrein was formed as in normal plasma; in test 4, where these samples were incubated with acetone separately and mixed immediately before addition to substrate plasma, kallikrein formation did not occur.

Activation with saliva gave exactly opposite results. All the samples which could be activated with acetone (tests 1, 3, 6, 7) no longer released kallidin when saliva was added next day, whereas those in which the conditions for the minimum reacting system (*HF*, component *A* and acetone) were not fulfilled (tests 2, 4, 5, 8) yielded normal amounts of kallidin with saliva. Similar observations were recorded using urine or trypsin instead of saliva. We regard these results as evidence that plasma kallikrein utilizes the same substrate as the 'glandular' kallikreins and, implicitly, as a further support for the hypothesis originally formulated to deal with plasma/surface reactions[9,13]. This concept can now be expanded to include some of the other kinin-releasing agents and also to indicate the role of inhibitors in the economy of these reactions.

It is true that in identifying such terms as, for example, component *A* and kallikreinogen there is a chance

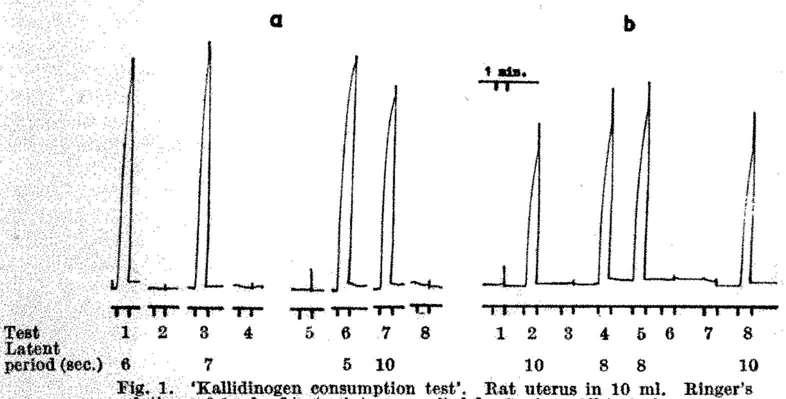

Fig. 1. 'Kallidinogen consumption test'. Rat uterus in 10 ml. Ringer's solution. 0·1 ml. of test mixtures applied for 1 min. All test plasmas were incubated with 20 per cent v/v of acetone for 24 hr. and tested for ac-*A* (kallikrein) by the 'indirect test' (Refs. 5 and 9) (*a*) and for formation of kinin (kallidin) after incubation with 1 part of saliva in 6 of plasma for 4 min. (*b*) *Test plasmas*: 1 and 6, normal; 2, depleted of comp. *A* and *B*; 5, deficient in *HF*; 3, plasmas (2) and (5) mixed first then incubated with acetone; 4, (2) and (5) incubated with acetone separately and mixed just before testing; 7, depleted of comp. *B*; 8, heated to 60° C. for 30 min. Note that in (*b*) the results are exactly opposite to those in (*a*)

that each may prove to be a complex system and not a single substance. None the less, we consider that at the present state of knowledge there is a need for a unifying concept even at the peril of some over-simplification.

REVERSIBLE INACTIVATION OF BLOOD-GROUP A AND B SUBSTANCES FROM RED CELLS

By Dr. J. KOŚCIELAK*

Lister Institute of Preventive Medicine, London, S.W.1

THE chemical nature of ABO blood-group substances from red cells still remains an unsolved problem, although several claims have been made that these substances are glycolipids composed of galactose, glucose, amino sugars, sphingosine and fatty acids[1–4]. The main difficulty in assessing the nature of these materials was the low blood-group activity of the preparations obtained so far which never exceeded more than 20 per cent of the blood-group active material isolated from human secretions. None of the preparations of red-cell substances can be regarded as homogeneous; even 'globoside', which was claimed to be a pure homogeneous substance[1], was later separated into several fractions by means of chromatography on silicic acid columns[5]. One of the most potent preparations of substance A obtained from red cells was that isolated by Kościelak and Zakrzewski[3]. This material was, however, a mixture of at least two compounds containing hexosamine[6]. Subsequent attempts to purify this material further yielded some unexpected results. Although it could be readily separated into two main fractions by means of starch-column and paper chromatography in butanol ethanol–water solvent, the hæmagglutination activity of the separated fractions was always 1–10 per cent only of the value of the original material[7]. Essentially the same results were obtained using chromatography on silicic acid columns. The hæmagglutination inhibition activity of the separated components amounted only to 1 per cent of the activity of the material before separation. Thus, the original substance behaved like a complex, since more than one component was required to exert full activity.

In the course of the present investigation, the blood-group active *A* material from red cells was isolated by a technique similar to one described previously[3,6]: the main difference was that instead of extracting whole cells with ethanol, stromata were used as a source of blood-group substance. Red cells were hæmolysed with 10 vol. of tap water; solid carbon dioxide was added together with a few ml. of capryl alcohol to prevent excessive foaming and the hæmolysate was centrifuged in a Sharples centrifuge. Absolute ethanol was then added to the stroma paste to give 83 per cent ethanol concentration, and the resulting stroma suspension allowed to stand at room temperature for a few days with occasional shaking. The ethanol extract was then filtered off and cooled to −8° when a white precipitate formed. The precipitate was collected by centrifugation at −8°, washed with one-tenth of its volume of cold 83 per cent ethanol then with a large volume of acetone and finally dried *in vacuo*. This 'crude' A substance had the same general composition as one obtained by extraction of whole cells. Its solubility properties were, however, somewhat different, and it could be largely dissolved by prolonged extraction with petroleum ether, whereas material from whole cells was practically insoluble in this solvent. The crude substance after brief extraction with acetone followed by ethyl ether was washed twice with petroleum ether and then subjected to hot methanol extraction and the material soluble in methanol (precipitate *M*) chromatographed on a cellulose column[3,6].

In contrast to the results with material isolated from intact cells, the decrease of activity was observed after separation of this precipitate *M* into fractions IA and IIA on a cellulose column (Table 1). The residual blood-group activity after separation was confined to fraction IIA. However, when these results were checked by means of quantitative precipitation test using anti-A rabbit serum it was found that the activity of fraction IIA had increased four times compared with the activity of precipitate *M*, whereas fraction IA was inactive in both tests. Later, an attempt was made to restore hæmagglutination activity of the isolated fractions by adding them together. This recombination experiment was simply done by dissolving fraction IA and fraction IIA in proportions of 3 : 1 in a mixture of chloroform–methanol and evaporating the solution to dryness *in vacuo*. The hæmagglutination activity was fully restored under these conditions (Table 2). This phenomenon is not due to some physicochemical effect of fraction IA on the red-cell membrane in the test system and true complex formation must occur as is illustrated by an experiment in which fraction IA and IIA were mixed together in aqueous solutions. Under these conditions no increase of activity was observed and the resulting activity of the mixture was due solely to its content of fraction IIA. Further confirmation of the formation of a complex between the two fractions is to be found in their solubility properties. Whereas precipitate *M* and fraction IIA are water-soluble, fraction IA is only slightly soluble in water and forms a heavy colloidal suspension. The possibility that fraction I contains some blood-group activity which is not detected owing to its

Table 1. PROPERTIES OF THE FRACTIONS OBTAINED FROM A CELLULOSE COLUMN

	Precipitate *M*	Fraction IA	Fraction IIA
Hexosamine (per cent)	5·0	2·8	9·2
Reducing sugar (per cent)	20·5	17·2	42·7
Sialic acid (per cent)	1·3	0·6	4·1
Nitrogen (per cent)	2·8	2·6	1·9
Component sugars	glucose, galactose, glucosamine, galactosamine	glucose, galactose, galactosamine	glucose, galactose, glucosamine, galactosamine, traces of fucose
A activity in hæmagglutination inhibition test (dilution)	$2 \cdot 5 \times 10^{3}$	$< 2 \cdot 5 \times 10^{2}$	$1 \cdot 25 \times 10^{4}$
A activity in quantitative precipitation test (per cent of the antibody nitrogen precipitated by the standard cyst A substance)	15	nil	60

Table 2. RECOMBINATION EXPERIMENTS

Precipitate *MA*	20
Fraction IA	less than 0·005
Fraction IIA	1
Fraction IA + fraction IIA	20
Fraction IA + fraction IIA (recombined in aqueous solution)	0·25
Fraction IB + fraction IIA	20
Sphingomyelin from pig spleen + fraction IIA	1
Lecithin from pig kidney + fraction IIA	1

Activities (hæmagglutination inhibition) are expressed on the weight basis as the percentage of the standard preparation of cyst A substance 401.

insolubility in water was, however, excluded by an experiment with fraction IB isolated by essentially the same technique from B cells. In the case of substance B, decrease of hæmagglutination inhibition activity was also observed after separation on cellulose columns, and the activity could be restored by a recombination of the two fractions in organic solvent solution. Fraction IB, which was completely inactive in hæmagglutination tests, was then joined to fraction IIA. The full restoration of A activity occurred and the material did not exhibit any B activity. Obviously, fraction I has only carrier properties.

Some insight as to the nature of the phenomenon described is given by the attempt to restore blood-group activity of fraction II by combining it with simple lipids such as lecithin and sphingomyelin (kindly supplied by Dr. G. M. Gray). Some increase of activity (4 times, based on the amount of fraction IIA present) was observed with both these phosphatides, and the results suggest that the full blood-group activity of red-cell substances can be exerted only by combination with some 'carrier' material which produces possibly the favourable molecular shape and proper distance between chemical groupings of native blood-group substance which allows combination with antibody molecules. The linkage between blood-group substance and the 'carrier' must be a weak one and involves possibly the interaction between a sphingosine-fatty acid residue of the blood-group substance with large, predominantly lipid, micelles of the 'carrier', whereas hydrophilic carbohydrate groups of the active substance project outwards being available for combination with the antibody molecules. This complex formation is reminiscent of the results obtained with Shiga lipoprotein, which also functioned as a 'carrier' for blood-group substances isolated from human secretions, and thus brought about the enhancement of their antigenic properties[8]. The apparent discrepancy between hæmagglutination inhibition activity and precipitation activity of fraction II in the present study can be explained on the basis of qualitative difference between these tests. The hæmagglutination inhibition test is essentially a competitive one in which the inhibitor competes for antibody molecules with the native antigen on the red-cell surface. The firmness of this reaction depends on the correct molecular size and shape of the antigen. In precipitation tests only antigen and antibody are present in the reaction mixture and combination may occur even with an antigen more distantly related spatially towards the antibody.

The above results may explain the failure to obtain highly active and homogeneous blood-group ABH substances from red cells as well as antigens from other cells. They stress that caution is required in drawing conclusions from experiments involving treatment of intact cells or impure mixtures of biologically active substances with enzymes or 'specific' chemical reagents in order to ascertain the true chemical nature of the structures responsible for the biological activity under investigation. Any loss of activity which might occur under these conditions can be the result of a change of the specific spatial pattern of the receptor residues on the cell surface without any destruction of the receptor itself.

I thank Prof. W. T. J. Morgan for his interest and advice throughout this investigation.

PERSISTENCE AND STABILITY OF SPECIES-SPECIFIC HÆMAGGLUTINOGENS IN CULTIVATED MAMMALIAN CELLS

By K. GERHARD BRAND

Department of Microbiology, University of Minnesota

CULTIVATED mammalian cells when injected into laboratory animals induce hæmagglutinins[1] which react species-specifically[2,3]. This reaction has been used for classification of cultivated mammalian cells according to species[4]. Results have usually confirmed stated species origins of cell strains except for many 'transformed' cell strains, 17 of which were found to be of either human or mouse species although they were reportedly derived from other species[5]. At least two explanations have been suggested for the occurrence of cell transformation: (*a*) a genetic process involving mutation and selection under certain cell culture conditions[6]; (*b*) contamination and overgrowth of original cultures with cells of fast-growing established laboratory strains. If the former concept were true, lability and variability of cellular species-specificity should easily be demonstrable under controlled experimental conditions since cell transformation appeared a frequent event under 'normal' laboratory conditions. Experiments were therefore performed to examine the degree of stability and persistence of species-specific hæmagglutinogens in cultivated mammalian cells. Such experiments were of particular interest after it was found by Weiler[7] and Högman[8] that organ and blood group-specific cell antigens disappear during early stages of cell cultivation. Also these investigations were considered useful with regard to general classification of animal cells, since only if species antigens were shown to be stable could they serve as permanent labels of cells in continuous culture.

HeLa cells, cottontail rabbit epithelial cells, mouse *L* cells and cell lines reported to be variants of *L* cells[6,9,10] such as *MCN*, Lung To, *AMK*, *U*-12 and *FS* were used.

The basic procedures of cell cultivation using yeast extract medium have been described elsewhere[3,6]. Three sub-lines of HeLa were investigated, the culture media of which differed in serum supplements. *HuS*–HeLa had been kept for about 60 passages on yeast extract medium with 20 per cent human serum, *HoS*–HeLa for 75 passages on 20 per cent horse serum, *CaS*–HeLa for about 50 passages on 20 per cent calf serum. The cottontail rabbit epithelial cell strain established in this department on 20 per cent rabbit serum medium was adapted to and cultivated for about 15 passages on 20 per cent calf serum medium. The parent *L*-strain had been kept in this department for about 150 passages since 1951 on media with horse serum supplement. The other *L*-cell variants were received only shortly before use in these experiments[5]. They were carried through a few passages on 20 per cent horse serum (*MCN*, Lung To) or 20 per cent calf serum (*AMK*, *U*-12, *FS*).

Monolayers of *CaS*–HeLa cells were washed with buffered saline, mechanically dispersed and counted in a blood cell counting chamber. Aliquots were treated in the following ways: (*a*) heating for 5 min. at 45° C.; (*b*) heating for 5 min. at 80° C.; (*c*) 50 cycles of freezing (– 70° C.) and thawing (+37° C.); (*d*) enzymatic treatment of cell surfaces for 30 min. with 0·2 per cent trypsin; (*e*) no treatment (control cells). Four culture bottles of that same batch were X-irradiated with a total of 1,300 r. Cells of two culture bottles were washed, dispersed and counted. The remaining two cell cultures were maintained in yeast extract medium containing 20 per cent calf serum for 14 more days before the cells were prepared in the same way.

According to the original procedure[3] for demonstration of species-specific cellular hæmagglutinogens cultivated cells were washed free of medium, disrupted in phosphate-buffered saline (*p*H 7·2), and injected into guinea pigs. Pre- and post-immunization serums were titrated for hæmagglutinins against erythrocytes of various species.

In experiments with the above treated HeLa cells, cell-debris prepared from 10^2, 10^3 and 10^4 cells contained in 0·5 ml. were each injected intramuscularly into two guinea pigs. The immunization response of animals was determined in two ways: (*a*) Sera were checked two, three and four weeks after initial injection. If positive, this was considered a direct response; (*b*) if negative, animals received a hyperimmunization injection of 100,000 untreated HeLa cells intraperitoneally. Serum samples were taken on the fifth, tenth and fourteenth day after hyperimmunization injections. Immediate development of high-titred hæmagglutinins by the fifth–tenth day was considered to indicate preceding sensitization of animals from initial injections.

Table 1. INDUCTION OF SPECIES-SPECIFIC HÆMAGGLUTININS IN GUINEA PIGS BY CELLS OF VARIOUS SUB-LINES OF STRAINS HELA, *CRE*, AND *L*

Antisera against	Passage-number of cell lines in this laboratory	Increase of hæmagglutinins (by number of two-fold dilution steps) for erythrocytes from: Man	Monkey	Rabbit	Mouse	Others*

In agreement with Westwood's[6] unsuccessful attempts to transmit a hypothetical cell-transforming principle, I was unable to demonstrate any change of species-specific antigenicity in human HeLa, cottontail rabbit epithelial and mouse *L*-cell cultures adapted to and cultivated for numerous passages on media with various heterologous serum supplements (Table 1). The mouse *L*-strain as the oldest established cell line in continuous culture was originated as early as 1943[11]. Treatment with carcinogens resulted in malignant and pronounced chromosomal changes. These characteristics were shown to vary considerably in individual sub-lines[9,10]. Yet, my results show no aberration from mouse-specific antigenicity in any of the *L*-cell lines tested (Table 1). Results with treated HeLa cells (Table 2) proved species-specific antigenicity to be remarkably stable under various 'normal' and experimental cell culture conditions. Deep freezing is used to preserve viable cell cultures. X-irradiated cells are used as 'feeder layer' cultures since X-irradiation blocks cell multiplication without inhibiting metabolic cell functions[12]. Trypsinization is a routine procedure for dispersing cells from monolayer cultures. This treatment has been shown to result frequently in chromosomal 'breaks' and is suspected to be one of the causative factors of progressive chromosomal alteration in continuous cell lines[13]. Cell strains investigated in this work had been routinely trypsinized during each preceding passage. Apart from this I thought, but could not verify, that trypsinization might have a direct effect on species-specific hæmagglutinogens if these were proteinaceous substances located only in the cell surface.

From these experiments the conclusion was drawn that cell 'transformation' with resultant species change is more likely due to laboratory cell contamination than to a genetic process. Methods based on species-specific antigenicity appear to be useful for permanent identification or classification of cell cultures.

This work was aided by research grants to the late Dr. J. T. Syverton, whose interest was invaluable, from the American Cancer Soc., Inc., the National Foundation and grant No. C–4559 from the National Cancer Institute, National Institutes of Health, U.S. Public Health Service.

FOOD SELECTION BY SILKWORM LARVÆ

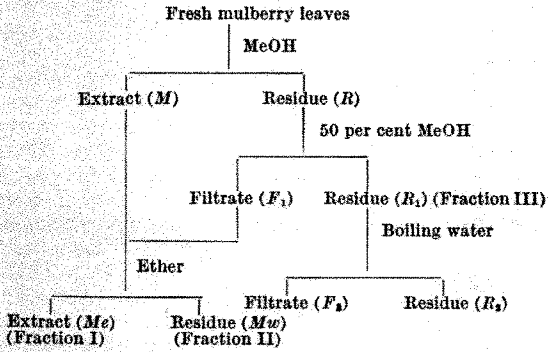
By YASUJI HAMAMURA, KEIZO HAYASHIYA, KEN-ICHI NAITO, KEIKO MATSUURA and JUN NISHIDA

Biochemical Laboratory, Kyoto University of Industrial Arts and Textile Fibers, Kyoto, Japan

Water-Soluble Biting Factors

IN a previous paper[1] we reported the presence of three stimulants in mulberry leaves: attractants, biting factors and swallowing factor, in the preferential selection of food by silkworm larvæ (*Bombyx mori*). The attractants and one of the biting factors occur in methanol and ether-soluble fraction of the leaves (scheme 1), and water-soluble biting factor exists in methanol- and water-soluble but ether-insoluble fraction, and the swallowing factor which appears to stimulate continuous swallowing by the larvæ, is present in the residue insoluble to these solvents.

SCHEME 1



A combination of these factors is of importance for the positive acceptance of the food by the larvæ. This relation may be seen more clearly by the supplementary data (Table 1). Further, we reported that citral or some terpene[2] and β-sitosterol[3] which are isolated from ether extract of mulberry leaves, attract and stimulates the biting action[4], respectively, and these chemicals are used as substitutes for the methanol- and ether-soluble fraction for the food acceptance by silkworm larvæ.

This communication is concerned with the second fraction soluble in methanol and water. From the second fraction we isolated isoquercitrin (a flavonoid)[5], inositol[6], sucrose, fumaric acid, etc.[7]. Isoquercitrin stimulated the biting action of silkworm larvæ (Table 2). Morin[8] from *Morus tinctoria* also showed the same activity, and related substances such as rutin, quercetin belonging to flavonoids, showed little activity.

We call these substances water-soluble biting factors. Though the water-soluble biting factors cause lower activity than β-sitosterol, these flavonoids are of importance in the mechanism of food selection. But the second fraction cannot be substituted by them. To substitute the second fraction by chemically pure substances, inositol and sucrose in addition to isoquercitrin are necessary for complete acceptance of food by the silkworm. Inositol and sucrose do not stimulate the biting action, but seem to be concerned

Table 1

	No. of fæces after 18 hr.
Basal diet (B.d.) only	41
B.d. + leaf powder (5 gm.)	195
B.d. + *Mw*	86
B.d. + *Me*	55
B.d. + R_1	80
B.d. + *Mw* + *Me*	84
B.d. + *Mw* + R_1	131
B.d. + *Me* + R_1	102
B.d. + *Mw* + *Me* + R_1	200

Five silkworms at fifth instar were placed on the food. B.d. consisted of 50 c.c. of 2 per cent agar solution containing 1 per cent sucrose and 5 gm. cellulose powder.

Table 2

	Test of biting action
β-Sitosterol	+ + + + +
Isoquercitrin	+ + + − −
Morin	+ + + − −
Inositol	− − − − −
Sucrose	− − − − −

The test of biting action was done by the method described in the previous paper. + + + + + denotes that all the larvæ bite the agar thread, and − − − − − denotes none of the larvæ bite with the taste of the food[9]. We have temporarily named them co-factors (Table 3). In a previous paper[1], we used the basal substrate consisting of agar solution containing sucrose and cellulose powder to test for the continuous swallowing reaction. The addition of sucrose was to give the food a desirable taste.

Table 3

	No. of fæces after 32 hr.
Basal diet (B.d.) only	0
B.d. + leaf powder (0·4 gm.)	192
B.d. + β-sitosterol + R_1 (0·4 gm.)	89
B.d. + β-sitosterol + inositol + R_1	200
B.d. + β-sitosterol + morin + R_1	206
B.d. + β-sitosterol + inositol + morin + R_1	254
B.d. + β-sitosterol + inositol + isoquercitrin + R_1	226
(B.d. − sucrose) + β-sitosterol + inositol + morin + R_1	60

Ten newly hatched silkworms were placed on the food. B.d. consisted of 3 c.c. of 2 per cent agar solution containing 1 per cent sucrose and 0·7 gm. cellulose powder. When leaf powder or R_1 was added, 0·3 gm. cellulose powder was used.

Swallowing Factor

The third factor in the mechanism of food selection by the silkworm—the swallowing factor—is contained in a residue insoluble in ether, methanol and water. We have suggested the presence of some chemically active substances as the swallowing factor in hot-water extract of the residue, but importance is attached to cellulose itself. As reported previously, we have added cellulose powder to the basal substrate to test for the continuous swallowing reaction. The addition of this powder was to make the test quantitative, that is, to let the food pass through the alimentary canal and to make well-shaped fæces. It was made clear that cellulose powder which was added to the basal diet from the outset of our experiments is an indispensable factor in the mechanism of food selection. But the third fraction, the residue of mulberry leaves extracted with methanol and water, cannot be substituted so completely by chemically pure cellulose powder. The boiling-water extract or glacial acetic extract is necessary in addition to cellulose power for acceptance of food by silkworms. In the boiling-water extract of the residue we detected large amounts of silica and phosphate. It was observed that potassium phosphate and coated silica on cellulose are of importance, as shown in Table 4. The role satisfied by the residue was substituted by the use of phosphate and silica in addition to cellulose powder. Phosphate and silica are to be called as co-factors.

Table 4

	No. of fæces after 32 hr.
Basal diet (B.d.) only	0
B.d. + leaf powder (0·4 gm.)	192
B.d. + β-sitosterol + inositol + morin + *R–Ac* + R_2	160
B.d. + β-sitosterol + inositol + morin + phosphate + R_2	204
B.d. + β-sitosterol + inositol + morin + phosphate	127
(B.d.–*C.P.*) + β-sitosterol + inositol + morin + phosphate	68
(B.d.–*C.P.*) + β-sitosterol + inositol + morin + phosphate + *S–C.P.*	162

Ten newly hatched silkworms were placed on the food. B.d. consisted of 3 c.c. of 2 per cent agar solution containing 1 per cent sucrose and 0·7 gm. cellulose powder. When leaf powder of R_2 was added, 0·3 gm. cellulose powder was used. *S–C.P.*, cellulose powder coated with 5 per cent of silica sol; *R–Ac*, acetic acid soluble matter from R_1; (B.d.–*C.P.*), basal diet free of cellulose powder).

Thus, the principal members in the mechanism suggested in the previous communication are: *attractants*: citral, terpinyl acetate, linalyl acetate, linalol and β-γ-hexenol; *biting factors*: β-sitosterol and isoquercitrin or morin; *swallowing factor*: cellulose; and co-factors: sucrose, inositol, inorganic phosphate and silica.

Agar jelly containing these stimulants in the following proportion was eaten by the larvæ almost as readily as the mulberry leaf itself:

Principal factors	
Citral	1 c.c. (10 mgm. per cent ether solution)
β-Sitosterol	5 mgm. (spray on the surface)
Isoquercitrin or morin	3 mgm.
Cellulose powder	700 mgm.
Co-factors	
Sucrose	30 mgm.
Inositol	5 mgm.
Potassium phosphate	10 mgm.
Silica	40 mgm. (coated on cellulose)
2 per cent agar solution	3 c.c.

Note: Citral and other terpenes as attractants are not necessary for the larvæ placed on this food.

Investigations of the mechanism of food selection by silkworm may be concluded by the isolation of these stimulants from mulberry leaves. Work on the nutrients or other problems which are necessary for feeding of silkworm through succeeding generations are being investigated.

This work was supported by a grant from the Ministry of Education and one from the Press Asahi.

A NEW VERTEBRATE FAUNA FROM THE EARLY JURASSIC OF THE DECCAN, INDIA

By Dr. SOHAN LALL JAIN, Dr. PAMELA LAMPLUGH ROBINSON
and TAPAN K. ROY CHOWDHURY

Geological Studies Unit, Indian Statistical Institute, Calcutta, and
Department of Zoology, University College, London

ONE of the most serious gaps in our knowledge of the evolution of Mesozoic terrestrial vertebrates is due to the absence of a good land fauna of Lower Jurassic age. Wherever fossiliferous rocks of certain Lower Jurassic date occur they are marine deposits, yielding a great variety of invertebrates and a good fauna of fossil fishes, crocodilians, plesiosaurs and ichthyosaurs. In these rocks terrestrial vertebrates are represented by very occasional fragments washed into the Lower Jurassic seas, and by one good skeleton of a stegosaurian dinosaur from the British marine Lias. Two terrestrial vertebrates which may possibly be Lower Jurassic come from the continental deposits of the Kayenta formation (Welles[1] terminology) of North America, and consist of a crocodilian *Protosuchus richardsoni*, and a carnivorous saurischian dinosaur *Megalosaurus wetherilli*. Welles[1], in a preliminary study of the dinosaur, compared it with Upper Triassic, and Middle and Upper Jurassic megalosaurs, and concluded that the structure of *M. wetherilli* suggests a Lower or Middle Jurassic age for the Kayenta formation. Fragmentary remains of a large sauropod dinosaur, *Rhoetosaurus brownei*[2] from the Walloon Series of Queensland, and one or two incomplete sauropod bones from Argentina[3], may be Lower or Middle Jurassic in age. The tritylodont mammal-like reptile *Oligokyphus* was found in a fissure-filling of Lower Jurassic age in Somerset, England[4]. Although it was represented by dissociated bones these were so abundant that they allowed detailed knowledge and a full reconstruction. Thus, three good specimens of terrestrial vertebrates, and some fragments, represent our entire knowledge of early Jurassic land faunas.

Yet the evolution of land faunas was at a particularly interesting stage in Lower Jurassic times. The two orders of dinosaurs must then have been deploying in an adaptive radiation the results of which are seen in the excellent faunas from Upper Jurassic and Cretaceous rocks. Other kinds of reptiles, and early mammals, and possibly early birds, can be expected from Lower Jurassic land deposits, so that the meagre number of specimens actually known is disappointing. The purpose of this article is to make a brief preliminary report of the first discoveries of a land fauna from the Deccan, India, which we believe to be of Lower Jurassic age, and which we therefore hope may make a contribution towards filling the gap in our knowledge of the evolution of terrestrial Mesozoic vertebrates.

The River Godavari flows to the eastern seaboard of the Indian peninsula and receives, as one of its major tributaries, the River Pranhita. Along the valley of these two Rivers occur outcrops of the Gondwana Group of rocks. One member of the Gondwana Group, the Kota formation, contains thin bands of limestone, and during the nineteenth century fossil fishes were discovered near the village of Kota, on the bank of the River Pranhita, in one of the limestone bands. The fishes were recognized to be species of three genera, *Tetragonolepis*, *Dapedium* and *Lepidotes*[5]. All three genera are well-known members of European marine fish faunas of Lower Jurassic (Liassic) age, *Dapedium* ranging through the Lias, *Tetragonolepis* being confined to the Upper Lias, and *Lepidotes* including the Lias in its long time-range from Rhætic to Cenomanian. These fishes suggest that the age of the Kota formation is Lower Jurassic. But the Kota formation, like all the other members of the Gondwana Group in this part of the Pranbita–Godavari Valley, is a terrestrial deposit, consisting of fluviatile and lacustrine sands and clays, and thin limestones representing evaporite deposits formed in inland lakes. The attempt to find Lower Jurassic land vertebrates in the Kota formation was therefore one of the objects of expeditions made to the Pranhita–Godavari Valley during the past few years by members of the Geological Studies Unit, Indian Statistical Institute, Calcutta, and of University College, London.

In the field season 1958–59 a large number of fragmentary bones was discovered in the Kotas, as surface finds. The size and character of these remains suggested that they were dinosaurian. In 1960–61 an excavation of the site revealed an extraordinarily rich layer of bones, at the junction of a sandstone with a clay lens, and lying about twenty feet below a fish-bearing limestone band. About ten tons of bones were excavated from an area about 85 ft. × 35 ft., and transported to Calcutta, where preparation of the bones has begun. No complete associated skeletons were obtained, but partial associations were met with. The bone bed is reminiscent of a log jam in a river, and indeed large logs of wood, up to 10 ft. 6 in. long, occur with the bones. The directions of current-bedding in the sandstone suggest that excavation is proceeding 'upstream', and it is hoped that in future excavations corpses piled up behind the 'jam' may eventually be revealed as associated skeletons.

A proper discussion of the different kinds of dinosaurs represented in this new fauna, and their characters, will not be possible until preparation of the bones, and further excavations, have been carried out. As this will take some time, a few preliminary statements can be made, but must be regarded as very provisional. The majority of bones are those of a sauropod, the largest femora discovered being almost 5 ft. long, though smaller individuals are represented. Most of the bones of the skeleton of the sauropod are represented in the 1960–61 collection, except skull, feet and radius. In view of their early age the possibility of confusion of these bones with those of a prosauropod is a question which is bound to arise. However, the characters of the vertebræ, pubis, tibia, ulna and humerus, for example, are wholly sauropod. A peculiarity of the Kota sauropod lies in the proportions of its limb bones. An ulna almost 3 ft. long has a shaft which narrows to a diameter of 3 in. Femora are also elongate with a relatively small diameter, and tibiæ have a moderately slim 'waist' to their shafts. Fairly slender proportions are known as rather rare varieties of some sauropods, except *Barosaurus africanus*[6], where they are more common. If the present collection is a representative sample of the Kota sauropod, then this beast should prove even more generally slender-limbed than *B. africanus* (which has a comparable size-range) and may pose some interesting problems in functional anatomy and adaptation. A carnosaur is also present, but less well represented than the sauropod in this first collection. Judging by its pelvis, it should prove to be of about the same size as the well-known *Antrodemus valens* from the Upper Jurassic Morrison formation of North America; that is, more than 30 ft. long. One and possibly two other kinds of dinosaur are represented but diagnosis is not yet possible.

In considering the age of these dinosaurs the possibility arises that the fishes *Tetragonolepis* and *Dapedium* may have continued to exist in fresh waters after their extinction in a marine environment. It is unlikely, however, that they did so for long, for freshwater fish faunas of Upper Jurassic age are known, and are sufficiently different from those of the Lias to suggest that they are the results of a process of evolution and migration extending well back into Middle Jurassic times. It is improbable that the Kota formation is younger than early Middle Jurassic (Inferior Oolite) at latest. Fragmentary remains of a crocodilian have been found in the Kota limestone and if good specimens can be discovered these may be helpful in dating the Kotas, as Lower Jurassic crocodilians are well known from the European Lias.

Only a small part of the Kota formation has been prospected, and it is hoped that eventually discoveries may be made of the less-sizable members of its terrestrial fauna, to extend our knowledge of the evolution of land vertebrates in Lower Jurassic times.

We thank the authorities of the Indian Statistical Institute, Calcutta, for financing the expedition, and the Institute's director, Prof. P. C. Mahalanobis, and the head of its Research Division, Prof. C. R. Rao, for their encouragement of the work. We also thank the Royal Society for providing a grant to buy field equipment, and Prof. P. B. Medawar and Prof. Hollingworth, University College, London, for their interest and help. We are grateful to Mr. N. V. Raja Reddy, of Bhimaram, and to Dr. Bimalendu Raichaudhury, Mr. T. S. Kutty, and Mr. D. K. Rudra for their assistance in the field work.

VARIATION OF YEAST RIBOSOMES WITH NUTRITIONAL STATE

By Dr. J. K. KOEHLER*

Donner Laboratory, University of California, Berkeley 4, California

ALTHOUGH a great deal of research has been carried out in recent years on the physicochemical properties of bacterial and yeast ribosomes, relatively little work has been devoted to the discovery of variations in these properties concomitant with physiological changes in the cells of origin. Wolfe[1], and more recently Ashikawa[2], using ultracentrifugal methods, have found that old or starving yeast cells contain predominantly 80*S* particles and that several new components arise when cells are placed into nutrient. I shall present in this article more detailed information on these changes, including electron microscope as well as ultracentrifugal data.

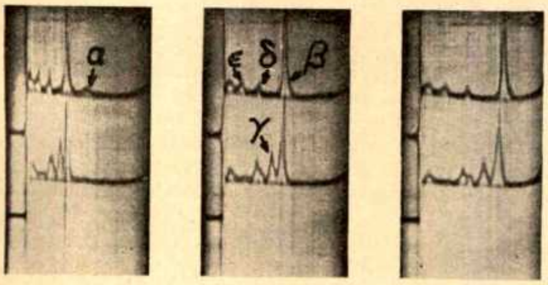

Fig. 1. Ultracentrifuge pattern of yeast ribosomes suspended in Chao and Schachman's buffer at *p*H 7·5. Schlieren photographs are taken 2 min. apart after reaching the speed of 62,500 r.p.m. Top pattern, ribosomes isolated from cells 72 hr. in starvation medium; bottom pattern, from cells 4 hr. in nutrient medium

Cells of baker's yeast (*S. cerevisae*) were cultured in nutrient medium containing 1 per cent yeast extract, 1 per cent peptone and 1 per cent dextrose. The cells were starved of nitrogen in a succinate medium buffered to *p*H 5·0 with potassium hydroxide. All cultures were continuously shaken in Erlenmeyer flasks at 30° C. Samples of cells (about 5 gm. wet) were taken at various times throughout the growth and starvation cycles and hand ground in a mortar with 'Carborundum'. The ribosomes were isolated utilizing the usual centrifugal procedures in the Mg^{++} buffer of Chao and Schachman[3]. Aliquots of each preparation were used for parallel electron microscopy and ultracentrifugal analysis.

Fig. 1 typifies the sedimentation patterns of the ribosomes obtained from physiologically differing cells. The top pattern represents ribosomes from cells after 72 hr. in succinate starvation medium, and the bottom pattern shows a ribosome preparation from cells incubated for 4 hr. in growth medium. Note the complete absence of the γ- or 65*S*-peak from the starved ribosome preparation. Sedimentation constants, corrected for concentration and water viscosity (20° C.),

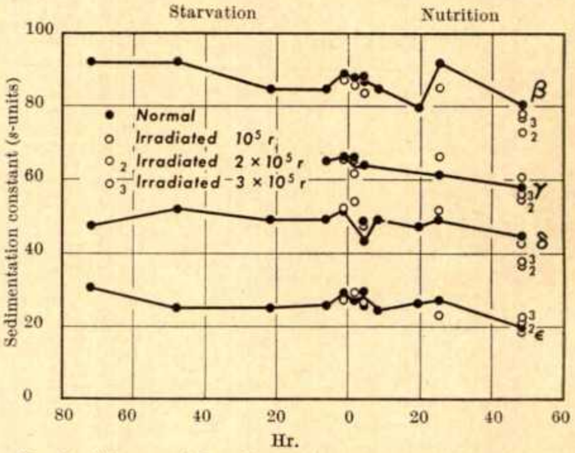

Fig. 2. The corrected sedimentation constants of the various ribosome components as a function of the nutritional state of the original cells

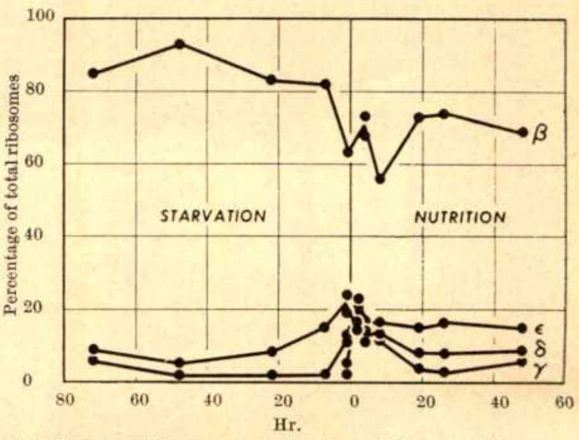

Fig. 3. The relative percentage abundance of the various ribosome components as a function of the nutritional state of the original cells

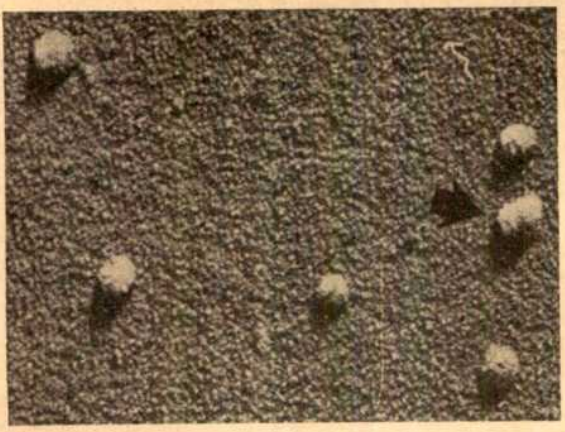

Fig. 4. Electron micrograph of nichrome-shadowed yeast ribosomes. (× *c.* 120,000)

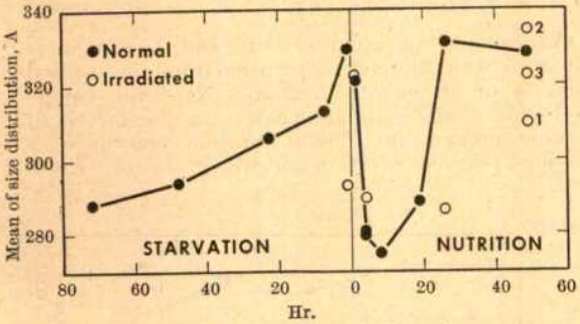

Fig. 5. The mean of size distributions of yeast ribosomes from various nutritional states as calculated from electron microscope observations

and the relative percentage abundances were calculated for the various components. The data are plotted so as to relate these parameters to the physiological state of the cells from which the ribosomes were isolated. Fig. 2 gives the sedimentation constant data for yeast ribosomes. It can be seen that there are four distinct size classes ranging from about 30*S* to 90*S* with the γ-ribosome existing only during the growth phase. Also present, particularly in starved preparations, is the α- or 120*S*- component which does not appear in this figure. Although there are apparent fluctuations of *S* with the nutritional state of the cells, essentially all the data can be fitted with straight lines having a slight negative slope ranging from 0·03 to 0·10*S* per hr. This would suggest that ribosomes isolated from starving cells are larger or denser than their counterparts isolated from cells suspended in nutrient. In the hope of splitting some of the ribosome components, certain samples were irradiated with X-rays. The open circles represent these samples and are seen to be little affected in terms of sedimentation behaviour. Fig. 3 shows the relative percentage of the various components as a function of cell nutrition. The 80*S* particles are always the majority component; however, during starvation these particles represent 85–90 per cent of the total, while during growth they average about 70 per cent. Concomitant with this decrease in 80*S* particles is the appearance of the γ- or 65*S*-ribosome. During early growth phase these particles represent about 20 per cent of the total and decay to just a few per cent within 20 hr. The 120*S* particles have again been omitted from this representation due to their minute abundance and the difficulty of making accurate measurements on the small, diffuse peaks.

Visualization of the various ribosome preparations in the electron microscope revealed no obvious differences in structure among the physiologically varying cells. This should be expected from the rather slight differences noted with the more sensitive ultracentrifugal analysis. Fig. 4 illustrates a typical ribosome preparation after shadowing with nichrome. Note the dimeric particle (arrow) and the clefts in some of the other particles. The sizes of ribosomes from each physiologically differing sample were carefully measured from enlarged electron micrographs and histograms were constructed. Fig. 5 gives the mean of each histogram as a function of cellular nutrition. Each point represents approximately 100 particle measurements. There is a decided drop in mean size at the onset of growth. This would indicate either a general shift of the entire population or the diminution of one or more of the larger-size classes with respect to the smaller classes. The hydrodynamic data indeed show that 65*S* particles appear and that 80*S* particles diminish in relative abundance at this time. The open circles again represent irradiated samples and vary in no interpretable manner from the controls.

The earlier studies of Wolfe[1] and Ashikawa[2] indicating that the hydrodynamic properties of yeast ribosomes are dependent on the physiological state of the cell of origin have been generally supported by this research. Both the sedimentation constants and relative quantity of the various components change in characteristic ways throughout growth and starvation. Histograms of sizes of ribosome measured

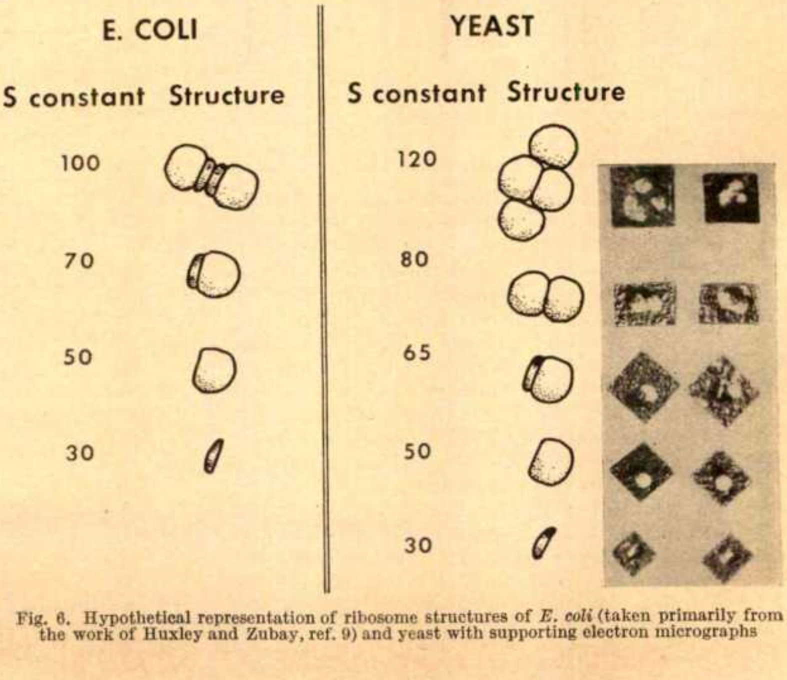

Fig. 6. Hypothetical representation of ribosome structures of *E. coli* (taken primarily from the work of Huxley and Zubay, ref. 9) and yeast with supporting electron micrographs

from electron microscope observations also reflect these changes. The most striking difference between starved and growing cells is the rapid appearance of a 65*S* ribosome at the onset of growth, whereas this component is completely absent in starving yeast cells. Peterman[4] has very recently reported the occurrence of a 65*S* ribosome in a mammalian cancer strain, again linking this particle to active growth processes.

Although the general consensus favours the theory that ribosomes represent the synthetic site for cellular proteins, several dissenting claims have been voiced. Osawa and Hotta[5], in their investigations of turnover procedures utilizing tagged amino-acids, suggest that, in growing yeast cells, "the RNA particles do not represent the precursors for soluble protein". Similar views have been expressed for the *E. coli* system by Roberts *et al.*[6], although a very recent report by McCarthy and Aronson[7], working in Roberts's group, suggests that small RNA (4–8*S*) builds up 20, 30 and 50*S* ribosomes which in turn produce 70*S* particles acknowledged to be active in protein synthesis. Recent work of Tissieres *et al.*[8] indicates that the incorporation of labelled amino-acids in *E. coli* is not uniform over the various ribosome size classes. A special kind of 70*S* ribosome called 'active 70*S*' was shown to incorporate 15–40 times more amino-acid than the 30 or 50*S* particles, and constitutes only 10 per cent of the total ribosome complement. It is possible that the 65*S* yeast ribosome plays a similar part and might help in explaining its rapid appearance during the early growth stage.

Huxley and Zubay[9], working with *E. coli* ribosomes, have shown by the use of positive uranyl and negative phosphotungstic staining techniques that the 100*S* particles constitute two 70*S* particles in dimeric form. The 70*S* units in turn contain two sub-units probably representing 50 and 30*S* particles. It was further shown that 50*S* units could combine under the proper conditions to form 80*S* particles. It is possible that the predominant 80*S* units of yeast are of this structure, and that the 65*S* units are actually the 70*S* units of Huxley and Zubay, the difference being of the order of magnitude of the errors involved in the ultracentrifugal determination. That there may be a significant difference between *E. coli* and yeast ribosomes is substantiated by the observation of a 120*S* component in yeast rather than 100*S*. This may represent the dimerization of 80*S* rather than 70*S* particles. Fig. 6 gives the comparative structures and sedimentation-rates for *E. coli*, derived primarily from the work of Huxley and Zubay, and yeast ribosomes as they are at present believed to exist. It must be stated that no definitive evidence has been obtained favouring the existence of the quadruple 50*S* particle representing the 120*S* ribosome.

This investigation was supported in part by the U.S. Atomic Energy Commission and in part by a pre-doctoral fellowship from the National Cancer Institute, U.S. Public Health Service.

PREPARATION OF CRYSTALLINE *PSEUDOMONAS* CYTOCHROME OXIDASE AND SOME OF ITS PROPERTIES

By Dr. T. YAMANAKA, S. KIJIMOTO and Prof. K. OKUNUKI

University of Osaka

AND

Dr. K. KUSAI

Nagase and Co., Ltd., Amagasaki-shi, Japan

FROM the anaerobically cultivated cells of *Pseudomonas aeruginosa*, a cytochrome which has all the properties of a cytochrome oxidase has been purified in an ultracentrifugally homogeneous state, and it was named *Pseudomonas* (*P.*) cytochrome oxidase[1,2]. The *P.* cytochrome oxidase has two hæms, hæm a_2 and a *c*-type hæm, in the molecule, and consequently shows a complicated absorption spectrum. In addition, a preparation of this oxidase acts as a nitrite reductase, and it is very likely that the enzyme is responsible for the nitrite-reducing activity of the organism. The previously reported *P.* cytochrome oxidase preparation, although ultracentrifugally pure, contained some 30 per cent impurities judging from electrophoresis. We recently obtained the enzyme in a crystalline state as described here.

The acetone powder of the cells, cultivated in a submerged culture in the presence of potassium nitrate, was extracted with 0·1 *M* citrate at *p*H 7·0, and the cells were discarded by filtration. To the filtrate obtained, after treatment with rivanol, ammonium sulphate was added until saturation was reached, and the precipitate was collected. The precipitate, after dissolving in a minimum amount of water, was dialysed against water overnight at 5°, and further dialysis was performed overnight against 0·02 *M* ammonium phosphate at *p*H 6·0, at 5°. When the dialysate was passed through an 'Amberlite *CG*-50' column, which had been equilibrated at *p*H 6·0 with 0·02 *M* ammonium phosphate, *P.* cytochrome oxidase was adsorbed on the column, and formed a green band. The resin, on which *P.* cytochrome oxidase was adsorbed, was washed with 0·02 *M* ammonium phosphate (*p*H 6·0) until the eluate became colourless and clear. Then *P.* cytochrome oxidase was eluted by 0·3 *M* ammonium phosphate (*p*H 7·0). The first and last parts of the eluate were

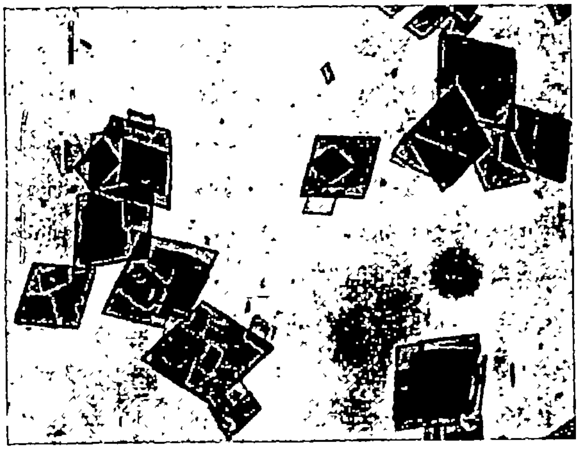

Fig. 1. Photograph of the crystals of *P.* cytochrome oxidase. Twice recrystallized crystals were washed with a small amount of water and then separated from the supernatant. (× 180)

discarded, and the middle part of the eluate, which was green in colour, was used in the subsequent procedure.

Ammonium sulphate was added to the green eluate until saturation was reached. The collected precipitate was dissolved in a small amount of 0·01 *M* phosphate buffer (*p*H 6·0), and followed by centrifugation to discard insoluble material. Solid ammonium sulphate was added to the supernatant until the solution became slightly turbid. The solution was centrifuged, and the precipitate was discarded. The supernatant was allowed to stand at room temperature for 30–60 min., and light-green, diamond-shaped crystals appeared. The collected crystals were dissolved in the 0·01 *M* phosphate buffer (*p*H 6·0), and the recrystallization was carried out by adding ammonium sulphate as described here. The crystals, twice recrystallized, were collected and washed with a very small amount of distilled water, and the crystals separated from the supernatant were used as a *P.* cytochrome oxidase preparation. Among *a*-type cytochromes, cytochrome *a* from bovine heart muscle has been obtained in a crystalline state, but it was found to contain a small amount of detergent[3]. The *P.* cytochrome oxidase, which may be classified as an *a*-type cytochrome on the basis of its absorption characteristics, was crystallized without any detergent as described above.

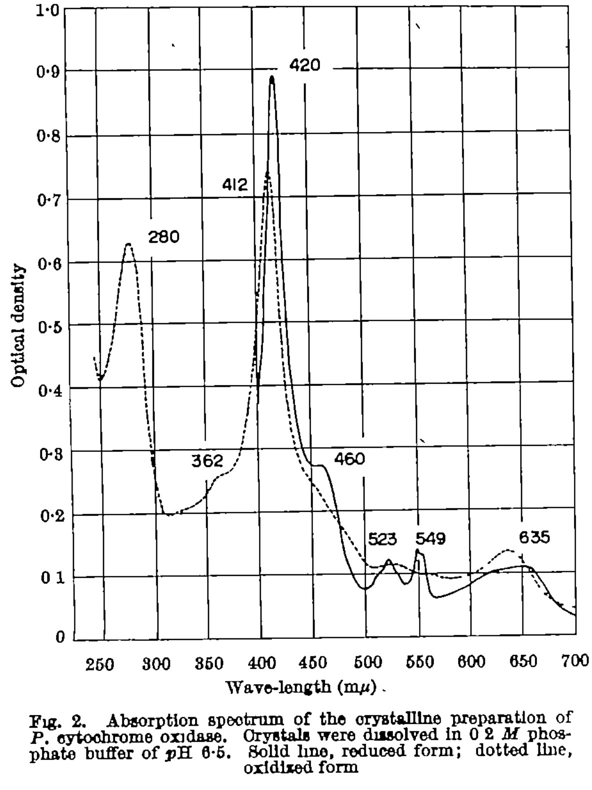

Fig. 2. Absorption spectrum of the crystalline preparation of *P.* cytochrome oxidase. Crystals were dissolved in 0 2 *M* phosphate buffer of *p*H 6·5. Solid line, reduced form; dotted line, oxidized form

The crystalline preparation of *P.* cytochrome oxidase showed a complicated absorption spectrum (Fig. 2). There were absorption peaks at 280, 412, 525 and 635 mμ, and humps at 362 and 562 mμ, in the oxidized form. In the reduced form, there were peaks at 420, 523 and 549 mμ, and humps or shoulders at 460 and 554 mμ, and a plateau between 620 and 660 mμ. The remarkable difference between the *P.* cytochrome oxidase preparation described previously and the one obtained here is that the previous preparation showed a peak at 625 mμ by reduction, while, in the crystalline preparation, the peak at 635 mμ in the oxidized form was depressed by reduction with sodium dithionite, and a plateau appeared between 620 mμ and 660 mμ in the reduced form. By the re-oxidation of the crystalline preparation with potassium ferricyanide, the absorption peak at 635 mμ appeared again. It was also noticeable that the peak at 554 mμ in the previous preparation became a shoulder in the crystalline preparation. In the present preparation, $E_{412\,m\mu}/E_{280\,m\mu}$ was very high (1·2), which is not comparable with the value for the previous preparation ($E_{408\,m\mu}/E_{278\,m\mu} = 0{\cdot}87$) (where E is the optical density at the indicated wave-length). This indicates that the crystalline preparation is very pure. By reduction, a hump appeared at 460 mμ, which may be the γ-band due to hæm a_2.

By treatment with acetone containing 0·12 *M* hydrochloride, the precipitated protein showed an absorption spectrum of a *c*-type cytochrome. The hæm extracted in the acetone layer was confirmed as hæm a_2 by the formation of its pyridine hæmochromogen. These facts confirm that *P.* cytochrome oxidase itself has hæm a_2 and a *c*-type hæm in the molecule, as reported previously.

It was also reported previously that *P.* cytochrome oxidase had general properties of a cytochrome oxidase, and acted also as a nitrite reductase[4,5]. These properties were confirmed by using the crystalline preparation. Therefore, these enzymatic properties were for the single enzyme, *P.* cytochrome oxidase (= *P.* cytochrome *c*–551 : oxygen or nitrite oxidoreductase[6]). Thus, it is very likely that the *P.* cytochrome oxidase is responsible for the nitrite reductase activity of the organism.

This work was supported in part by research grant *RG*–5871 from the U.S. National Institutes of Health, and by a research grant from the Institute for Protein Research, University of Osaka.

LETTERS TO THE EDITOR

GEOPHYSICS

Atmospheric Blow-up at the Auroral Zone

ELSEWHERE[1,2] I have examined joule heating of the upper atmosphere by those ionospheric electric currents which cause geomagnetic disturbance. Some further consequences were recently reported[3]. It is the purpose of the present communication to point out that in regions of the auroral ionosphere above about 150 km. altitude the scale height may increase 5- to 10-fold during geomagnetic disturbance. This would cause population of the exosphere to great heights with ionospheric gases and even loss of a portion of such gases to the interplanetary medium.

Joule heating in the auroral ionosphere is rapid. In the event of no loss of heat by conduction or convection it would cause the scale height at 160 km. altitude to double in a matter of seconds[1,2], whereas the electric currents responsible flow for periods of order 0·5 hr. Let us estimate the effect of convection and conduction on the process of increasing the scale height. Suppose an auroral electrojet is 100 km. wide in latitude cross-section. Winds of the order of 100 msec.$^{-1}$ are associated with the likely gradients of pressure[2]. Such winds would take 10^3 sec. to replenish the air in the electrojet. Thus convection would not inhibit the process of increase of scale height in an electrojet of this size. Now conduction proceeds better at greater heights[4]. Temperature equilibrium through conduction may be established to distances of the order of 1,000 km. in 10^3 sec. at 1,000 km. altitude but only to distances of the order of 10 km. at 200 km. altitude in the same time. Thus a steady model of the dimensions in space and time considered here yields a good approximation to the actual magnetic disturbance conditions in the auroral zones.

It has been shown elsewhere[1,2] that during such steady disturbance the pressure at 200 km. altitude in the auroral ionosphere can be equal to that at 140 km. in temperate latitudes. This represents an increase in scale height at 150 km. by a factor of about five. This calculation was based on only moderate disturbance. At times of increased disturbance the scale height could change by a factor 10. At these times the temperatures at 200 km. altitude would be increased by amounts of order 1,000° K. Such increases in temperature are sufficient to cause the ejection of hot neutral particles upwards and outwards to populate the magnetosphere, where they could be afterwards ionized by solar radiation to modulate the density of the whistler medium. These density fluctuations would in turn cause variations in the low-frequency phenomena in the magnetosphere such as whistler and dawn chorus propagation. Such variations in density of the background medium would modulate the rate of scatter and of degradation of energy of geomagnetically trapped radiation.

The escape of gases from the auroral zone to interplanetary space is also inevitable with such heating[5], the lighter molecules hydrogen and helium having the greatest probability of escape. This would explain the representations of earth gases in the spectrum of the counter glow (Gegenshein)[6] and also their enhancement with geomagnetic disturbance. Conceivably joule heating in the auroral zones plays an important part in the problem[4] of the helium balance in the atmosphere.

The theory suggests that static models of the ionosphere above 100 km. and the exosphere may only be adequate for an average picture. This region is dynamically dependent on geomagnetic disturbance and at a given instant its structure may differ significantly from the average. A bulge must develop in the ionosphere above disturbance electric currents. Moreover, since the movement of ionization across the geomagnetic field is inhibited in and above the F region of the ionosphere, field aligned inhomogeneities in electron density would project upwards from the parent electric current.

PHYSICS

Optical Refractivity of Free Electrons

A NUMBER of experiments have been reported recently in which electron densities have been determined from the refractivity of free electrons in the visible region of the spectrum[1-3]. In none of these, however, has an independent check been made on the values obtained. We wish to report some recent measurements of the optical refractivity of free electrons in a hydrogen plasma in which simultaneous determinations of electron density are obtained from the Stark effect broadening of H_β and H_γ (ref. 4) and from a measurement of the absolute continuum intensity. A measurement of the electron temperature from the ratio of the total line intensity of H_β to the continuum[5] is used to confirm the high degree of ionization obtained and the dominant role of the free electrons in determining the refractive index.

The plasma was produced in an electromagnetic T-tube[6] and the refractivity measured using a Mach–Zehnder interferometer. A commercial xenon flash-lamp was used to produce the fringes which were recorded on a streak camera[7], with a time resolution of $\sim$ 0·1 μsec. The fringe system was perpendicular to the slit of the streak camera and the fringe shift (Fig. 1) recorded as a function of time as the shock passed the plane of observation. An interference filter ($\lambda \sim 5530$ Å.) in front of the slit served to overcome the self-luminosity of the plasma.

The refractive index of free electrons is given by classical dispersion theory. The frequency of light is much greater than the plasma frequency under the

Table 1

Fringe	Interferometer data		N_e ($\times 10^{16}$ cm.$^{-3}$)	Continuum measurement N_e ($\times 10^{16}$ cm.$^{-3}$)		Line width data N_e ($\times 10^{16}$ cm.$^{-3}$)		Electron temperature (eV.)	Degree of ionization
	Shift	Mean		λ 5,200	λ 4,530	H_β	H_γ		
2	0·34 ± 0·03	0·33 ± 0·03	4·5 ± 0·4	5·6 ± 0·7	5·4 ± 0·7	4·8 ± 0·6	4·8 ± 0·7	1·8	~ 100%
3	0·33 ± 0·03								
4	0·32 ± 0·03								

conditions of the experiment, and the refractivity $(n - 1)$ is given by:

$$(n - 1) = 4\cdot46\ 10^{-14}\ \lambda^2 N_e$$

where N_e is the electron density. Collisions of electrons with heavy particles and the effect of magnetic fields can be neglected. At the high degree of ionization achieved the contribution of atomic and molecular hydrogen to the refractivity is less than 1 per cent. The contribution of the protons is negligible, and the fringe shift shown in Fig. 1 is almost entirely due to the free electrons.

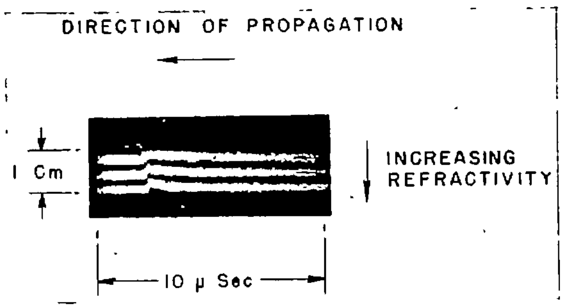

Fig. 1. Monochromatic interferogram (λ = 553 mμ) for a Mach 20 shock into hydrogen at an initial pressure of 0·5 mm. mercury

In Table 1 the values of electron density obtained from the refractive index of the free electrons are compared with values obtained from Stark effect broadening and absolute continuum intensity, agreement being found to within the accuracy of the measurements.

Electron-Hole Scattering at High Injection-Levels in Germanium

THE principal scattering mechanism which determines the mobilities of the charge carriers in pure semiconductors over a wide range of temperature is the interaction with lattice vibrations. According to the calculations of Fletcher[1], interaction between the Coulomb fields of electrons and holes as they drift in opposite directions leads to a progressive reduction in their conductivity mobilities as the injected carrier density increases above 10^{16} cm.$^{-3}$ in germanium at room temperature. Experiments in this laboratory have demonstrated this effect, and a value $m_n m_p/(m_n + m_p) = 0\cdot15\ m_0$ has been obtained for a combined effective mass for electron-hole scattering (m_0 is the mass of an electron in free space).

In my experiments the injected carrier density and conductivity for the central lightly doped (L) region of a p^+–L–n^+ structure are calculated from the p.d. across the structure during and after a current pulse in the forward direction; the technique utilized is similar to that of Lederhandler and Giacoletto[2]. From each measurement a value for the sum of electron and hole mobilities, $\bar{\mu} = \mu_n + \mu_p$, is obtained; the results for one sample are shown in Fig. 1 as a function of the injected carrier density n. Departures from uniformity of the excess carrier distribution in the L-region are taken into account.

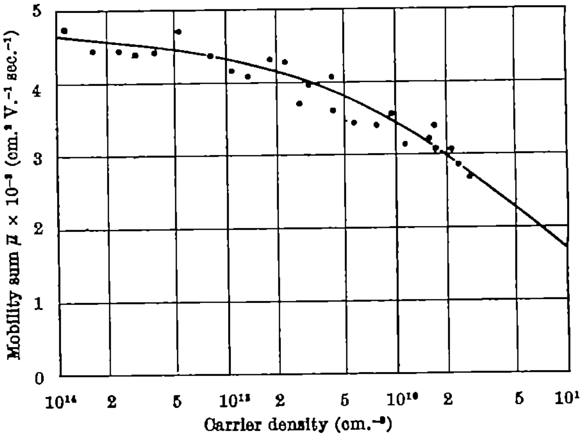

Fig. 1. The sum of electron and hole conductivity mobilities as a function of injected carrier density in germanium at 300° K.

The observed decrease in $\bar{\mu}$ with increasing carrier density is attributed to the effects of electron-hole scattering. In order to separate contributions to the mobility sum by scattering due to lattice vibrations and other imperfections on one hand ($\bar{\mu}_0 = \mu_{n0} + \mu_{p0}$), and by electron-hole scattering on the other hand (μ_{np}), it was assumed that the mobilities may be compounded, as are those for lattice scattering and ionized impurity scattering[3]. The values of μ_{np} calculated in this way are found to be inversely proportional to the carrier density n if $\bar{\mu}_0 = 4{,}800$ cm.^{2} V.$^{-1}$ sec.$^{-1}$, a value consistent with the alloying technique used in the fabrication of the p^+–L–n^+ diode samples. From a series of observations on three samples of varying dimensions and carrier lifetimes we find the empirical relationship:

$$\mu_{np} = 2\cdot5 \times 10^{20}\ n^{-1}\ \text{cm.}^2\text{V.}^{-1}\ \text{sec.}^{-1}$$

for germanium at 300° K., where n is in units of cm.$^{-3}$.

Chapman's classical analysis[4] of the mutual diffusion of two groups of oppositely charged particles has been applied[1] to the interaction of electrons and holes in a semiconductor; in this theoretical treatment, a cut-off approximation was made to the Coulomb fields of the scattering charge carriers. If the screening[5] of distant scattering charges by electrons and holes is taken into account, we obtain the theoretical expression:

$$\mu_{np} = \frac{3K^2(kT)^{3/2}}{\pi^{1/2}2^{5/2}nq^3}\left(\frac{m_n m_p}{m_n + m_p}\right)^{-1/2} \left[\ln \frac{12\pi K(kT)^2}{h^2q^2n}\left(\frac{m_n m_p}{m_n + m_p}\right)\right]^{-1}$$

where K is the dielectric constant, and m_n, m_p are the effective masses of electrons and holes, assumed isotropic; q is the electronic charge.

My experimental result is in agreement with theory if we take the combined effective mass term $m_n m_p/(m_n + m_p) = 0{\cdot}15\ m_0$, and from this reasonable value we conclude that the interpretation of our measurements of the mobility sum μ in terms of electron-hole scattering is justified. The continuous line in Fig. 1 is obtained from the resultant theoretical expression for μ_{np}, compounded with the chosen value of $\overline{\mu}_0$.

The above results are relevant to theories of the current-voltage characteristics of semiconductor rectifiers; for example, the measurements presented in Fig. 1 extend to current densities of 100 amp. cm.$^{-2}$ in the diode, at which stage the mobility sum $\overline{\mu}$ has fallen to 58 per cent of its value at low injection-levels. The experiments are being continued over a range of temperatures with both germanium and silicon, with the aim of further verifying theory and the determination of the combined effective mass term.

I thank W. M. Eades for the fabrication of samples and for assistance with the measurements.

CRYSTALLOGRAPHY

Crystal Growth and Cell of Cellotriose

Examination of the detailed crystal structure of the lower oligosaccharides is of importance in elucidating the structure of cellulose. The single glucose ring exists in three forms, α-glucose, β-glucose and α-glucose monohydrate. The detailed crystal structure of these compounds has already been given[1-3]. The second member of the series is cellobiose in which two β-glucose rings are linked 1 to 4; the detailed crystal structure has recently been given by Jacobson, Wunderlich and Lipscomb[4]. The third member of the series is cellotriose in which three β-glucose rings are joined with two 1 to 4 linkages.

The study of cellotriose is complicated by the extreme difficulty in producing single crystals which are big enough to be used for X-ray diffraction. The two accepted factors influencing the production of single crystals are the rates of nucleation and growth. An extensive study of the growth behaviour of the lower oligosaccharides shows that the nucleation-rate is of primary importance. These substances are soluble in water, the solubility decreasing as the series is ascended. Standard methods of crystal growth were used, namely, precipitation using different solvents, for example, acetone and various alcohols, slow cooling with varying degrees of saturation and evaporation from assorted shapes of vessel under various conditions. In each case and with all materials a high nucleation-rate was observed. The effect was more pronounced as the series was ascended, but even glucose shows a significantly high nucleation-rate and stable saturated solutions such as can be obtained with sucrose are not easily produced. With cellotriose the very high nucleation results in large numbers of very small crystals.

It is a reasonable assumption that the high nucleation results from comparatively large-sized aggregates of molecules in the solution. These would provide a large number of nuclei on which growth could readily take place once the solutions became saturated. It has been pointed out by many observers, for example, Egli and Zerfoss[5], that superheating a solution does reduce the nucleation. The effect of superheating the solution is to reduce the size of molecular aggregates and probably in many cases to disperse them altogether.

Solutions of cellotriose in water (various concentrations) were sealed in thick-walled 'Pyrex' capillary tubes, which were then heated under oil to temperatures approaching 200° C. After this curing process the solutions were treated in the normal way to produce crystals. No observable improvement resulted from slow cooling or evaporation methods possibly because the aggregates had time to reform. However, with solutions immediately treated with acetone, small crystals in the form of curved plates were precipitated. The plates were rectangular in section of dimensions approximately $\frac{1}{2}$ mm. × $\frac{1}{4}$ mm. and of extremely small thickness estimated to be of the order of μ. Their curvature, which gives them the appearance of propellers under the microscope, must arise from growth conditions and is probably due to solution pressure resulting from comparatively fast growth.

It was found possible to mount these crystals in the normal way for X-ray diffraction. Oscillation pictures through 10° were taken about each crystal axis in turn using copper $K\alpha$ radiation. Very long exposures (about 100 hr.) were necessary to produce a reasonable number of detectable reflexions, and the quality of the pictures was poor because of large background and extension of reflexions due to the misorientation produced by their curvature (fibre effect). It was found possible to identify each crystal axis as consistent with a crystallographic axis in an orthorhombic unit cell:

$$a = 29{\cdot}6\ (\pm\ 0{\cdot}1)\ \text{Å.}, b = 15{\cdot}3\ (\pm\ 0{\cdot}1)\ \text{Å.}, \quad c = 4{\cdot}91\ (\pm\ 0{\cdot}03)\ \text{Å.}$$

This gives four molecules in the unit cell and a calculated density of 1·50 (± 0·05) gm. cm.$^{-3}$ compared with an experimental value of 1·56 gm. cm.$^{-3}$.

An examination of the absences is complicated by the large background, and it is only possible to say that a particular reflexion is definitely present. The (001) is observed to be present, and it seems likely that $(0k0)$, k odd and $(h00)$, h odd are absent with no other systematic absences. If these conclusions are correct there is only one possible space group $P2_12_12$. Assuming the size of the cellotriose molecule as approximately 15 Å. × 5 Å., a very reasonable packing arrangement can be obtained with this space group.

It is hoped to produce better single crystals of cellotriose either by an improvement of the present method or by some other method and proceed to a detailed crystal analysis.

Optical Fourier Synthesis for Non-centrosymmetric Projections of Crystal Structures

THE production of an X-ray image showing details of the atomic arrangement in a crystal is not possible because X-radiation cannot be focused; the possibility of representing the diffracted X-ray beams by beams of visible light which can be focused has therefore always been attractive. The first step is, of course, to obtain complete information about the X-ray spectra; it is a fairly simple matter to measure their amplitudes, but it is not possible to record their relative phases experimentally. The determination of the phases is, therefore, the major problem in X-ray diffraction investigations of crystal structures. Once the phases have been determined by one of the many techniques available the production of an 'image' by Fourier synthesis is possible.

The summation process is most often carried out with the help of a digital computer; but several alternative methods have been suggested, for example, the special electronic computer designed by Pepinsky[1], which presents the result as a contoured electron-density map on a cathode-ray tube. The use of optical methods has been described by several workers[2-4]; but these were restricted in practice to projections of structures involving only phase of 0 and π, that is, to centrosymmetrical projections.

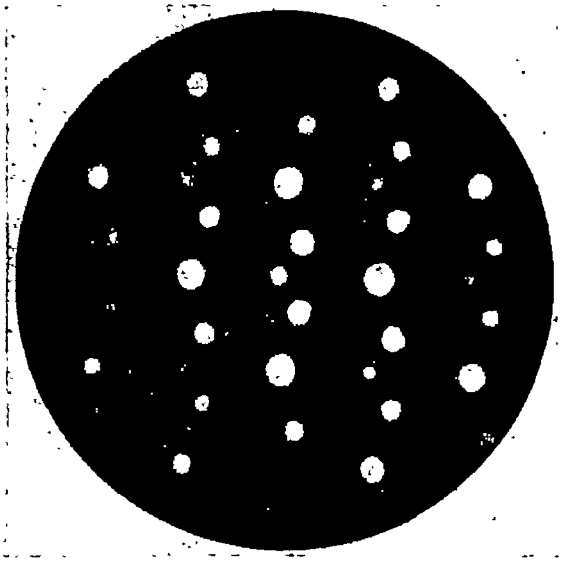

Fig. 1. Optical Fourier synthesis of sodium nitrite Na = N$<^{O}_{O}$

Recently, in extending optical-transform methods to three dimensions, it was necessary to devise a technique providing continuous phase control of light beams[5]. The essential feature of the method is that phase differences in the diffracting mask are obtained by the relative orientations of half-wave plates in a beam of circularly polarized light. At the same time a very satisfactory method for controlling the amplitude of light beams—using gauzes of different transmission factors etched from copper foil—was developed. With both amplitude and phase-control available it is a relatively simple matter to carry out optical Fourier syntheses for structures having non-centrosymmetric projections and the possibilities have been demonstrated by applying the technique to a simple known structure.

Crystals of sodium nitrite ($NaNO_2$) belong to the space group *Imm*; there are two molecules in the unit cell which has dimensions $a = 3{\cdot}55$ Å., $b = 5{\cdot}38$ Å., $c = 5{\cdot}56$ Å. A diffracting mask, representing the $0kl$ reflexions in amplitude and phase, was made according to Carpenter's results[6], and Fig. 1 shows the optical Fourier summation which was obtained. Once a mask representing the observed X-ray amplitudes for an unknown structure has been made any postulated set of signs may be tested very quickly. However, for structures having larger unit cells containing more atoms, some of them perhaps overlapping in projection, the optical technique becomes less favourable and the photographs obtained are not so easy to interpret. In view of these difficulties and because of the general availability of electronic computing facilities the optical method of performing Fourier summation is unlikely to be of great practical value; it remains, however, as an elegant demonstration of the basic physics of Fourier synthesis.

Structure of Calcium Aluminate, $12CaO.7Al_2O_3$

Bussem and Eitel[1] determined the unit cell, space group, and approximate structure of calcium aluminate. From the unit cell (body-centred cubic, $a = 11{\cdot}95$ Å.) and density ($\simeq 2{\cdot}69$ gm./c.c.) the cell contents were fixed as $Ca_{24}Al_{28}O_{66}$. This gives a CaO : Al_2O_3 ratio of 12 : 7 and differs only slightly (0·71 wt. per cent Al_2O_3) from the 5 : 3 ratio proposed on chemical grounds[2]. The most probable space-group appeared to be T_d^6, or $I\bar{4}3d$. Only 64 of the 66 oxygen atoms in the unit cell could be placed in this space-group; the remaining two were assumed to be distributed statistically. Because of this, the structure has been accepted with reservation, and it seemed worthwhile to check it, especially as more powerful methods of structure analysis are now available.

A $12CaO.7Al_2O_3$ preparation (see below) showed only one phase under the petrographic microscope and gave a powder pattern agreeing with that in the literature[1,3]. An equant single crystal was selected for the structure analysis; its rotation photograph matched the powder photograph of the bulk material taken on the same camera. *hk*0, *hk*1, *hk*2 and *hk*3 Weissenberg photographs gave $a = 11 \cdot 98$ Å., in good agreement with Bussem and Eitel's value, and confirmed their space-group.

A series of graduated intensity *hk*0 Weissenberg photographs were taken using unfiltered molybdenum radiation; the intensities of four *h*00 and fifty-two *hk*0 reflexions were measured by visual comparison with an intensity strip. Structure factors calculated from these agreed well ($R \simeq 25$ per cent) with those calculated from Büssem and Eitel's structure, which is, therefore, essentially correct.

$12CaO.7Al_2O_3$ has recently been found to contain 'zeolitic' water[4,5], which is retained up to very high temperatures (1,000–1,100° C.). Crystals prepared at higher temperatures and cooled rapidly in air are anhydrous and do not hydrate readily in air at room temperature. They will, however, hydrate on heating at 400–500° C. This unusual behaviour might be caused by unsatisfactory co-ordination of some of the cations, possibly connected with the presence of the two 'surplus' oxygen atoms, the location of which is still uncertain.

The crystals used in this work were prepared by heating an intimate mechanical mixture of calcium carbonate and alumina (in the ratio 12 : 7) to 1,200° C. for 12 hr., cooling and grinding the sintered cake, and reheating to 1,390° ± 10° C. for several days. The crucible was cooled quickly. Dynamic weight-loss curves showed that the product was essentially anhydrous. It is proposed to refine the structure, and also to collect data for the hydrated material in the hope of locating the 'surplus' oxygen atoms and the water. Independent chemical investigations to establish the CaO/Al_2O_3 ratio and check the melting behaviour of the compound are also being undertaken.

METALLURGY

Dendritic Growth of Graphite from Melts

Observations on the dendritic growth of graphite from nickel–carbon melts have recently been made in this laboratory. Nickel shot containing 0·1 per cent iron and 0·005 per cent cobalt was melted in graphite crucibles. Temperature was held at 1,450° C. to saturate the melt and attain hypereutectic composition. Samples were cooled in each case at the rate of 15° C./min.

A section taken vertically through a solidified button (Fig. 1) displays a micro-structure comparable with that shown by Nipper[1] for cast iron. Extremely large discontinuous plates of primary graphite are observed, separated from eutectic graphite by the α-phase.

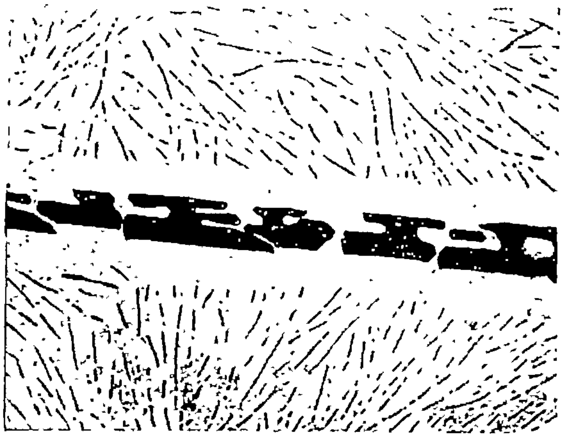

Fig. 1. Unetched. (× c. 75)

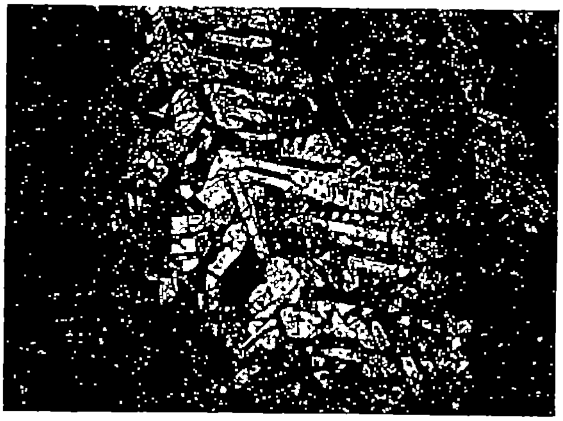

Fig. 2. (× 45)

Crystals of graphite from several of the solidified buttons were extracted by dissolving the specimens in a solution of 1 : 1 nitric acid and by filtering. The large primary flakes of graphite were separable from the fern-like eutectic graphite. These flakes were approximately 2–5 mm. in cross-section and 0·5 mm. thick and exhibited a variety of growth markings on their surfaces. Observations on the manner of growth of the crystals were readily made by removing successive layers of the crystals with 'Scotch' tape.

Fig. 2 shows a characteristic dendritic interior of a crystal with branching occurring in the close-packed plane according to the trigonal symmetry of graphite. In some places, remnants of growth layers from neighbouring sections adhere to the dendrite arms. In Fig. 3, which shows part of the crystal of Fig. 2 at higher magnification, large growth steps are clearly visible. Flat two-dimensional dendritic branching of the steps is observed, the dendritic arms of each step growing independently over the underlying step.

The average step height in the crystal interior was 0·01 mm. while at the surface smaller steps of 0·001 mm height were measured. At the advancing face of the main arm of the crystal, small steps which form the macro-steps were visible.

Careful observation of the upper surfaces of the crystals by light microscopy and by phase-contrast microscopy has so far failed to reveal any growth features characteristic of screw dislocations. Instead, systems of concentric circular steps or hexagonal steps have been observed.

Our observations differ from those summarized by Saratovkin[2], who classified primary graphite crystals grown from melts as "foliated crystals". These were

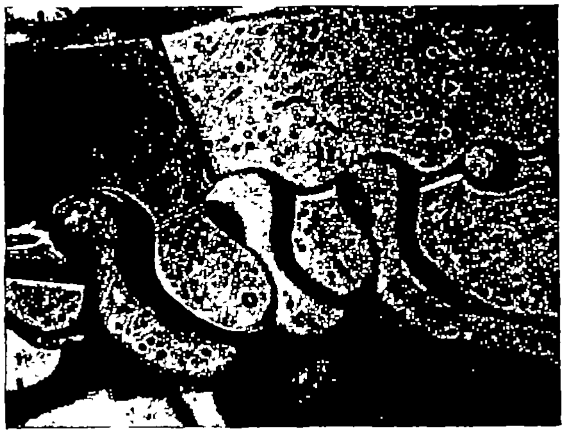

Fig 3. (× 450)

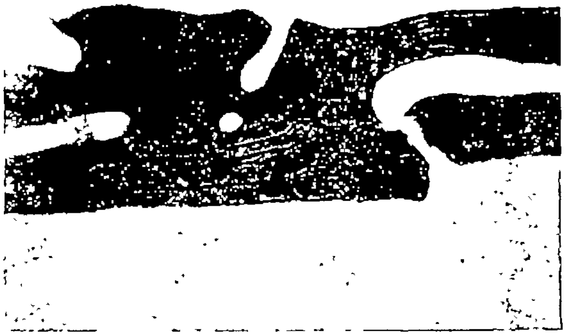

Fig. 4. (× c. 260)

considered as being built up of plates in which screw dislocations play a part in the growth mechanism. Impurity blocking of the screw front would lead to formation of a branch while plates growing from the branch would complete the layered dendritic appearance.

While growth patterns due to screw dislocations have been observed on graphite found in the natural state[3] and on graphite formed by solid state graphitization[4], no direct evidence is available for participation of screw dislocations in the growth of graphite from the melt.

The dendritic graphite observed in the present experiments appears to grow by the repeated nucleation of steps which advance as a series of macro-steps into the liquid. The aggregation of small steps into macro-steps suggests kinetic factors associated with the flow of steps. The layered structure of the crystal is related to the macro-steps and may be observed on etching a prepared microsection in hydrogen peroxide (Fig. 4).

RADIATION CHEMISTRY

Radiation Decomposition of Sodium Chlorate

THE decomposition of alkali chlorates by ionizing radiation has already been examined. In 1959, Heal[1] identified chloride, chlorite, hypochlorite, oxygen, dichlorine hexoxide and chlorine dioxide as the decomposition products from solid potassium chlorate subjected to X-rays. Baberkin[2] reported only chloride, oxygen and chlorite as products of the decomposition of solid potassium chlorate by cobalt-60 γ-rays. The yield of chlorite was 1·2 molecules formed/100 eV. of energy absorbed. In samples afterwards heated to 200° C. the yield of chlorite decreased to 0·8 molecule/100 eV. The decrease in the yield of chlorite was attributed to its decomposition into chloride and oxygen. An investigation of the decomposition of solid sodium, potassium and barium chlorates by cobalt-60 γ-rays has been carried out by Burchill[3]. Oxygen, chlorite and chloride were identified as major products in solutions of the irradiated salts, with smaller amounts of chlorine dioxide, hypochlorite and perchlorate being formed.

The work reported here concerns a more detailed investigation of the effects of annealing previously irradiated sodium chlorate. Irradiations were carried out at room temperature in a commercial cobalt-60 irradiation unit. It was found by chemical analysis of solutions of the irradiated salt that $G_{O_2} = 1·95$, $G_{ClO_2} = 1·34$, $G_{Cl^-} = 0·95$, $G_{ClO_2} = 0·23$, $G_{ClO^-} = 0·21$, and $G_{ClO_4^-} = 0·22$.

Irradiated crystals were heated for varying times at a given temperature, and the effect of this thermal annealing on the G values of all the products was studied. The most striking change was observed to occur in the chloride yield. The variation in G_{Cl^-} is shown in the figure. On annealing at 50°, G_{Cl^-} reaches a maximum, $G_{Cl^-} = 1·38$, then falls, levelling off at a plateau value $G_{Cl^-} = 0·55$. At the higher temperatures of 100°, 185° and 210° C., the yield of chloride increases, but the later decrease is not observed.

The results may be interpreted in terms of the formation of a high-energy lattice defect structure produced by irradiation, which normally yields chlorate ion when the crystals are dissolved. How-

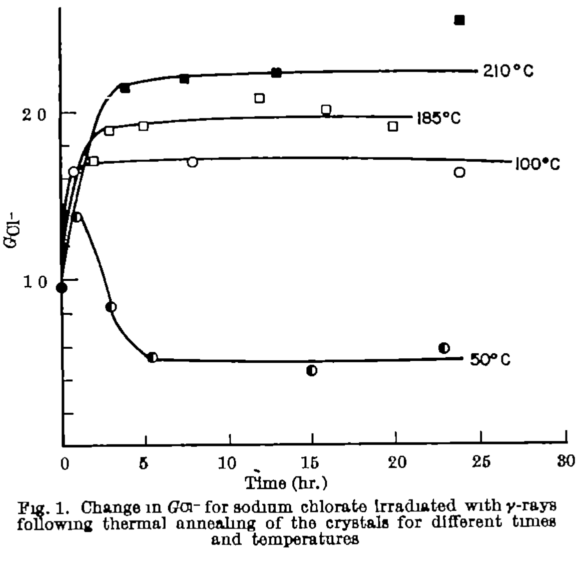

Fig. 1. Change in G_{Cl^-} for sodium chlorate irradiated with γ-rays following thermal annealing of the crystals for different times and temperatures

ever, when the solid is heated, sufficient energy is provided for the defect structure to decompose to chloride on heating. At 50° C. the later decrease in chloride is presumably due to recombination of chloride with the oxygen atoms to reform chlorate. At higher temperatures, this recombination is less complete, probably because of competing reactions such as diffusion of oxygen atoms away from the damage site or by combination of oxygen atoms to form oxygen molecules.

Electron Spin Resonance in γ-Irradiated Deoxyribonucleic Acid

DURING the past five years radiation-induced free radicals in deoxyribonucleic acid (DNA) have been the object of studies using electron spin resonance[1-5]. In particular, some work in this field was undertaken in our laboratory[6] with the main result that the yield of free radicals from γ-rays depends on the dose-rate.

The present communication summarizes some new results obtained using DNA from trout sperm which, irradiated in air at a temperature of 30° C. with γ-rays of cobalt-60, gave rise to a remarkable structure of the resonance line. The sample contained $0{\cdot}1$ per cent by weight of protein, approximately 20 per cent of water and a trace of sodium acetate. A conventional X-band electron spin resonance spectrometer with reflexion cavity was used. The external magnetic field was modulated at 416 c./s. and the first derivatives of the absorption curves were recorded after selective amplification and phase sensitive detection.

Fig. 1 shows a typical spectrum recorded 2 hr. after irradiation at a rate of 5×10^{5} r /hr. to a dose of 3×10^{7} r It consists of a central peak and two less-intense non-symmetrical side peaks. The central peak has a width at maximum slope of 10 œrsteds and its *G* value is $2{\cdot}003 \pm 0{\cdot}003$. The number of free radicals per gram measured from the total area under the curve is $3{\cdot}6 \times 10^{15}$. The radiation yield *G* is 2×10^{-4} as compared with 9×10^{-4} obtained previously by us[6] with commercial samples of DNA from herring sperm irradiated in air at the same rate. It should be mentioned that yields of 9×10^{-4} and 2×10^{-1} have been obtained with γ-rays by Blumenfeld[3] and Alexander[5] respectively on DNA's of different origins. However in these cases, the irradiations were performed *in vacuo* so that only doubtful comparisons may be drawn. We have indeed shown that the *G* values obtained even with identical samples of DNA from herring sperm irradiated by example at a rate of $2{\cdot}7 \times 10^{4}$ r./hr. to a dosage of 34×10^{6} r. are greatly affected by the external conditions[7] and are in fact much greater *in vacuo* (24×10^{-4}) than in air ($1{\cdot}9 \times 10^{-4}$).

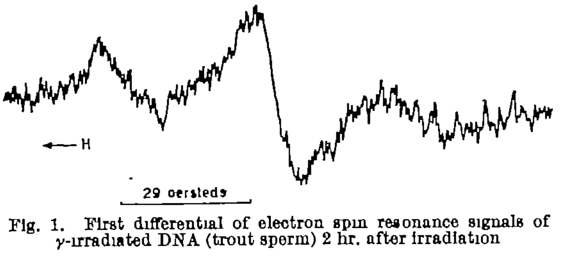

Fig. 1. First differential of electron spin resonance signals of γ-irradiated DNA (trout sperm) 2 hr. after irradiation

In the present experiments, both the shape and the intensity of the resonance line was found to vary with time. Four hours after the end of irradiation the central line was practically unchanged, though the heights of the derivatives of the side lines had decreased significantly. But, after 24 hr., the central line width had become 14 œrsteds whereas the side lines were so smeared out and the signal-to-noise was so bad that they could not be measured with any accuracy. In these conditions, the total number of unpaired spins may only be tentatively estimated as being 45 per cent less than in the initial state.

We thank Prof. J. Duchesne for helpful discussions, Prof. J. A. V. Butler and Dr. P. Alexander for samples of DNA, and the Centre d'Etude de l'Energie Nucléaire, Mol, for providing irradiation facilities.

CHEMISTRY

Catastrophic Failure of Stressed Polyethylene Terephthalate

IT has recently been reported[1] that nylon and 'Plexiglas' plates, if subjected to a bending stress in a vice, will give rise to catastrophic failure if the point of greatest tension is treated with a drop of some suitable liquid. It was concluded that the cohesive forces in the plane of greatest tensile strain collapse via the action of wetting and adsorption processes.

Similar behaviour occurs with amorphous polyethylene terephthalate sheet; but here a somewhat different mechanism for the cohesive breakdown is suggested.

If a strip of sheet (approximately $0{\cdot}1 \times 1 \times 5$ cm.) is given a bending stress by wrapping round a steel rod ($1{\cdot}5$ cm. diam.) and then held firmly in a vice, it will initially become opaque in the area of treatment with a spot of acetone, and ultimately fracture.

It has been shown[2,3] that a series of organic liquids will induce crystallization in amorphous polyethylene terephthalate, particularly if the solubility parameters of the liquids lie within a certain critical range. This process of crystallization is accompanied by an increase in opacity. It is therefore suggested that in the case of the stress-cracking described above, the acetone, or indeed presumably any liquid the solubility parameter of which lies within the permitted range, induces local crystallization. This creates a tendency to closer packing of polymer chains on the outer surface of the strip which sets up further stresses in addition to the already substantial bending stresses, which in turn may lead to fracture of the sample at the point of greatest tensile strain. Presumably the thicker the strip the more catastrophic will appear the breakdown. Although a similar explanation may be valid for certain nylons where some latent amorphous but potentially crystallizable material may exist, it is difficult to see how such an explanation would apply to an essentially amorphous polymer with no crystallization tendencies.

A Total Resolution of Aspartic Acid Copper Complex by Inoculation

RESOLUTION by inoculation of a supersaturated solution with one enantiomorph has been discussed by Greenstein[1]. More recently, the resolution of glutamic acid by inoculation has been perfected for industrial use[2,3].

Attempts in this laboratory to resolve aspartic acid by preferential inoculation have been unsuccessful, but a supersaturated solution of the copper complex prepared from the acetate[4] gave a virtually complete resolution in yields of 70–75 per cent of each of the optically pure aspartic acids. The mother liquor can be used for repeated resolutions.

DL-Aspartic acid (10·0 gm.) was dissolved in 750 ml. of 4 per cent acetic acid by warming at 60°. To this was added 16·0 gm. of Baker's cupric acetate monohydrate while warm and the resulting solution was filtered. When the filtrate cooled to approximately 50°, it was inoculated with about 2 mgm. pure L-aspartic acid copper complex. After the L-complex precipitated (precipitation was complete in a period of 10 min.–3 hr.) the crystals were filtered. This filtrate was inoculated with the pure D-complex and the precipitate of D-complex collected in the same way. By inoculation with alternate forms, successive crops were obtained. Six crops each of L-isomer and of D-isomer were obtained in a yield of 7·7 gm. total of L- and 7·6 gm. total of D-isomers.

To the mother liquor warmed to 60°, 10·0 gm. of DL-aspartic acid and 15·0 gm. cupric acetate were added; the resultant solution was filtered. From this supersaturated solution was obtained by seeding 8·3 gm. L-complex and 8·5 gm. D-complex. By addition of 19·5 gm. sodium hydroxide to the mother liquor, 1·57 gm. of L-complex and 1·66 gm. of D-complex were obtained. The total recovery of L-copper complex was 17·6 gm. (85 per cent) and 17·8 gm. (85 per cent) of D-complex.

The isolated copper complex salts were each recrystallized from 1·5 litre 3 per cent acetic acid containing 3·0 gm. cupric acetate. The recoveries were 14·2 and 14·1 gm. of L- and D-forms respectively. Each of these was dissolved in 1 N hydrochloric acid and the solution saturated with hydrogen sulphide. The aspartic acid isomers were isolated by adjusting a 200-ml. volume of aqueous solution to pH 3. Thus was obtained 7·4 gm. (74 per cent) L-aspartic acid and 7·4 gm. (74 per cent) D-aspartic acid The respective $[\alpha]_D^{26}$ values in 6 N hydrochloric acid were $+ 24{\cdot}4° \pm 0{\cdot}0°$ and $- 24{\cdot}6° \pm 0{\cdot}0°$. Nitrogen analyses agreed with the theoretical value.

Although the copper salt may be an unlikely kind of material for spontaneous resolutions in the primordial era, the result obtained illustrates in principle processes of a type which may have contributed to the origin of optical activity on the primitive Earth. Many plausible explanations for the origin of optical activity are now at hand[5-12]. The demonstration with the copper complex suggests that the chance crystallization of one enantiomorph of a key biochemical substance could trigger sequences of reactions favouring one optical type in those compounds having an asymmetric carbon atom. (In a personal communication, Dr. Henry Gilman has pointed out that chemists who might observe spontaneous resolution would be loathe to report such observation, much as explained by him some years ago[13].)

Thin-Layer Chromatography of Nucleotides on Layers of Cellulose Ion-Exchangers

As has recently been shown[1], thin-layer chromatography[2] on ECTEOLA cellulose layers is a rapid and simple method for separating nucleic acid derivatives.

Improved and standardized cellulose ion-exchangers for thin-layer chromatography are now obtainable (Serva-Entwicklungslabor, Heidelberg, Germany). These materials have a low substitution grade and are prepared from a special wood cellulose. On these layers the complete separation of nucleoside diphosphates (for example, ADP) from their corresponding triphosphates (for example, ATP) can be achieved within 5–10 min. The separation of CTP, ATP, GTP and UTP requires 60–100 min.

Preparation of ECTEOLA and DEAE cellulose layers: A slurry is made by mixing 10 gm of the ion-exchanger powder with 60–70 ml. distilled water and shaking vigorously for 30–45 sec. The suspension obtained is spread in the usual way[2] over the glass plates, which must be thoroughly clean. (Previous treatment with a detergent, followed by water, is recommended.) 7–10 plates, size 10 × 20 cm., are obtained. The layers are allowed to dry overnight at room temperature.

Table 1. R_F VALUES OF NUCLEOSIDE DI- AND TRI-PHOSPHATES

Compound	Solvent 0·02 *N* HCl	 0·03 *N* HCl	 0·04 *N* HCl
ADP	0·48	0·68	
ATP	0·11	0·20	0·56
GDP	0·27	0·51	
GTP	0·07	0·14	0·41
CDP	0·53		
CTP	0·18	0·31	0·64
UDP	0·15	0·25	
UTP	0·04	0·08	0·18

Solutions of nucleotides (in general 10^{-3}–10^{-1} µmole of each compound) are applied from a pointed micropipette (10 µl.) at a line 3·0 cm. from the edge of the plate. The plates are placed in an open beaker filled with an appropriate solvent to a height of about 1·2 cm. A covered jar is not necessary. The chromatography can be observed by means of a short-wave ultra-violet lamp. It is stopped after the solvent has travelled an appropriate distance. The chromatograms can be traced on 'Cellophane' sheets under an ultra-violet lamp.

For many separations dilute hydrochloric acid is a sufficient solvent. Table 1 lists the R_F values of ribonucleoside di- and tri-phosphates obtained on DEAE cellulose layers. ATP, GTP and UTP or CTP, GTP and UTP can be completely separated with 0·04 *N* hydrochloric acid. ATP and CTP, however, are only partially resolved. These compounds can be separated by chromatography with 0·1 *M* sodium chloride on the DEAE cellulose layer.

The differences of the R_F values of the corresponding di- and tri-phosphates are very remarkable. As a consequence of this, analytical quantities of these compounds (10^{-3} µmole) can be completely separated on ECTEOLA or DEAE cellulose layers within 5–10 min. These layers might also be useful for the chromatography of oligonucleotides, polynucleotides and proteins.

Melting Point of *p*-Bromophenacyl Formate

THE recent note by Crosbie[1] has given the melting point of *p*-bromophenacyl formate as 98°. This is in good agreement with the melting points of 99° and 99–100° given by Grove and Suter[2], and Kubota and Matsuura[3] respectively. Attention is directed to these two earlier papers[2,3] which were overlooked by Neish and Lemieux[4] and have not been mentioned directly by Crosbie[1]. A sample of *p*-bromophenacyl formate (m.p. 99°) was sent to me by Dr. Grove. A mixture of this with our sample (m.p. 92°) melted in an intermediate range. It was concluded that our sample was impure and the true melting point of this compound is about 99°.

BIOCHEMISTRY

Structure of Ferroverdin

IN a previous communication from this laboratory the purification and preliminary characterization of ferroverdin, a green iron-containing pigment with formula $C_{30}H_{24}FeN_2O_8$ produced by a new *Streptomyces* species, were reported[1]. The iron atom was shown by magnetic measurements to be bound in the divalent form[2].

Chemical investigations, to be briefly described in the present communication, show that ferroverdin is built up of two identical C_{15} moieties held together by iron, each being the *p*-vinylphenylester of 3-nitroso-4-hydroxybenzoic acid. The previously reported formula for ferroverdin must therefore be replaced by $C_{30}H_{20}FeN_2O_8$, which is in good agreement with new elementary analyses made on a thoroughly dried crystalline sample (found: C, 59·07, 59·16, H, 3·52, 3·71; Fe, 9·07; N, 4·26, 4·62; calc. for $C_{30}H_{20}FeN_2O_8$ - $1H_2O$: C, 59·03; H, 3·63; Fe, 9·15; N, 4·59).

As mentioned previously, ferroverdin is readily reduced by hydrogen in the presence of a palladium catalyst. The iron-free compound so formed has been converted into a crystalline triacetyl-derivative, which can also be obtained by reductive acetylation of ferroverdin with zinc, followed by catalytic hydrogenation on a palladium catalyst. It melts at 125°–7° C. and gives analytical results in good agreement with the formula $C_{21}H_{21}NO_6$ (found: C, 65·95, 65·66; H, 5·86, 5·49; N, 3·69, 3·72; CH_3–C, 28·22, 28·35; mol. wt. 335,337; calculated: C, 65·78; H, 5·52; N, 3·65; $4CH_3$–C, 28·20; mol. wt., 383).

Its ultra-violet spectrum in 55 per cent ethanolic solution shows a single maximum at 238 mµ (ε = 18,500) and an inflexion at 270 mµ (ε = 4,000); on addition of alkali two maxima appear at 250 mµ (ε = 19,100) and 314 mµ (ε = 28,600), which are shifted to 243 and 288 mµ respectively when the solution is kept for 27 hr. at room temperature.

The infra-red spectrum (in potassium bromide disk) shows strong bands for *O*-acetyl (1,770 cm.$^{-1}$), *N*-diacetyl and ester (1,720 cm.$^{-1}$, broad) groups. The nuclear magnetic resonance spectrum obtained with a $CDCl_3$ solution (at 60 Mc./sec.; τ-values relative to tetramethylsilane as internal standard) clearly indicates an ethyl group attached to an aromatic ring (quadruplet centred at 7·31 τ, and triplet centred at 8·74 τ) and three acetyl groups (7·65 τ, partially resolved into two peaks).

By working up a 1 *N* aqueous methanolic sodium hydroxide solution of this triacetyl compound kept for 27 hr. at room temperature, two known substances have been isolated, namely, *p*-ethylphenol in 91 per cent yield, and 3-acetylamino-4-hydroxybenzoic acid in 64 per cent yield. Acid hydrolysis (6 *N* hydrochloric acid, 3 hr. at 100° C.) of the same compound gave *p*-ethylphenol and 3-amino-4-hydroxybenzoic acid in more than 90 per cent yield.

A compound with chemical and physical properties identical with those of the above triacetyl compound was synthesized by reacting *p*-ethylphenol with 3-acetylamino-4-acetoxybenzoyl chloride, followed by further acetylation with acetic anhydride and sodium acetate, thus proving its structure as the *p*-ethylphenylester of 3-diacetylamino-4-acetoxybenzoic acid. Elementary analysis, ultra-violet, and nuclear magnetic resonance spectra of the compound obtained by reductive acetylation of ferroverdin, without further catalytic hydrogenation, clearly showed it to have the formula $C_{11}H_9NO_6$ and to contain a vinyl substituent in place of the ethyl substituent found in the fully reduced triacetyl compound. Alkaline degradation of the vinyl substituted triacetyl compound gave again 3-acetylamino-4-hydroxybenzoic acid; but *p*-vinylphenol instead of *p*-ethylphenol was formed, thus suggesting that the compound is the *p*-vinylphenylester of 3-diacetylamino-4-acetoxybenzoic acid.

As in the case of the two triacetylated compounds referred to here, ferroverdin undergoes a rapid spectral change in the ultra-violet in alkaline solution though its green colour is retained. From the alkaline solution *p*-vinylphenol and a green iron-containing acid were isolated. The latter was shown to be identical by infra-red, ultra-violet and visible spectrum, paper chromatography and paper electrophoresis with the ferrous complex of 3-nitroso-4-hydroxybenzoic acid, synthesized by mild alkaline hydrolysis of the corresponding methylester, which in turn was synthesized from the methylester of 4-hydroxybenzoic acid by the method of Cronheim[3]. The methylester of the green iron-containing product of mild alkaline hydrolysis of ferroverdin was also shown by the same methods to be identical with the synthetic methylester.

It is well known that iron forms deep green co-ordination compounds with *o*-nitrosophenols[3,4].

The exact configuration of the iron complex has yet to be elucidated; several possibilities exist, including that involving the quinone-oxime tautomer and the nitroso dimer.

Ferroverdin is a new member of the rapidly growing group of natural iron-containing compounds, but unique in its structure as an *o*-nitrosophenol; it would, in fact, appear to be the first *C*-nitroso compound encountered in nature.

We thank Prof. K. Wiesner and Prof. L. Paoloni for valuable discussions. We also thank Prof. K. Wiesner for providing us with the nuclear magnetic resonance spectra.

The ferroverdin used for this work was produced in the fermentation pilot plant of this Department under the supervision of Dr. A. Tonolo.

Inhibition of Hyaluronidase by Urinary Kallikrein

INVESTIGATIONS have shown that crude kallikrein prepared from human urine and human serum possesses *in vivo* spreading properties which cannot be attributed to hyaluronidase activity[1-3]. Turbidimetric[4], mucin clot[5] and viscosimetric[6] procedures reveal that urinary kallikrein unlike hyaluronidase does not depolymerize hyaluronic acid. On the contrary, a marked inhibition of testicular hyaluronidase occurs when kallikrein is combined with the enzyme. In order to define further the properties of kallikrein, we investigated *in vitro* the effect of a urinary preparation on hyaluronidase.

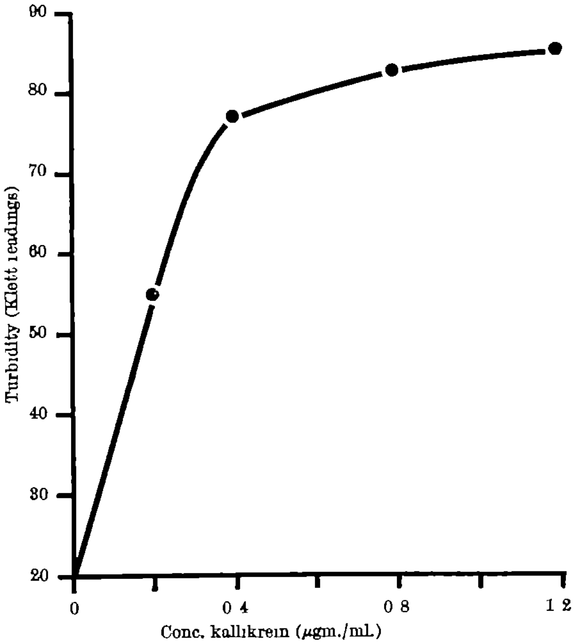

Fig. 1. Inhibition of hyaluronidase by various concentrations of kallikrein

The hyaluronidase-inhibiting properties of a crude preparation of human kallikrein was assayed turbidimetrically. Several dilutions of inhibitor were prepared in volumes of 0·4 ml. in 0·1 *M* acetate buffer at *p*H 6. Substrate for the system consisted of partially purified bovine testicular hyaluronidase (691 U.S.P. units/mgm.) and purified vitreous humour potassium hyaluronate. The solution of enzyme in 0·1 *M* acetate buffer at *p*H 6 was added in a volume of 0·2 ml. The tubes were shaken in a rack and then incubated at room temperature for 30 min. Residual hyaluronidase activity which remained after incubation of the inhibitor dilution and hyaluronidase mixture was determined as follows: To each tube was added 0·4 ml. of potassium hyaluronate (0·15 mgm.) dissolved in 0·1 *M* acetate buffer (*p*H 6) and sodium chloride to a molarity of 0·05. The tubes were incubated in a water bath at 37° C. for 30 min. To each tube 4 ml. of a 1 : 40 dilution of horse serum (*p*H 3·1) was added. After another 30 min. incubation at room temperature, the turbidity of the mixture was determined in a Klett-Summerson colorimeter using a No. 66 filter.

The potency of kallikrein as an inhibitor is determined in terms of decrease or loss of hyaluronidase activity. By comparing the turbidity produced by the enzyme-inhibitor-substrate mixture to that of inhibitor-substrate control a linear relationship is demonstrated between the concentration of the enzyme and depolymerization of substrate. Loss of activity due to the presence of inhibitor is expressed as percentage reduction in enzyme activity. No effect on the turbidity of substrate occurs within the range of kallikrein concentrations used when no hyaluronidase is present.

Fig. 1 shows the effect of various concentrations of kallikrein on the activity of 2·5 μgm./ml. hyaluronidase. This demonstrates that the inhibition of hyaluronidase occurs rapidly with the first small increments of kallikrein and reaches a maximum at

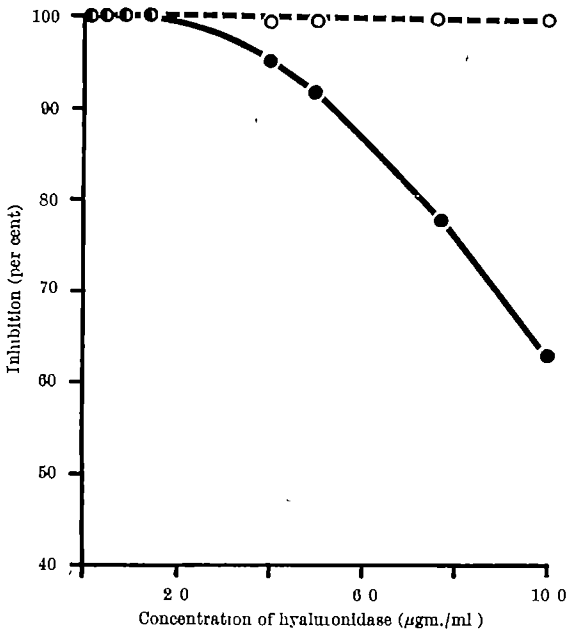

Fig. 2. Effect of kallikrein on the depolymerization of potassium hyaluronate by hyaluronidase; ●, 2 μgm./ml kallikrein, ○, 20 μgm./ml. kallikrein

1·2 μgm./ml. Confirmation is readily obtained by both the mucin clot prevention test and viscosimetric procedures. The curves in Fig. 2 show the extent of depolymerization of a constant amount of substrate by 2 and 20 μgm./ml. inhibitor. Thus, as the hyaluronidase concentration increases, the inhibition by small amount of kallikrein decreases. Large amounts such as demonstrated by 20 μgm./ml. kallikrein are completely inhibitory.

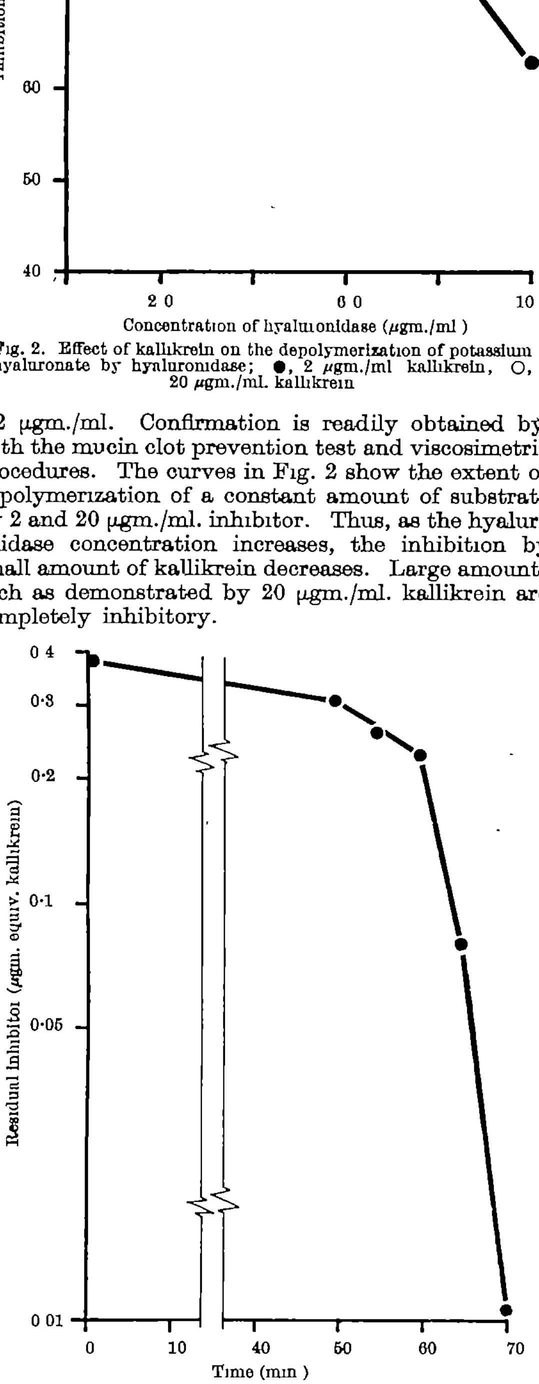

Fig. 3 Rate of inactivation of antihyaluronidase activity of kallikrein as a result of exposure to ultra-violet light

The inactivation of kallikrein by ultra-violet light was demonstrated by Werle[7]. This reaction is therefore one of the characteristic properties of the material. In order to determine that the results we obtained are due to kallikrein 0·1 μgm./ml. kallikrein was exposed to a Westinghouse $G15T8$ ultra-violet bulb at a distance of 5 in. The inactivation as measured by the rate of destruction of hyaluronidase inhibitory activity is shown in Fig. 3 and confirms, in part, our initial assumption.

Although kallikrein is found in urine, blood and certain organs and glands, its biological role is obscure. It has been suggested that kallikrein circulates in the blood in an inactive form and may be activated by disease or changes in blood *p*H. Recently Ginetzinsky and Berlyne[8] demonstrated a relationship between urinary hyaluronidase and various diuretic conditions. Our results suggest that the hyaluronidase-inhibitory properties of kallikrein may have significance from the standpoint of regulating the activity of this enzyme *in vivo*. Since no one has been able to obtain a purified kallikrein, the spreading activity as described by Christensen is most likely due to unspecific factors.

We thank Drs. M. E. Webster and J. V. Pierce, National Heart Institute, Bethesda, Md., for the sample of human urinary kallikrein (6 Frey units/mgm.).

Separation of Lecithin and Phosphatidyl Ethanolamine by Chromatography on Paper impregnated with Zinc Salts

THE separation of phospholipids by paper chromatography has generally been performed on modified papers. Marinetti and Stotz[1] and Lea *et al.*[2] report the use of silicic acid-impregnated paper, and Brown *et al.*[3] have used silicic acid-impregnated glass-fibre 'paper'. Rouser *et al.*[4] investigated the possibility of using paper impregnated with mineral oil, rubber, silicone, and formamide, and paper oxidized by periodic acid, but found all these to be unsuitable. Recently, however, in this laboratory[5] a method has been evolved for the separation and differential staining of phospholipids on untreated paper. During work on this method difficulty was encountered with the separation of lecithin from phosphatidyl ethanolamine, and a procedure for separating them on paper impregnated with zinc salts is described here.

Since cadmium chloride forms a complex more readily with lecithin than with phosphatidyl ethanolamine the use of this salt during chromatography was examined. Formation of the phospholipid–cadmium chloride complex in a solution of lecithin and phosphatidyl ethanolamine, followed by application of the solution to Whatman No. 1 paper, and chromatography in di-*n*-butyl ether/propionic acid (4 : 3 v/v)

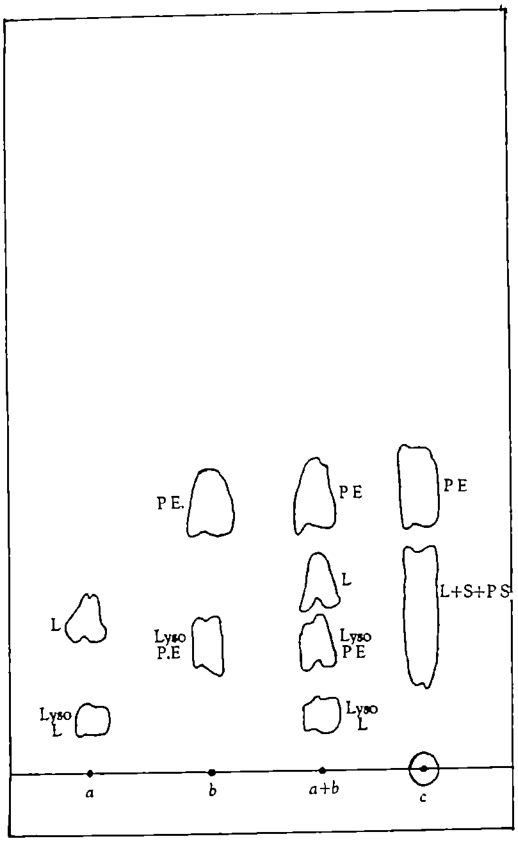

Fig. 1. Line drawing of ascending one-dimensional chromatogram impregnated with zinc salts, and run in di-*n*-butyl ether/propionic acid (2 . 1 v/v) saturated with zinc chloride. *a*, Sample of lecithin; *b*, sample of phosphatidyl ethanolamine, *c*, extract of liver of mouse (ref. 6). L, Lecithin, P.E., phosphatidyl ethanolamine; lysoL, lysolecithin; lysoP.E., lysophosphatidyl ethanolamine; S, sphingomyelin; and P.S., phosphatidyl serine

saturated with water (a solvent system suitable for phospholipids), was unsuccessful, since the acid solvent disrupted the complex. Formation of the complex on the paper after application of the lipids, by soaking it in an aqueous solution of cadmium chloride, washing out of excess cadmium chloride, and drying, did not give separation after chromatography. If, however, the paper was not washed after soaking in the cadmium chloride solution but merely dried so that the paper was impregnated with cadmium chloride, which acted as an adsorbant, some small separation was achieved. It was also necessary to saturate the solvent system with cadmium chloride.

Salts of aluminium, magnesium, barium, and zinc were also investigated. Of these, zinc chloride gave the best separation of lecithin and phosphatidyl ethanolamine. A solvent system without water was found to be most efficient: di-*n*-butyl ether/propionic acid (2 : 1 v/v) saturated with zinc chloride (B.D.H., fused) was used. There was some difficulty with zinc chloride impregnation of the paper, since in solution this salt is a cellulose solvent, and variation was found between different batches of zinc chloride. This was overcome by the use of a solution of zinc oxide in a 3·5 per cent aqueous solution of hydrochloric acid (a 10 per cent solution of concentrated hydrochloric acid, sp. gr. 1·18, in water). The acid solution was saturated with zinc oxide at about 60° C., allowed to cool to room temperature, and filtered. It seems likely that under these conditions of excess oxide and weak acid, followed by evaporation to dryness, the oxychlorides would also be formed. Zinc chloride forms several hydrates, and the paper is thus impregnated by a zinc chloride–zinc oxychloride–hydrate system. Since the solvent does not contain water the usual partition of the phospholipids between water and the organic solvents is impossible, and separation must therefore be effected by differential adsorption.

The procedure for the separation of lecithin from phosphatidyl ethanolamine is as follows: (1) The phospholipids (about 40 μgm.) are applied to the base of the paper (Whatman No. 1). (2) The paper is soaked in a solution of zinc oxide in 3·5 per cent hydrochloric acid for 5 min. (Steps 1 and 2 may be reversed.) (3) The paper is removed from the solution, laid momentarily on dry filter paper, and dried under a stream of hot air. If some of the excess solution is not blotted off the paper the values R_F are increased and separation improves. However, the distribution of the zinc salts is usually uneven: it is therefore better to lay the paper on dry filter paper for two or three seconds before drying it. (4) The paper is chromatographed by the ascending method in di-*n*-butyl ether/propionic acid (2 : 1 v/v) saturated with zinc chloride. The solvent travels about 27 cm. in 4 hr. (5) The paper is then dried under a stream of hot air and stained by the 'Solochrome' technique for phospholipids[5].

It was found that this technique also separated lysolecithin from lysophosphatidyl ethanolamine: from a mixture of partially lysed lecithin and partially lysed phosphatidyl ethanolamine four spots were obtained—phosphatidyl ethanolamine, lecithin, lysophosphatidyl ethanolamine, and lysolecithin (Table 1). Lecithin and phosphatidyl ethanolamine can be separated not only from an artificial mixture but also from a tissue extract (Fig. 1).

Table 1

Phospholipid	R_F value
Phosphatidyl enthanolamine	0 32–0·40
Lecithin	0 20–0·25
Lysophosphatidyl ethanolamine	0 13–0·18
Lysolecithin	0 05–0 08

This method has, as yet, been applied only to the separation of lecithin and phosphatidyl ethanolamine, and the separation of other phospholipids by impregnation of the paper with inorganic salts has not been studied. It seems likely, however, that by the choice of suitable inorganic compounds, other than the troublesome and unreproducible silicic acid, and by the use of appropriate solvent systems all phospholipids could be separated. The use of paper impregnated with inorganic salts for the separation of organic compounds seems to have been a neglected aspect of chromatography and should repay further investigation.

L-Glutamate Dehydrogenase Isoenzymes

SEVERAL dehydrogenases have been resolved into isoenzymes by electrophoresis in starch gel. Attempts to fractionate L-glutamate dehydrogenase in this way, however, have so far failed. Markert and Moller[1] found that this enzyme was electrophoretically immobile in starch gel, and Tsao[2] obtained negative results in attempts to fractionate and render glutamate dehydrogenase visible.

Using a technique developed for determination of lactate dehydrogenase isoenzymes in clinical routine[3,4], however, it proved possible to demonstrate multiple forms of glutamate dehydrogenase in homogenates of human organs.

Fractionation was effected by electrophoresis in agar gel, and the dehydrogenase activity was made visible by incubation of the gel in a solution containing sodium glutamate, diphosphopyridine nucleotide, phenazine methosulphate and a tetrazolium salt.

Human tissues were obtained by autopsy less than 12 hr. after death. The tissues were stored at − 20° C. for one night. Tissue extracts were prepared by homogenizing 1 gm. of tissue with 1 ml water by means of a motor-driven Potter–Elvehjem tissue grinder. The extracts were clarified by centrifugation. Electrophoresis was carried out with 8 μl. of the extract, using the technique on microscope slides of Wieme[5]. The slide was then incubated for 1 hr. at 37° C. in the following medium: sodium-DL-glutamate (M) adjusted to pH 7·4 (1 ml.); diphosphopyridine nucleotide (10 mgm./ml.) (1 ml.); sodium cyanide (0·1 M) (1 ml.); phosphate buffer (0·5 M, pH 7·4) (2·5 ml.); nitroblue-tetrazolium (1 mgm./ml.) (2·5 ml.); phenazine methosulphate (1 mgm /ml.) (0·25 ml.).

At the sites of dehydrogenase activity purple deposits of formazan are formed during incubation. When glutamate is omitted from the incubation fluid, no formazan bands are formed. After incubation the slide is washed with water and, if desired, densitometry can be carried out with the wet slide. The proteins can also be fixed in the following fluid: ethanol 70 vol., acetic acid 5 vol., distilled water up to 100 vol. The plate on which the protein fractions become visible during fixation is afterwards dried while covered by filter paper. Densitometry can then be carried out on the dry plate. The slides must be stored protected from daylight; in the light, a background slowly develops. The distance between human albumin and dextran, run on the same plate, was taken as unit of measurement for the determination of relative mobilities.

The result obtained by this technique with an extract of human heart muscle is shown in Fig. 1. Five glutamate dehydrogenase fractions are visible, and some activity is retained in the application slit. The results of electrophoretic separation of glutamate dehydrogenase isoenzymes of other tissues are given in Table 1. A total of six isoenzymes has been found. Also it appears that there are differences in the isoenzyme contents of the different tissues.

Heat-Coagulation of Edestin

PROTEINS in aqueous solution are denatured by heating; few separate proteins resist the temperature of boiling water for more than a few minutes. It is therefore surprising to find that under certain conditions a protein molecule as large as that of edestin can be heated for a long time at 100° C. without causing any change. This was observed during experiments being carried out to establish the best conditions for complete heat-coagulation of edestin.

For this purpose we selected conditions similar to those used by M. and S. P. L. Sørensen[1] for the heat-coagulation of ovalbumin, namely, an acidity very near the isoelectric point and a high ionic strength (1/3 saturated sodium sulphate). The isoelectric point of edestin being unknown, it was necessary to establish the optimal pH under the conditions which were as follows: to one volume of a solution in 10 per cent sodium chloride and 0·1 M sodium bicarbonate of a carefully purified edestin was added one volume of a buffer mixture and one of a saturated solution of sodium sulphate. The mixture was heated in a boiling water bath (98° C.) for 20 min. and filtered hot on steam-heated funnels. The amount of uncoagulated protein in the filtrate was determined by the Kjeldahl procedure. Measurements of pH were made at room temperature before heating.

The results (Fig. 1) show that coagulation is practically complete at pH 4·6 and lower. It may be remarked that at these low pH values the protein precipitates before heating. Only an insignificant amount of clot is formed at pH 5·8–7·8, 95 per cent or more remaining in solution. At higher pH values partial coagulation occurs with a maximum around pH 10.

The interesting pH-range is that where practically no coagulation occurs. At first, we thought that denaturation did occur but that coagulation had been prevented by the high temperature. Cooling of the filtrates did show indeed the formation of a precipitate, but only at pH values of less than 6·3, as indicated by the broken curve in Fig. 1. It is interesting to note that at pH 5·5 the protein is soluble when heated but precipitates when cooled, and this may be repeated at will, imitating the behaviour of Bence-Jones protein.

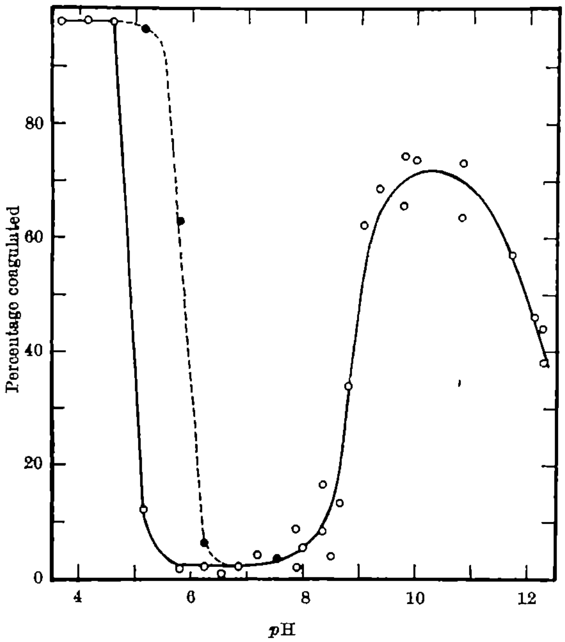

Fig. 1. Heat coagulation of edestin. Full line and open circles, filtered hot; broken line and black circles, filtered after cooling

Between pH 6·3 and 7·8, there is a small region where no coagulation could be observed by heating and no precipitate appeared by cooling afterwards. In order to decide if, at this critical range, the protein had undergone denaturation or not, a large sample of edestin was heated for 20 min. under the same conditions as described, at pH 6·3. This solution was submitted to the following tests. Light-scattering revealed the same molecular weight as the original (338,000). There was no increase in the light-scattering after two days, indicating absence of any slow aggregation or tendency to coagulate. The ultraviolet absorption spectrum was quantitatively identical with the spectrum of the unheated solution. After precipitation by half-saturation with ammonium sulphate, the protein again dissolved in 10 per cent sodium chloride and 0·1 M sodium bicarbonate, giving a perfectly clear solution. Finally, by dialysis against a phosphate buffer at pH 7·0 (Sørensen) crystals were formed identical with those of the original protein.

These observations show, at the short pH-range 6·3–7·8, edestin was not denatured by heating at 100° C. for 20 min. and perhaps even longer, since after 40 and even 60 min. no clot was formed.

This unexpected resistance to heat denaturation of edestin in a short pH-range suggests that denaturation is only possible through the exchange of protons. According to this hypothesis, heat, as such, is not a denaturing agent but a factor influencing the proton exchange reaction.

Presence of Indole Compound in Nematode Galls

Multi-nucleate structures or giant cells in plants infected by root-knot nematodes are believed to arise in response to substances emanating from the parasite[1]. DuCharme[2] stated that the resulting tumours and galls are due to reactions of the host plant and might be considered as a kind of defence mechanism. According to him, growth-stimulating substances, presumably released by the nematodes, lead to hyperplasia of the pericycle and root tip in citrus. Krusberg[3] found that tryptophan, the precursor of indole, is present in the nematodes infected or nematode-free callus tissues and also in the galls caused by *Ditylenchus dipsaci* (Kuhn) Filipjev on alfalfa roots. According to Goodey[4], Wallace suggested that formation of giant cells in roots attacked by *Heterodera* spp. and *Meloidogyne* spp. might possibly be due to the presence of growth hormones. The experiment reported here was undertaken to examine whether any indole compound is present in the galled tissues of nematode-infected plants.

Meloidogyne javanica (Trueb) Chitwood, isolated from tomato root galls, was inoculated into healthy roots of *Abelmoschus esculentus* Moench, grown in sterilized soil, following the method used in the previous studies in this laboratory[5] and the root galls were obtained after 45 days. The roots were washed thoroughly in running water and then in sterilized water and examined for the presence of indole compounds. 25 gm. of galled tissues were removed from the roots and kept in a refrigerator at 8° C. for 24 hr. Healthy roots of the same age from uninoculated control plants were also prepared in a similar manner. The frozen roots were macerated separately and extracted with ether, using 5 ml./gm. of the tissue. The extracts were assayed chromatographically following the method recommended by Wright[6]. Known samples of indolyl-3-acetic acid (IAA) and indolyl butyric acid (IBA) and samples of the extracts from the galls and healthy roots were spotted on circular chromatographic paper (Whatman No. 1)

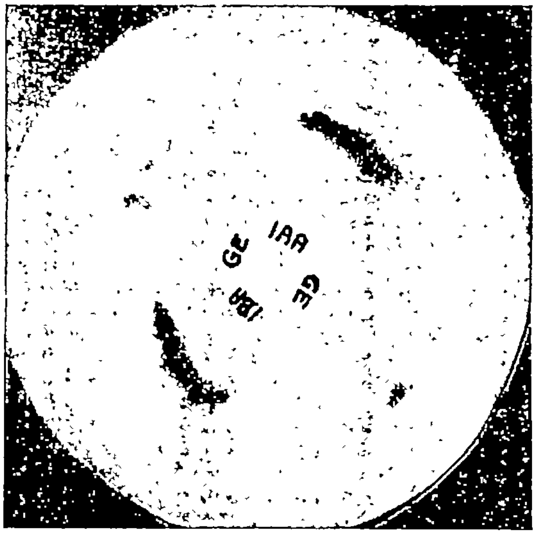

Fig. 1. Circular chromatogram run with ether extracts of nematode root galls of *Abelmoschus esculentus*, developed in butanol/ammonia/water (100 100 · 8), at 28°–29° C. in complete darkness and differentiated with Salkowski reagent. IAA, Indolyl-3-acetic acid; IBA, indolylbutyric acid; GE, gall extract

and developed with butanol/ammonia/water (100 : 100 : 8) at room temperature (28°–29° C.) in complete darkness for 12 hr. Salkowski reagent was used to differentiate the indole compounds on the paper. The extract from the gall and the known IAA gave spots with similar R_F values (0·56) and pink colour, the colour in the latter case being more intense (Fig. 1). Both spots were ash coloured when viewed through ultra-violet light. According to Sen and Leopold[7] the pink colour in daylight and ash colour in ultra-violet light of the spots indicate IAA. IBA gave a brown spot with an R_F of 0·42 (Fig. 1). No spots developed when the extract from healthy roots was similarly assayed. These chromatographic studies were repeated several times and the same results were obtained each time. Thus there are indications of the presence of an indole compound in the extracts of galled tissues of *A. esculentus*. It is quite probable that the compound plays a part in gall formation.

Tryptophan and Indole Compounds in Banana Ovaries

THE ovary of an edible banana, *Musa paradisiaca* Linn., develops into a vegetatively parthenocarpic fruit and at maturity is filled with starchy parenchymatous tissues. Simmonds[1] reported the autonomous production of auxin, suspected as being indolyl-3-acetic acid (IAA), in the young ovaries of banana. The presence of 'coconut milk factor' in the banana ovaries has also been reported[2,3]. The results reported here are from investigations carried out in this laboratory during 1960–61 on the type of auxin and amino-acids present in the ovaries of banana.

A popular culinary banana variety, Monthan, was selected for the purpose. The ovaries were obtained from the hearts of bananas cultivated in the Annamalai University Experimental Farm. The methods of extraction of the ovaries and chromatographic differentiations to detect the auxins were the same as those described by Wright[4]. Extracts of ovaries at emergence, 48 hr. after emergence and later at weekly intervals, were taken and assayed chromatographically to detect indole compounds. Ascending chromatograms were run for 12 hr. in complete darkness at room temperature (28°–29° C.) with Whatman No. 1 paper strips, using butanol/ammonia/water (100 : 100 : 8) as the medium. Salkowski reagent was sprayed on the chromatograms to differentiate the spots.

In Fig. 1 is shown a comparison of the spots developed in the ascending chromatogram run with the extract of ovaries taken at the emergence of the inflorescence (1) and 48 hr. after emergence (2) with a sample of IAA (British Drug House, Bombay). The spots developed with the first extract were orange with a red tinge in daylight and green in ultra-violet light, with an R_F of 0·61, whereas there were two spots from the second extract, one pink coloured with an R_F of 0·23 and the other orange with red tinge with an R_F of 0·60, the latter turning pale green in the ultra-violet light. The two spots obtained with the known IAA were almost similar to those obtained with the second extract. According to Sen and Leopold[5], the orange spots with red tinge obtained with this chromatographic system refer to indole compounds. In the present investigations the orange spots with red tinge and an R_F of 0·60–0·61 obtained with the first and second extracts would seem to represent an indole compound similar to IAA.

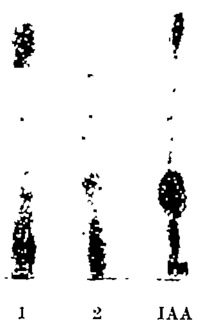

Fig. 1

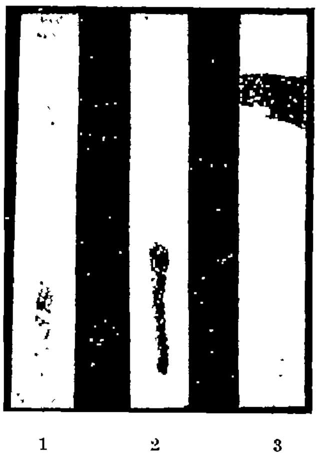

Fig. 2

Fig. 1. Ascending chromatogram of banana ovary extracts at emergence (1) and 48 hr. after emergence (2) as compared with known IAA

Fig. 2. Ascending chromatogram of banana ovary extracts at emergence (1), as compared with known tryptophan (2) and the extract of three-week-old ovaries (3)

When the ovaries were extracted 8 and 15 days after emergence and assayed chromatographically for indole compounds, the characteristic orange with red tinge spots of indole compounds were found and these spots turned pale green in ultra-violet light. Their R_F value was, however, 0·84 as compared with 0·61 for the spots from the extracts obtained from the ovaries at the early stages of development. The extract of three-week-old ovaries when spotted on chromatogram showed a green spot with bluish tinge and an R_F of 0·82 (Figs. 2–3). This spot resembled that of indolyl acetonitrile (IAN), which according to

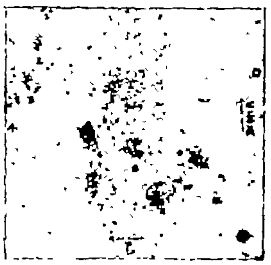

Fig 3

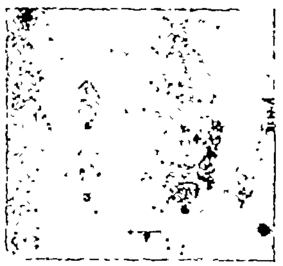

Fig 4

Fig. 3. Two-dimensional chromatogram showing the amino-acids in the extracts of ovaries at the time of emergence. leucine (1), valine (2), methionine (3), proline (4), tryptophan (5), alanine (6), histidine (7), threonine (8), glutamic acid (9), serine (10), hydroxy-proline (11) and aspartic acid (12)

Fig. 4. Two-dimensional chromatogram showing the amino-acids in the extracts of ovaries 48 hr. after emergence leucine (1) alanine (2), histidine (3), glutamic acid (4), serine (5), hydroxy-proline (6) and aspartic acid (7)

Sen and Leopold[5] turned greenish-blue in ultra-violet light. Jones *et al.*[6] discovered the presence of IAN in cabbage leaves which, according to them, was more active than IAA. It is probable that the IAN-like compound in the later stages of development of the banana ovary has a similar activity.

When the ether extract of the ovary at the time of emergence of the inflorescence was assayed chromatographically for the presence of indole compounds, indications for the presence of a tryptophan-like compound were obtained. In Fig. 2 is shown a comparison of the known tryptophan (2) with an R_F of 0·37 and the unknown (1) with an R_F of 0·40 from the extract of the ovaries. It seemed advisable, therefore, to examine the extracts for the presence of amino-acids. When the ovaries were extracted in a similar manner as described above and two-dimensional chromatograms run to detect the presence of amino-acids, on applying the method recommended by Giri and Rao[7] (using butanol/acetic acid/water (4 : 1 : 1) and phenol as solvents and ninhydrin as the colour-developing reagent) indications of the presence of 12 amino-acids, inclusive of tryptophan, were obtained in the extracts of ovaries at the time of the emergence of the inflorescence (Fig. 3), whereas in the extracts obtained 48 hr. after emergence indications for only 7 amino-acids were apparent and tryptophan could not be detected (Fig. 4). Perhaps the presence of tryptophan in the early stages indicates that it is a precursor of the IAA-like substance in the ovaries.

According to Simmonds[8], in bananas, as in other plants, two systems of stimuli are responsible for initiating and maintaining fruit development. It is also possible that the IAA and IAN-like compounds observed in the present investigation are the factors involved and the pathway of their biosynthesis is by means of tryptophan.

PHYSIOLOGY

Afferent Cutaneous C-fibre Reactivity to Repeated Thermal Stimuli

SINGLE afferent *C*-fibres from the skin of the rat's tail were isolated by the method described by Hensel, Iggo and Witt[1]. These fibres were non-specific; activity was recorded in them both to mechanical and strong thermal stimuli applied to the skin. There was in this respect a strong similarity between these fibres and a few *C*-fibres in the cat's skin described by Iruichijima and Zotterman[2] which responded to mechanical stimuli, to heating the skin above 50° C. and to cooling the skin below 10° C. Non-specific fibres responding to all kinds of noxious and non-noxious thermal and mechanical stimuli have been found recently by Witt[3] and fibres, responding to extreme thermal stimuli only by Iggo[4]. It has been suggested[2-4] that these fibres might have a "nociceptive function". The present investigations, which concern the behaviour of non-specific *C*-fibres to repeated stimulation, would appear to confirm the suggested "nociceptive function" of these afferents.

Identical thermal stimuli were repeatedly applied to the skin using a close-fitting water-filled copper thermode, which completely enclosed the rat's tail; the temperature of the water flowing through the thermode could be rapidly changed from 31° C. to 46° C. to 4° C. During each period of cooling there was a constant rate of fall of skin temperature from 31° C. to 4° C., and during each period of heating there was a constant rate of change of temperature from 31° C. to 46° C., the period of time for which the skin was heated at 46° C. or cooled at 4° C. was 10 min., and between periods of thermal stimulation the skin temperature was returned to 31° C. for 10 min. The pattern of firing recorded in the single fibre preparations during cooling was of two types, first those fibres which fired phasically, only during the fall of skin temperature, and secondly those fibres which fired continuously throughout the 10-min. period of cooling at 4° C. In the latter case the highest frequencies of firing (max. 75 imp./sec.) achieved during the fall of skin temperature, and the frequency of firing gradually fall off to a steady level during frequency. The fibres in which a phasic activity was recorded during the fall of skin temperature to 4° C. showed a constant and repeatable activity to consecutive (up to 10) periods of identical cooling. Repeatable activity was also observed in some of the fibres with a continuous discharge at 4° C., others showed evidence of fluctuations of activity.

A continuous, but irregular, discharge of fairly high frequency was observed in all these non-specific *C*-fibres during periods of heating the skin at 46° C. Contrary to the rather repeatable activity recorded from these fibres during successive cooling periods quite large and apparently random fluctuations of response were consistently observed during periods of repeated identical heating. These changes of activity sometimes took the form of potentiation; but diminution of activity or complete changes in the pattern of firing from single impulses to high-frequency bursts of impulses has also been recorded.

It was found that fluctuations of response to identical heating occurred in the same fibres which responded uniformly with phasic responses to cooling the skin at 4° C. There was also some evidence that similar fluctuations, though less marked, might also occur during repeated periods of identical cooling at 4° C. in some of the fibres that fired continuously while the skin was at 4° C. The fluctuations of response to repeated cooling at 4° C. was more marked if the skin had been previously subjected to repeated periods of heating at 46° C.

The nature of these changes of response is unknown, but we can consider two possible mechanisms that could account for this effect:

(1) It might be similar to the potentiation or depression taking place after previous activity in the Pacinian corpuscles described by Loewenstein and Cohen[5,6]. These changes increase with increasing previous activity of the corpuscle. In our experiments a change in *C*-fibre activity was only found after stimuli that gave long-lasting firing of rather high frequency.

(2) Due to sustained high temperature of the skin to some degree possibly tissue damage begins. Witt[3] has shown that, after repetition of noxious stimuli

which do not cause irreversible destruction of skin receptors, the sensitivity of non-specific *C*-fibres increases in response to all kinds of stimuli. Chemical reactions, that is, local production of special substances, may be responsible for this effect.

Because of the non-specificity and the fluctuation in activity of the fibres observed in our experiments, we suggest that they might have a nociceptive function rather than a function as thermoreceptors. The sensation of pain may therefore be mediated by the stimulation of these non-specific afferents, rather than by excessive stimulation of specialized thermoreceptors or mechano-receptors.

Potentiation by Anæsthetics of Brain Damage due to breathing High-Pressure Oxygen in Mammals

THERE have been several reports that barbiturates administered to animals before their exposure to high-pressure oxygen reduce the incidence and severity of convulsions and delay death[1-4]. We have confirmed this protective action for barbiturates in mice and rats and have also shown that lung damage in rats due to exposure to high-pressure oxygen is decreased[5]. However, when rats were exposed for shorter periods to high-pressure oxygen, which did not result in acute death during pressurization, and were allowed to recover, it was found that pretreatment with anæsthetic doses of pentobarbital sodium (37·5 mgm./kgm. body-weight, intraperitoneally) immediately before exposure to high-pressure oxygen resulted in a very marked increase in delayed damage to the central nervous system.

In Table 1 representative results are shown for male rats, weighing 160 gm., exposed to 45-lb./sq. in. gauge pressure of pure oxygen for varying periods. All rats were compressed after flushing of the pressure vessel at a rate of 15 lb./sq. in./min. and decompressed at 9 lb./sq. in./min. The treatment periods refer to the actual times during which 45-lb./sq. in. gauge pressure was maintained in the chamber. The incidence and times of convulsions and death were recorded, and 24 hr. after pressurization the incidence and severity of damage to the central nervous system were assessed.

Among unanæsthetized animals no deaths or obvious residual brain damage resulted from exposure to oxygen at 45 lb./sq. in., for as long as 45 min. In rats previously given pentobarbital sodium, the incidence of deaths was increased, and animals showed residual brain damage following exposures of only 15 min. to oxygen at a pressure of 45 lb./sq. in. The delayed lesions to the central nervous system that we observed follow closely the pattern described by Bean and Siegfried[6], although their classification of acute and chronic phases was less apparent. Some affected animals showed either hyperexcitability or lethargy (classified as mild damage) and a number showed unsteadiness of gait and postural disturbances (moderate damage). However, most of the affected rats featured gross motor dysfunction (severe damage), particularly flexor paralysis of the fore limbs resulting in a kangaroo-like locomotion. A more extensive paresis was also common and resulted in spastic deformities with opisthotonus. Some rats showed catatonic behaviour while others were comatose. In the latter, hypothermia was usually severe and commonly preceded delayed death.

Table 1. EFFECT OF BARBITURATE ANÆSTHESIA ON LETHALITY AND BRAIN DAMAGE IN RATS EXPOSED TO PURE OXYGEN AT 45 LB./SQ. IN. GAUGE PRESSURE

	Treatment	Fraction of animals dead within 24 hr. after exposure	Fraction of animals showing residual brain damage 24 hr. after exposure
Exposure for 15 min.	Unanæsthetized	0/3	0/3
	Pentobarbital Na (37·5 mgm./kgm.)	0/3	2/3
Exposure for 25 min.	Unanæsthetized	0/12	0/12
	Pentobarbital Na (37·5 mgm./kgm.)	3/9	6/6
	ββmethylethyl glutaramide (40 mgm/kgm.) and pentobarbital Na (37·5 mgm./kgm.) both before exposure	0/3	0/3
	Pentobarbital Na (37·5 mgm./kgm.) before exposure, ββ-methylethyl glutaramide (40 mgm./kgm.) after decompression	0/3	3/3
	ββmethylethyl glutaramide before exposure	3/3*	—
Exposure for 45 min.	Unanæsthetized	0/6	0/6
	Pentobarbital Na (37·5 mgm./kgm.)	0/6	6/6
	Pentobarbital Na (37·5 mgm./kgm.) before exposure, ββ-methylethyl glutaramide (40 mgm./kgm.) after decompression	1/3	3/3
Exposure for 60 min.	Unanæsthetized	3/3*	—
	Pentobarbital Na (37·5 mgm./kgm.)	1/3*	2/2

* Deaths in chamber occurred during exposure to high-pressure oxygen.

It was also found that a barbiturate antagonist, ββmethylethyl glutaramide (megimide), in large doses protected against this potentiation of damage to the central nervous system by barbiturates, only if given with the barbiturate before pressurization of the rats. We have since found that anæsthetic doses of paraldehyde results in a similar potentiation of the central nervous system after effects of oxygen poisoning. Barbiturate anæsthesia also potentiated delayed damage to the central nervous system in mice exposed to high-pressure oxygen. However, large doses of chlorpromazine or reserpine, sufficient to cause severe hypothermia, failed to increase damage to the central nervous system after exposure to high-pressure oxygen.

This paradoxical action of anæsthesia in accentuating delayed damage to the central nervous system due to oxygen poisoning, while protecting against acute damage, has important practical implications and is at present the subject of further investigations in this laboratory. It would seem that chemical protection against the acute effects of high-pressure oxygen poisoning is largely due to a lowering of metabolic rate[7,8] or possibly a reversal in tissue redox potential changes which may result from exposure to high-pressure oxygen. However, organic nervous system damage due to exposure to high-pressure oxygen appears refractory in this regard and possibly is related to raised cerebral carbon dioxide tension and its effect on cerebral vascular calibre and cerebral oxygen tension[9]. Preliminary investigations have shown that if respired carbon dioxide tensions are maintained at higher levels during exposure to high-pressure oxygen, delayed effects in the central nervous system are increased in unanæsthetized rats.

Effect of Mucopolysaccharides and Colloid on the Function of the Thyroid

In previous experiments we have shown that the serum mucopolysaccharide (hexosamine) content of hyperthyroid patients was considerably less than the normal level. On the other hand, the mucopolysaccharide (hexosamine) content of the blood of hypothyroidic patients was found to be higher than normal and considerably higher than the mucopolysaccharide-level of hyperthyroid patients[1].

It has also been shown that experimental thyroidectomy and methylthiouracyl treatment caused a significant raising of the mucopolysaccharide (hexosamine)-level of the serum of dogs, whereas thyroxine treatment brought about a significant decrease of the serum mucopolysaccharide-level[2]. We have reported too that experiments on rats applying heat and cold stress failed to give tangible results.

In the work reported here carried out on 30 male rats (series 1), we administered thyroxine instead of that of methylthiouracyl over a long period. In contrast to the former experiments in which the changes of the mucopolysaccharide content of the serum were registered within 24 hr., these changes were examined after 25–28 days treatment.

The rats of the control group (10 animals) received a daily injection of physiological saline. The rats of the thyroxine-treated group (10 animals) were given thyroxine (Roche) in increasing daily doses (0·07–0·5 mgm.). The 10 rats of the third group received 75 mgm. methylthiouracyl mixed up in their food daily.

The values of the three groups (average: 90·3, 107·7, 125·7 mgm. per cent) are given in Fig. 1. The average weights of the thyroid glands were: control group, 22 mgm.; thyroxine-treated group, 16 mgm.; methylthiouracyl-treated group, 89 mgm.

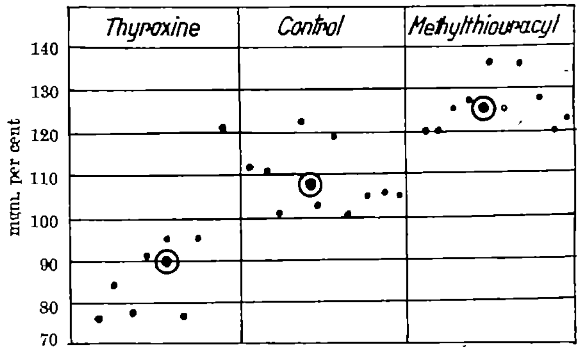

Fig. 1. Serum hexosamine content after 25–28 days treatment

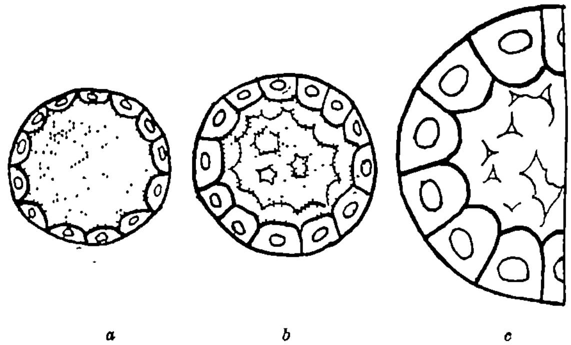

Fig. 2. Thyroid follicle. (*a*) After 27 days of thyroxine treatment flattened cells, accumulated colloid, intense periodic acid – Schiff positivity, hexosamine content, 1,372 mgm. per cent. (*b*) Control: cuboidal cells, normal colloid content; periodic acid – Schiff positivity, hexosamine content, 1,129 mgm. per cent. (*c*) After 27 days of methylthiouracyl treatment. tall columnar cells, scarce remnants of colloid, weak periodic acid – Schiff positivity, hexosamine content, 659 mgm. per cent

In contrast to the histological picture of the normal thyroid, the thyroids of the thyroxine-treated animals showed a flattened epithelium, and large amounts of colloid accumulated in the follicles. On the other hand, animals treated with methylthiouracyl showed a tall columnar lining and only small amounts of colloid. Histochemical investigations (periodic acid – Schiff staining, acetylation, mucase digestion according to Banga and Baló[3], etc.) showed that the colloid of the thyroids of the thyroxine-treated animals contains larger amounts of periodic acid – Schiff positive material than the normal glands, whereas the methylthiouracyl-treated groups show only a very weak positive reaction to periodic acid – Schiff reagent.

Repeating the experiment on 60 female rats (series 2), the average values of serum hexosamine were as follows: 77·1 (thyroxine), 96·4 (control) and 111·7 (methylthiouracyl). In this series we have made parallel biochemical measurements of the hexosamine content of the tissues on the total amount of the glands of the three groups according to Boas's method[4]. The average tissue hexosamine content of 20 normal thyroids was 1,126 mgm. per cent (1,120–1,132); that of 30 thyroxine-treated glands with flattened epithelial cells and much colloid; 1,372 mgm. per cent (1,314–1,430) and the average of 10 methylthiouracyl-treated thyroids with tall columnar cells and only remnants of colloid, 659 mgm. per cent (658–660).

It is thus evident that the hexosamine content is not dependent on the cells but on the colloid (Fig. 2).

These results confirm the assumption based on experiences with man and dogs that thyroid function has an important role in the regulation of the mucopolysaccharide (hexosamine)-level of the serum. In addition to this regulating role of the thyroid, the experiments seem to demonstrate the histological, histochemical, enzymological and biochemical correlation existing between the colloid and hexosamine content.

Effect of Additions of Sodium and Potassium and of Peritoneal Dialysis with a Hypotonic Solution of Sodium Chloride on the Sodium and Potassium Contents of the Maternal and Fœtal Serum and the Amniotic Fluid of Rats

Electrolytic changes undergone by the mother will lead, both in man and animals, to similar changes in the fœtus within a few hours[1,2]. We have been able to establish that when gravid rats and guinea pigs are subjected to a 2–3-day period of thirsting there is serious damage of the fœtus at the end of pregnancy—a large number of stillbirths or of non-viable young[3]. In order to study the effects of short-term additions, Wistar rats, weighing about 200 gm., were given, on the nineteenth day of pregnancy, 1·7 m.equiv./100 gm. body-weight of sodium in a 20 per cent sodium chloride solution, or 0·8–1·5 m.equiv./100 gm. body-weight of sodium was removed by peritoneal dialysis with 0·5 per cent sodium chloride solution. Another series of animals was given 1·5 m.equiv. potassium in isotonic solution of potassium chloride, intraperitoneally. As there was rapid renal elimination of potassium, 1·0 m.equiv. potassium was administered intraperitoneally to a further series of animals after bilateral nephrectomy. At fixed periods samples of blood from the vena cava inf., of amniotic fluid and of fœtal blood from the umbilical vessels were taken from the animals, which had been anæsthetized with ether, and the sodium and potassium in the serum and amniotic fluid were determined by photometric flashes. We used lithium as a standard and utilized the emission-increasing effect of methanol[4] when determining the potassium content. The animals were given neither food nor drink during this time.

Fig. 1 (upper part) shows the changes observed after addition of sodium and (lower part) after dialysis with a hypotonic solution of sodium chloride, as against 10 control animals (maternal serum: 136 ± 3·6 m.equiv./l., fœtal serum: 146 ± 7·9 m.equiv./l., amniotic fluid: 136 ± 4·3 m.equiv./l.). Figs. 2 and 3 show the changes, after the addition of potassium, in potassium content of the three above-mentioned fluids. The control values for Fig. 2 are:

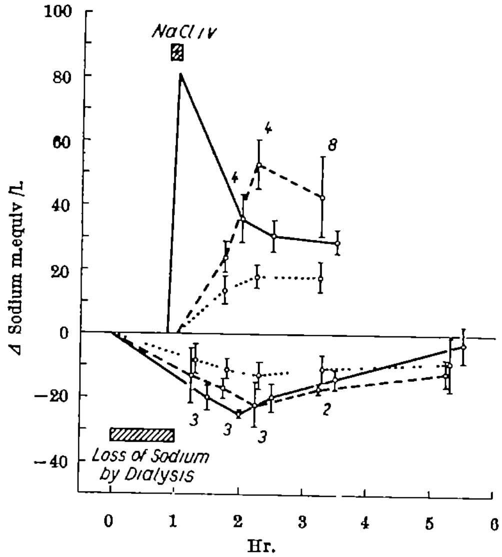

Fig. 1. Differences in the sodium concentration with standard deviations from the control values (= 0) after administration of hypotonic solution of sodium chloride (upper part of diagram) and (lower part) peritoneal dialysis with hypotonic solution. ——, Maternal serum; – – –, fœtal serum; · · · ·, amniotic fluid

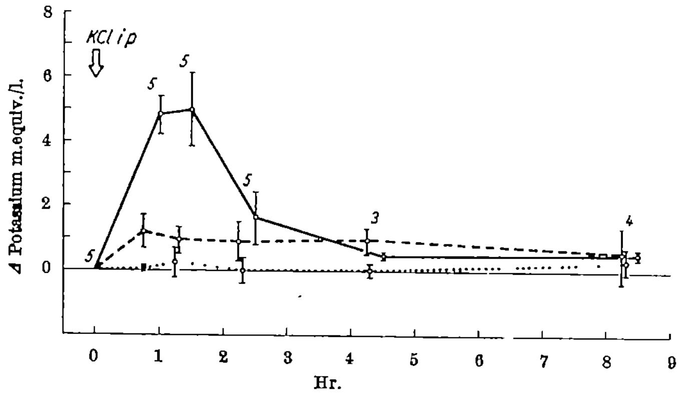

Fig. 2. Differences in the potassium concentration as against the control values (= 0) after intraperitoneal injection of isotonic solution of potassium chloride. ——, Maternal serum; – – –, fœtal serum; · · · ·, amniotic fluid

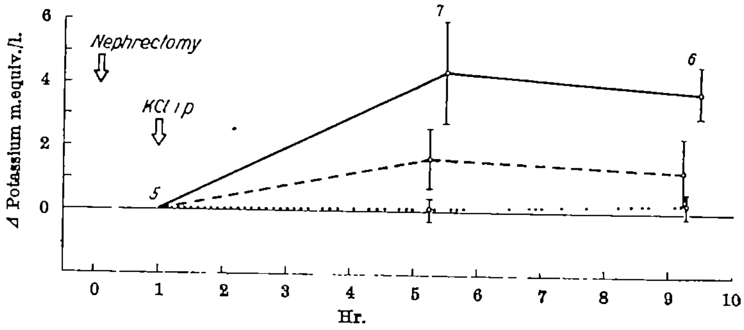

Fig. 3. Differences in the potassium concentration as against the control values (= 0) after intraperitoneal injection of isotonic solution of potassium chloride with bilateral nephrectomy. ——, Maternal serum, – – –, fœtal serum; · · · ·, amniotic fluid

maternal serum, 3·55 ± 0·35 m.equiv./l.; fœtal serum, 4·98 ± 0·38 m.equiv./l.; and amniotic fluid, 4·79 ± 0·30 m.equiv./l. For Fig. 3: maternal serum, 4·26 ± 0·33 m.equiv./l.; fœtal serum, 5·90 ± 0·63 m.equiv./l.; and amniotic fluid, 5·42 ± 0·40 m.equiv./l.

All tests showed abnormal behaviour (apathy and cramp) of the mother animals, and in the case of the fœtus noticeably slight mobility, when the osmotic balance was disrupted.

The tests show that changes in the mother animal lead to protracted, usually lesser but more lasting, changes in the fœtus, but to much slighter changes in the fœtal water. The high sodium values where sodium had been given, and the low ones for the case of dialysis, may be attributed primarily to a disruption of the water supply. Work by Flexner[5-7] indicates that there is a much greater exchange of water than of sodium between the maternal and fœtal fluid-spaces. Similarly, the inconsiderable changes in the fœtal water accord well with investigations by Flexner[8]. Potassium is eliminated so rapidly through the maternal kidneys that the potassium content of the fœtal serum increases only slightly. In the case of animals with nephrectomy a gradual increase is more in evidence. Unless the high potassium-level in the case of the animals without nephrectomy is, likewise, to be attributed to a loss of fœtal water, potassium is retained by the fœtus. This conclusion would agree with recently published results by Stewart and Welt[9], who found that a diet deficient in potassium and dialysis with solution of sodium bicarbonate resulted in a much more considerable loss of potassium in the maternal than in the fœtal tissues.

PHARMACOLOGY

An Antigen in Malignant and in Embryonic Tissues

A NUMBER of human tumours have been found to grow in cortisone or hydrocortisone-treated weanling rats and in hamsters. Growth cannot be obtained without the use of cortisone or adrenocorticotrophic hormone. It is well known that these animals develop an immunity against the implanted tumour.

We have been interested in trying to determine the basis of this antigenic activity and, to this end, have injected human sera or homogenates of various human tumours or other human tissues into weanling rats. Seven days later these animals were challenged with the transplantable human tumour *HS*1, and at the same time, and again later, injected with cortisone.

The antigenic response was assessed by comparing the growth of this tumour *HS*1 in control rats and in the rats thus 'immunized'.

Potent antigenic activity, producing almost complete growth inhibition, has been found in homogenates of tumour *HS*1, and of rapidly growing sarcomata recently removed from patients as well as in a variety of fœtal tissues, for example, spleen, and to a lesser extent skeletal muscle. On the other hand normal human plasma or serum is practically inactive and a homogenate of normal human adult muscle has little effect. So far as can be determined this effect is not related to the blood group or the *Rh* factors.

Table 1. INHIBITION OF GROWTH OF SARCOMA *HS*1 IN RATS PREVIOUSLY TREATED WITH NORMAL AND MALIGNANT HUMAN TISSUE

No. of samples tested, each on a group of 6 'immunized' rats	Tissue injected as antigen	Tumour size in arbitrary units after 14 days growth		Per cent of inhibition of tumour growth
		Control rats	'Immunized'* rats	
	(*A*) *Normal tissue*			
29	Adult serum	1·34±0·10	1·5±0·14	None
12	Adult muscle	1·8±0·28	1·87±0·40	24
9	Fœtal muscle	1·77±0·20	0·38±0·10	79
4	Fœtal spleen	1·77±0·13	0·07±0·05	96
	(*B*) *Malignant tissue*			
190	*HS*1	2·0±0·17	0·15±0·17	92
2	Melanotic sarcomata *M* and *G*	2·2	0·1	96
1	Chondroma *R*	2·3	0·05	98
1	Synovial sarcoma *J*	2·0	0·1	95

* Immunized rats are injected with antigen 7 days before challenge with tumour and cortisone treatment.

The antigen appears to be very labile in that it is destroyed by freezing and thawing and disappears on prolonged storage. M. J. How has found that it may be included in the methanol-chloroform fraction of the tumour extract.

Embryonic tissue is very active as an antigen and thus resembles malignant tissue: it appears possible that antigenic activity is related to the high rate of cellular division in these tissues which may accentuate the potency of an antigen present in normal human tissues.

The high incidence of carcinoma of the lung in Cushing's disease patients with their increased hydrocortisone blood-level is possibly a pointer to the importance of cortisone in allowing the implantation and growth of cancer cells in man.

Rapid Hepatic Shift of Worms in Mice infected with *Schistosoma mansoni* after a Single Injection of Tartar Emetic

MUCH work has already been carried out on the treatment of mice infected with schistosomes. It has been observed that the worms which normally inhabit the mesenteric veins of animals infected with *Schistosoma mansoni* are forced to migrate to the liver after treatment with active schistosomicidal drugs[1-6]. This hepatic shift has usually been observed after a full course of treatment, and where the course had been inadequate, relapses were found to occur owing to the re-migration of the worms back to the mesenteric veins. Standen[6] observed a hepatic shift as early as one day following two oral doses of 42 mgm./kgm. sodium antimonyl III gluconate, but after 7 days the worms were completely restored to their normal distribution in the hepatic portal system. In the work reported here we followed up the effect of a single dose of tartar emetic on the worm migration to show that the hepatic shift actually occurs much earlier than had been previously expected.

Five groups of mice infected with *Schistosoma mansoni* were used 9 weeks after infection. Each group consisted of 10 mice: one group was used for controls and each of the remaining four groups were given an intraperitoneal injection of tartar emetic 25 mgm./kgm. and autopsied at intervals of 30 min., 2 hr., 8 hr. and 32 hr. respectively. After ligaturing the portal vein immediately after death, the number of worms in the mesenteric veins, portal vein and liver were counted separately. In the latter procedure, the liver-crush technique described by Standen[6] was used.

Table 1. DISTRIBUTION OF SCHISTOSOMES IN THE HEPATIC-PORTAL SYSTEM OF THE MOUSE FOLLOWING AN INTRAPERITONEAL INJECTION OF TARTAR EMETIC

Group (10 mice per group)	Post-treatment period (hr.)	Average No. of worms/ mouse	Distribution of worms (per cent)		
			M	*PV*	*L*
1	½	13	10	12	78
2	2	13	2	2	96
3	8	12	0	10	90
4	32	15	35	31	34
Controls	—	13	75	21	4

M, mesenteric veins, *PV*, portal vein; *L*, liver.

The results are summarized in Table 1, which shows the percentage of worms in the mesentery, in the portal vein and in the liver at the various time intervals investigated.

It is evident that the worms start migrating from the mesentery to the liver in even less than half an hour after the injection of tartar emetic, and that by the end of 2 hr. this hepatic shift is virtually complete and practically all the worms are then located in the liver. At 8 hr. after injection the worms are gradually making their way back to the mesentery, and by 32 hr. only one-third of them are still left in the liver.

This rapid hepatic shift may conveniently be explained on the ground that the schistosomes lose their muscle tone as soon as the drug reaches them in an effective concentration. They thus lose their grip on the mesenteric blood vessels and are then swept back to the liver by the blood stream within 2 hr. of the drug treatment. The schistosomes start migrating back, however, as soon as the effective concentration of the drug in the blood drops and they begin regaining their muscular activity. The process of re-migration back to the mesentery undoubtedly takes much more time than the actual hepatic shift since the worms have now to travel against the direction of the blood flow.

The hepatic shift thus occurs very soon after the drug is given and is much quicker than had been previously reported by earlier workers. This rapid effect, together with the slow return of the worms to the mesentery, may have an important bearing on the optimum time interval between doses of antimonials and possibly of other drugs administered in the course of treatment of human schistosomiasis.

RADIOBIOLOGY

Whole-Body Oxygen Consumption during Irradiation for the Survival of Rats after Exposure to X-rays

THE study of consumption of oxygen by animals during irradiation enables one to follow the influence of the intensity of metabolic processes in the organism from the start of the action of ionizing radiation and, consequently, contributes to elucidating the frequent changes in the metabolic processes of the organism evoked by radiation. In previous papers[1,2] we demonstrated the raised consumption of oxygen in rats, rabbits and chickens during their exposure to X-rays. In the present experiment I examined the relation between whole-body oxygen consumption during irradiation (cm.^{3} 100 gm. min.$^{-1}$) and the survival of animals irradiated with 600 r. and 700 r. of X-rays. (The X-ray controlling factors were 180 kV., 15 m.amp., filter 1 mm. aluminium., 0·5 mm. copper, focal distance, 50 cm., dose-rate 50 r./min.)

180 male Wistar rats were used, having an average weight of 190 gm. The rats were divided into two groups, the first consisting of 80 rats irradiated with 600 r. of X-rays, and the second 100 rats irradiated with 700 r. X-rays.

Each animal was placed in a 'Umaplex' chamber and its oxygen consumption measured. The amount of air passing through the chamber depended on the weight of the animal. Measurements were taken and irradiation commenced from the second minute after placing the rat in the chamber. The technique of measurement has been described elsewhere[3].

Fig. 1 shows the oxygen consumption during exposure of rats irradiated with 600 r. of X-rays (equivalent to $LD_{50/30}$) and its relation to their survival. The correlation of oxygen consumption during exposure and the survival of irradiated animals reveals a statistically significant relationship ($r = 0 \cdot 72$, $n = 80$, $P < 0 \cdot 01$), according to which rats with a higher absolute oxygen consumption survive 30 days post irradiation, while animals the oxygen consumption of which during exposure to X-rays is rather low usually perish within the first 10 days after irradiation.

After a dose of 700 r. (equivalent to $LD_{100/12}$) the survival-time of the animals shows a positive correlation with their oxygen consumption during irradiation (Fig. 2). According to this, animals with a lower oxygen consumption perished much sooner. In this part of my experiment the correlation is statistically significant when adding up the absolute consumption of oxygen prior to and during irradiation ($r = 0 \cdot 66$, $n = 100$, $P < 0 \cdot 01$).

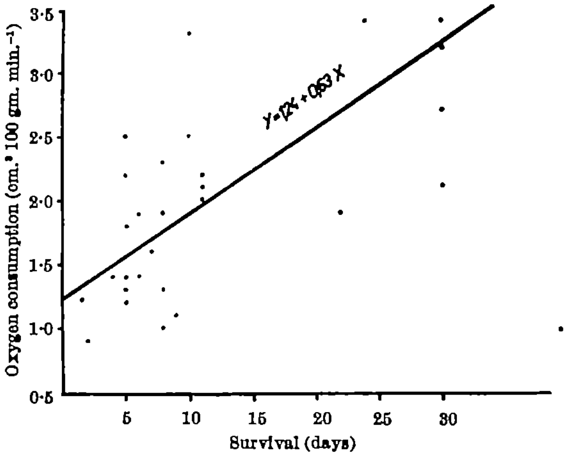

Fig. 1. Relation of oxygen consumption to survival after exposure to 600 r.

The results of these experiments follow my previous work concerning oxygen consumption of animals during irradiation[3,4], in which I demonstrated that raised oxygen consumption of rats during irradiation is dependent on the peripheral nerve tracts passing through the spinal cord being intact[5].

It is obvious that a rise in the oxygen consumption during exposure to X-rays is an indication of the reactivity of the irradiated animal. Since the oxygen consumption of rats immediately after being placed in the chamber is not effected in the same way for all animals[6], the absolute values for oxygen consumption obtained are, under given conditions, determined to a considerable extent by the way in which the individual animals react to the X-rays.

Consequently, it would seem that the relation between oxygen consumption by rats during exposure to X-rays and their survival is dependent above all on the state of reactivity of the animals during irradiation.

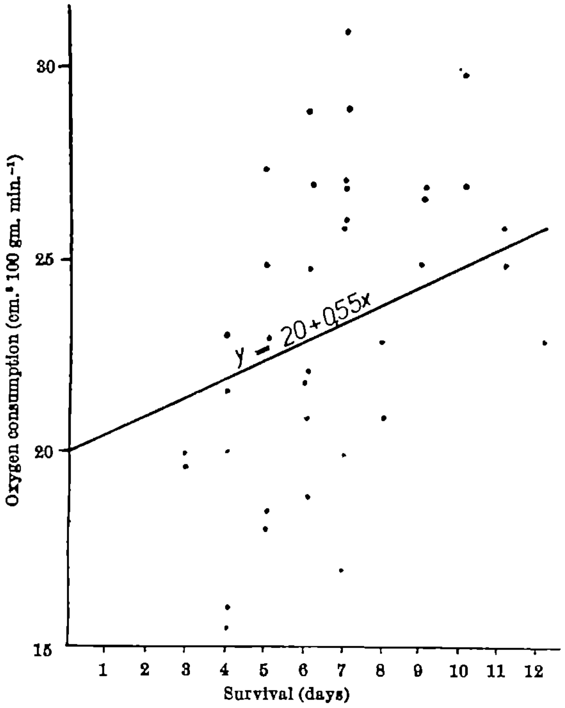

Fig. 2. Oxygen consumption during exposure to 700 r. and its relation to survival

Radiation Protection with Sulphur and Some Sulphur-containing Compounds

It is known that many biological systems can be protected in part against the effect of ionizing radiation by the presence of very small amounts of additives. It is often difficult to assess the mechanism of this protection due to the complex nature of the system. The effect of radiation on simple organic polymers can also be reduced by various additives. It is believed that this offers many analogies with protection in the more complex biological systems.

The present investigations involve the use of both non-aqueous and aqueous polymer systems; the former being by polydimethyl siloxane fluids and the latter dilute aqueous solutions of polyvinylpyrrolidone. We examined the effect of a wide variety of additives on the behaviour in these systems when exposed to γ-radiation.

The purpose of this communication is to report the high efficiency shown by colloidal sulphur suspensions in very low concentrations (in the range of 5–50 μgm./c.c.) in inhibiting the cross-linking of the investigated systems. This was readily shown by an increase (by a factor of 2 or 3) in the dose to bring about gelation. For the aqueous solutions, for example, this dose was increased from 2 to 6 megarads. This degree of protection is even more remarkable when it is remembered that the sulphur was present in the form of relatively large colloidal particles and not as molecules dispersed at random. A high efficiency in protection by sulphur in aqueous protein solutions was previously reported[1,2].

A similar effect of protection was shown by many sulphur-containing compounds which were used in the dilute aqueous polyvinylpyrrolidone solutions. It is not yet established whether the protection by these compounds is offered by an initial release of sulphur or by an alternative route.

The ability of sulphur to protect macromolecules against cross-linking under irradiation was found to be too large to agree with previously proposed mechanisms involving radical scavenging. This mechanism is, however, present with certain other additives. Further details of this work will be published shortly.

Experimental Oxidation of Hæmoglobin Effects of Irradiation in Rats

The sensitivity of human intracellular hæmoglobin to oxidation by nitrite ions is raised during growth, pregnancy in malignant disease and in some other conditions[1]. It has also been shown to be increased in similar circumstances in the rat[2,3] and in this animal the changes appear to be related to riboflavin metabolism[2–4]. Both riboflavin deficiency[5] and X-rays interfere with growth and are teratogenic. The effect of radiation on the stability of hæmoglobin against oxidation by nitrites has now been studied in the rat. A dose of 500 r. was chosen ($< \mathrm{MLD}_{50}$) and was administered at approximately 20 r./min.

The age of the rat at irradiation had a definite effect on the reaction of the animal to this dose (cf. ref. 6). The growth-rate of suckling rats was only slightly affected, weaned but immature rats suffered a temporary pause of about one week in their growth, while mature rats lost weight for the week following irradiation.

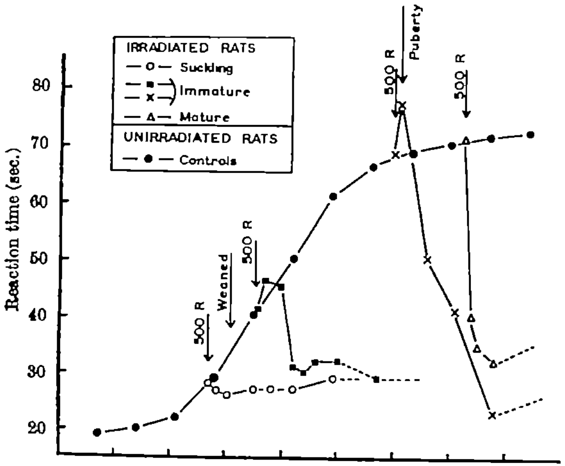

Fig. 1. Change in the reaction time (the time taken to convert the hæmoglobin of a standard saline red cell suspension to methæmoglobin using 0·1 per cent sodium nitrite (*in vitro*) with age and the effects of 500 r. cobalt radiation at various ages. (The *S.D.* of any point is approximately ± 5 sec.)

While the ultimate effect on the hæmoglobin oxidation sensitivity—marked increase in the hæmoglobin oxidation sensitivity for at least three months—is identical whatever the age at irradiation, the initial changes did vary with age (Fig. 1). Suckling rats merely retain the increased sensitivity of the rapidly growing animal into adult life. Mature rats, from puberty to old age, respond to irradiation with an immediate increase in their hæmoglobin oxidation sensitivity to levels found normally in the young or pregnant. Weaned, but still immature, rats, however, exhibit the ultimate increased sensitivity of their hæmoglobin only after an initial period of 3–4 days decreased sensitivity.

The increased hæmoglobin oxidation sensitivity of starving, young or pregnant rats can be altered towards the normal by 2 mgm. of riboflavin given subcutaneously[3,4]. That riboflavin or flavin mononucleotide is without effect in the increased sensitivity following radiation but is effective when given in conjunction with adenosine triphosphate (Table 1) supports the suggestion[7] that some at least of the effects of radiation are due to interference with oxidative phosphorylation.

Table 1. The Effect, in Irradiated Adult Rats, of the Injection of Various Substances on the Time (Sec.) taken to oxidize their Intracellular Hæmoglobin to Methæmoglobin by a 0·1 per cent Solution of Sodium Nitrite *in vitro*. (*S.D.* given, samples of five animals.)

Substance injected	Reaction-time at intervals after injection			
	Before	1 hr. after	2 hr. after	4 hr. after

Dose Effect Curve of Somatic Mutations in *Ephestia kühniella* Z. for Low Dose-range (0–200 r.).

Ephestia kühniella Z., the meal moth, proved to be a good object for investigation of quantitative relations between somatic mutations and ionizing radiations[1,2]. These former investigations were concerned with relative high doses (100–1,000 r.). It seemed interesting to extend the experiments to the lower dose-range, since there is a complete lack of knowledge of this part of the dose effect curves of somatic mutations in animals.

On each of the hind-wings of *Ephestia* there are about 6,250 scales of uniform shape and colour. After irradiation at an early stage of development clusters of scales of different appearance are found, which have been described as somatic mutations[3]. After irradiation of 10–16 hr. old pupæ these mutations only affect single scales, so that the mutation-rate can be measured directly from the proportion of mutated scales to the total number of scales. This calculation is valid only on the assumption that the irradiation has no lethal effect on the mother-cells of the scales, no matter how high the dose. In order to ascertain this fact the number of scales on 6 wings of individuals irradiated with 10 resp. 200 r. was determined and the mean values proved to be not significantly different (6,270/wing and 6,233/wing, $P = 0{\cdot}8$).

Groups of at least 40 pupæ were exposed to one of the different doses (10, 20, 40, 80, 200 r., and control), and both wings of 30 randomly chosen individuals were examined for mutations. This experiment was repeated twice, so that for each dose 3 × 30 × 2 × 6,250 = 1,125,000 scales were classified. For the irradiations an *RT* 100 X-ray apparatus (C.H.F., Hamburg) was used, running at 100 kV., with a 1·7 aluminium filter and a dose-rate of 133 r./min.

Table 1. *ES* 1 Mutation Rates for Controls and for Different X-ray Dosages

Dose (r.)	Exp. I	Exp. II	Exp. III	Total
0	9	4	6	19
10	7	8	7	22
20	15	14	10	39
40	17	12	15	44
80	31	25	19	75
200	69	66	67	202
Total	148	129	124	401

Several mutant types are found in *Ephestia* scales, but here only the results of the most frequent type (*ES* 1) are reported. Table 1 shows the number of mutations obtained in the three experiments. The differences between experiments all lie within the range of chance deviations. Fig. 1 presents the sum total of mutations for each dose with the confidence limits for a $P = 0{\cdot}05$, calculated according to the method proposed by Stevens[4]. It is possible to fit a linear regression line to these data (line *a*). A χ^2 test based on the differences between the observed values and the values expected from a linear regression results in a $P = 0{\cdot}5$–$0{\cdot}3$, which shows that the experimental data are consistent with the hypothesis of an increase of mutation frequencies proportional to the dosage of 0–200 r., with no indication of a threshold.

However, earlier experiments with higher doses (100–1,000 r.) resulted in a dose-effect curve, which was decidedly non-linear but was proportional to the square of the dosage ($P = 0{\cdot}5$–$0{\cdot}3$) (Fig. 2). It is therefore to be expected that in the lower dose-range the curve follows the same rule. A χ^2 test for a straight regression line after a quadratic transformation of the abscissa, however, results in a $P = 0{\cdot}05$–$0{\cdot}02$. The main contribution to the high χ^2 value comes from the control- and 10 r.-points. A χ^2 test, which omits these two values, so that only the doses 20, 40, 80, and 200 r. are included in the calculation, yields a $P = 0{\cdot}9$–$0{\cdot}8$, which signifies a very close fit to the expectation (Fig. 1, line *b*). A linear regression for the same dose-range has a *P* of only 0·3–0·2. The same trend shows up not only in the sum total of the data but also in each experiment separately. These results therefore justify the conclusion that in the range of 20–1,000 r. the increase in mutation frequency is proportional to the square of the dose, whereas for 0 and 10 r. this relation no longer holds good. Both values are significantly smaller than expected. If very low doses have any effect at all, then it must be much smaller than would be expected from the results of irradiations with higher doses.

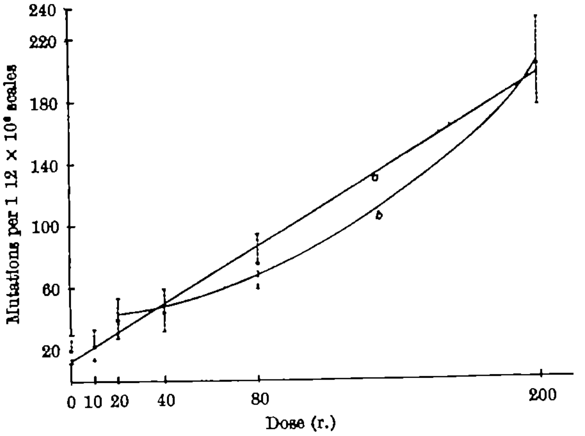

Fig. 1. *ES* 1 mutation-frequencies at X-ray doses of 0–200 r., with 5 per cent fiducial limits. *a*, Regression line proportional to dose; *b*, regression line proportional to dose²

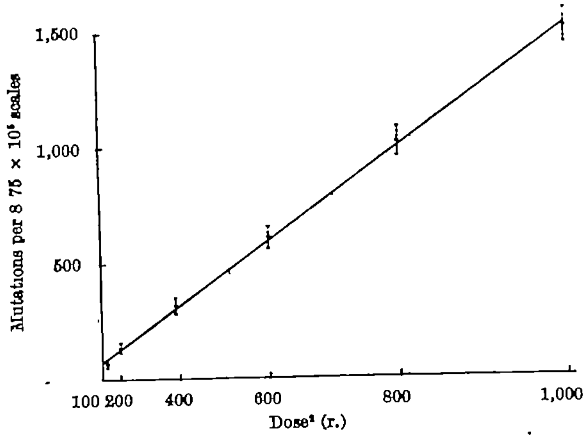

Fig. 2. *ES* 1 mutation-frequencies at X-ray doses of 100–1,000 r., with 5 per cent fiducial limits and a calculated regression line proportional to dose²

BIOLOGY

Dry-Mass Distribution of Bone Marrow Free Cell Population in the Mouse as determined by Interference Microscopy

The hæmopoietic function of the bone marrow is of primary importance in the defence and normal maintenance of the body. Rapid formation of the cellular dry mass in the precursor cells of the bone marrow is essential to produce more blood cells to replenish the diminishing reserve pools in times of stress or emergency. The determination of a distribution curve for bone marrow cellular dry mass in the normal marrow cell population is essential, for this curve can serve as a base-line for the investigation of changes in dry mass distribution of bone marrow after irradiation, drug treatment, toxicity, trauma or disease, or as an assessment of the extent of damage and/or of recovery following insult to the body.

The femoral bone marrow of healthy LAF_1 black male mice from the Jackson Memorial Laboratories. Bar Harbor, approximately 3 months of age and 22–25 gm. body-weight, were used as a source of material for this work. Live cell slides from the marrow were obtained by killing the animals by a quick blow on the head. The two femurs were immediately severed from the body and the two ends of the femur were cut off with a sharp knife. Only a short middle section was retained for its marrow. The marrow was washed out from the section with a drop or two of phosphate buffered (*p*H 7) isotonic saline by inserting a No. 25 needle on a 2-ml. syringe

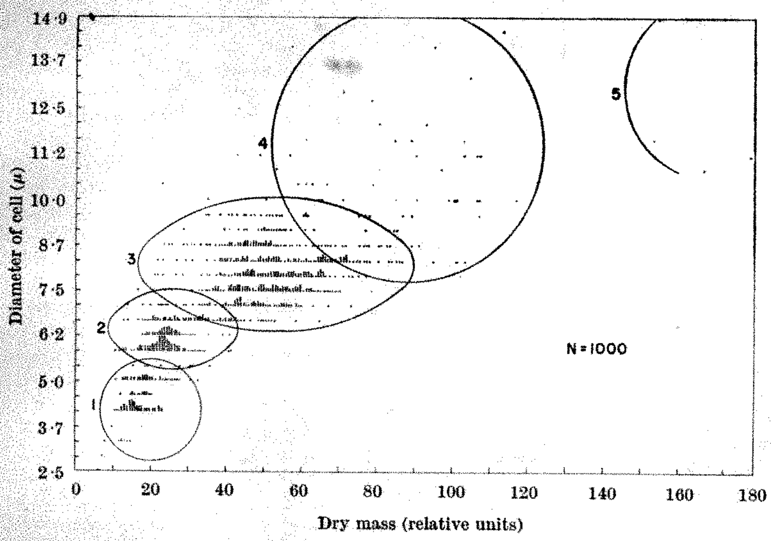

Fig. 1. Size and dry-mass dispersion of the *LAF*$_1$ mouse femoral bone marrow cells. The cells can be divided into five groups (circled areas) according to their diameter and dry mass

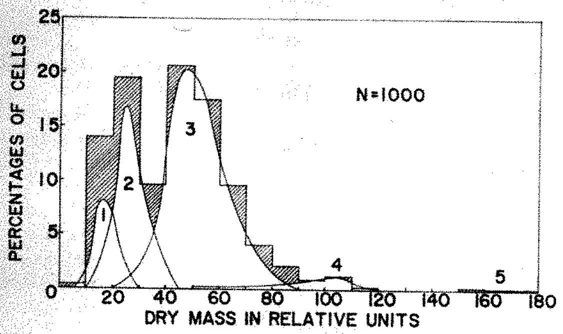

Fig. 2. Dry-mass distribution of the *LAF*$_1$ mouse femoral bone marrow cells. The cells were divided into five dry-mass groups according to the data obtained from Fig. 1. A curve for each group was approximated and fitted into the histogram to show the approximate dry-mass distribution of each group

into the bone marrow cavity. The saline with the washed-out marrow was carefully deposited on a clean slide. The cells were dispersed evenly in the saline by shaking the slide a few times in a rotary motion. A cover-glass was then placed over the cell suspension and gently pressed down to flatten the cells slightly without injuring them. The excessive fluid around the cover-glass was blotted off and the cover-glass was sealed on the slide with paraffin. The slide was immediately put under the interference microscope for dry mass determination. Twenty-five single cells chosen at random were measured from each femur, making a total of 50 cells from each animal. In all, a total of 1,000 cells were measured from 20 animals. The megakaryocytes were excluded from these measurements. They were mostly crushed when the cover-glass was pressed down to flatten the other cells, an essential for accurate measurement. The dry mass of the cells was calculated according to the method published previously[1].

An A—O interference microscope with a × 100 water immersion shearing objective and condenser, and an attached half-shade eyepiece were used for the determination of dry mass. The mercury green line ($\lambda = 0{\cdot}546\mu$) isolated from a mercury lamp served as the light source.

Table 1

Group No.	Diameter (μ)	Dry mass in relative units
1	2·5– 5	10– 30
2	5·4– 7·1	10– 45
3	6·6–10	20– 90
4	8·3–14·5	50–120
5	11·2–	150–

A scatter diagram (Fig. 1) was made to show the dispersion pattern of the cells in relation to their dry mass and average diameter as determined by the mean diameter of the long and short axes of the cell. A histogram (Fig. 2) for the dry-mass distribution was also made from the results obtained. The diameter of the cells ranged approximately from 2·5 to 14·5μ and the dry-mass values ranged from less than 10 relative units to 180 relative units. A study of the scatter diagram revealed that the cells could be divided into five different groups according to their size (diameter) and dry weight (dry mass). Table 1 shows the approximate range in size and dry mass values of each group.

Group 1 cells were easily identified as erythrocytes, while cells in the other groups were not differentiable under the interference microscope. Group 5 cells were possibly small megakaryocytes which escaped our screening for their exclusion.

With the above information as a base, individual dry mass distribution curves for each group were approximated and fitted into the histogram (Fig. 2). From the histogram we found that the modes for the dry-mass values were: 10–20 units for group 1, 20–30 units for group 2, 40–50 units for group 3 and 100–110 units for group 4. There were too few cells in group 5 to give valid mode data. These curves as well as the histogram and the scattergram have proved valuable in our preliminary investigations of the changes of dry mass values of mouse bone marrow after X-irradiation. From previous results of changes in cellular mass after drug or serum treatment of Ehrlich mouse ascites cells[1-3], we believe our present studies may be applicable as a means for assessing the toxic side-effect of drugs.

Reciprocal Transplantation of Blastocysts between Rats and Mice

IN an earlier communication[1] it was shown that a mouse blastocyst, transplanted beneath the kidney capsule of a mouse, not necessarily of the same genotype, gave rise to an embryo surrounded by a highly invasive trophoblast. The trophoblast destroyed and infiltrated the host organ.

Table 1. RESULTS OF TRANSPLANTING RAT AND MOUSE BLASTOCYSTS TO THE KIDNEY

	No. of experiments	No. of trophoblasts only	No. of trophoblasts and embryos	Total No. of implants × 100/ No. of experiments (per cent)
Rat→mouse	30	4	0	13
Mouse→rat	43	13	2	28
Mouse→mouse	123	69	27	78
Rat→rat	54	10	0	18

Successful implantation of ova following xenospecific transfer has never been recorded except between goat and sheep[2,3]. This communication deals with the results of transplanting 4½-day-old rat blastocysts beneath the kidney capsule of mice, and 3½-day-old mouse blastocysts to a similar position in rats. Only 1 blastocyst was transplanted to any 1 host organ.

Table 1 shows that the reciprocal transfers were not equally successful. More than a quarter of the mouse blastocysts transferred to the rat 'implanted', and gave rise to a flourishing trophoblast. It invaded and phagocytosed the rat kidney, and exhibited all the characteristics of a mouse trophoblast developing on a homospecific host organ (Fig. 1). In 2 cases the inner cell mass of the blastocyst had differentiated into small and partly necrotic embryos (Fig. 2).

In the rat→mouse transfers the percentage success was much lower. Furthermore, the resultant trophoblast was stunted and poorly developed. No proliferation of the inner cell mass occurred. A comparable difference in the viability of ova following transfers between rat and mouse has been observed by Briones and Beatty[4]. In their experiments, 8-celled mouse ova transferred to the rat uterus underwent one further cleavage division; but in reciprocal transfers rat ova failed to undergo any further development.

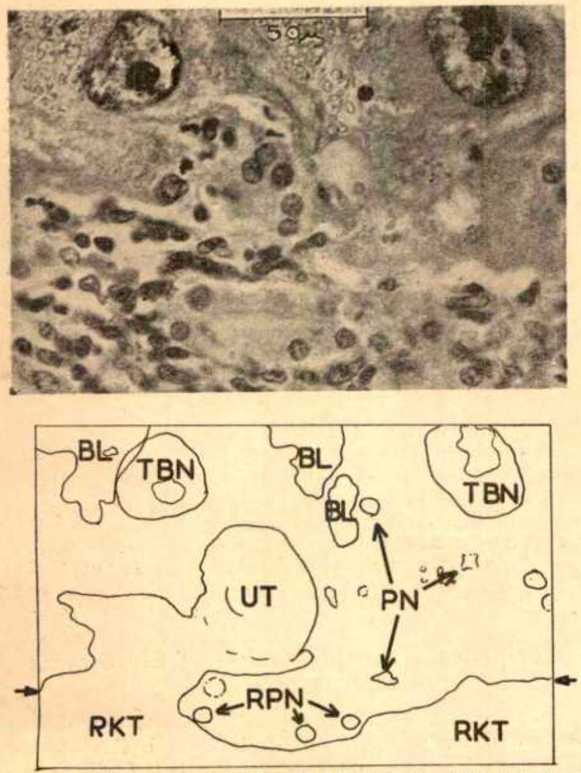

Fig. 1. Mouse trophoblast invading rat kidney. *TBN*, Nucleus of trophoblast cell; *BL*, lacuna of extravasated host blood; *PN*, phagocytosed nuclei; *RPN*, recently phagocytosed nuclei; *UT*, uriniferous tubule; *RKT*, rat kidney tissue. Marginal arrows indicate the limit of the trophoblast

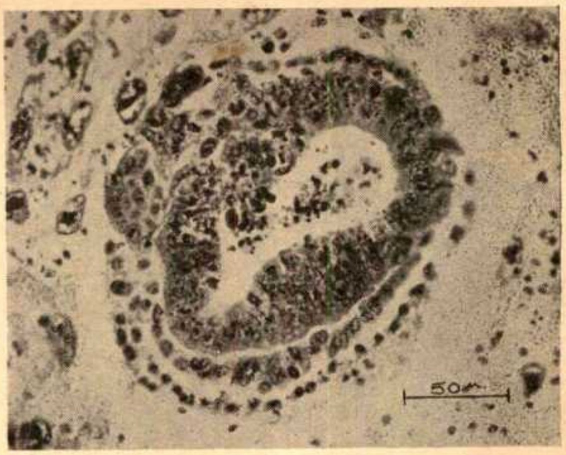

Fig. 2. Section of a mouse embryo developing on the kidney of a male rat. The embryo, and embryonic membranes, are of fairly normal configuration. Note that several cells of the embryonic ectoderm are undergoing mitosis. Autopsy six and a half days after the transplantation of one blastocyst

The homospecific transfer of blastocysts to the kidney in both species further demonstrates the superior ability of the mouse blastocyst to develop in an alien environment (Table 1). Mouse blastocysts are more than four times more successful in 'implanting' on the mouse kidney than rat blastocysts on rat kidney. This proportion of successful rat to rat transplants is very similar to that obtained by Nicholas[5]. My results differ considerably, however, in that he found no invasion of the kidney cortex, no differentiation of the trophoblast, and excessive proliferation of embryonic tissues. I am unable to confirm these findings (Table 1).

The remarkable tolerance of the host to the heterospecific mouse trophoblast may be attributed to two factors. First, the antigenic nature of the trophoblast appears to be weak, although this weakness cannot be ascribed solely to its embryonic character. The transplantation of a 6½-day-old embryo, the associated trophoblast of which has been removed, evokes, in a similar period of time, a strong reaction as manifest by the massive accumulation of leucocytes around the graft. The response to the trophoblast is very much weaker. Secondly, it has been demonstrated recently[6] that the human trophoblast absorbs during pregnancy anti-trophoblastic antibodies. The mouse trophoblast may have a similar function, and any antibodies that are produced would be removed from circulation.

The reason for the failure of the rat trophoblast to proliferate on the mouse kidney is, at present, not clear.

I thank Drs. M. Fischberg and A. W. Blackler for advice. This work was carried out during the tenure of a Ford Foundation research fellowship.

Brood-production after Hypophysectomy in the Viviparous Teleost *Mollienesia latipinna* Le Sueur

Among the predominantly oviparous teleost fishes the habit of viviparity is widespread, and appears to have arisen repeatedly and independently in various families. Details of viviparity are best known for the cyprinodont family Poeciliidae, which includes several popular aquarium fishes such as the guppy, platyfish and swordtail, but even for this group there is very little known about the physiological specializations involved in gestation, which occurs within the ovarian follicle, and in the birth of the young fish[1]. Evidence so far has suggested the involvement of pituitary hormones in these processes[2], but the essential step of hypophysectomy of pregnant females has not been performed, possibly because of the surgical problems inherent in the small size of these fishes. Recently I have developed a technique for hypophysectomy in the poeciliid *Mollienesia latipinna*, which permits removal of the pituitary gland with good survival in fish down to about 35 mm. length. The operation will be described in detail in a later paper, and this communication is concerned only with the salient effects of hypophysectomy on brood production in the female.

A black domesticated variety of *M. latipinna* ('black mollie') was used, and the fish were kept in stock tanks and individually in two-litre jars under conditions of constant temperature (27 ± 1° C.) and illumination (16 hr. a day). Normal fish were kept in dechlorinated Liverpool tap-water, but it was soon found that, like *Fundulus heteroclitus*[3], hypophysectomized mollies cannot live in freshwater. *M. latipinna* is strongly euryhaline[4], and operated fish were accordingly kept in 33 per cent sea water (for up to three months), individuals being acclimatized to this medium for at least one week before the operation.

Under the above conditions, normal females isolated with males in jars repeatedly give birth to broods of between one and 40 young fish at intervals of about 30 days. After a brood has been born, the ovary contains only partly developed oöcytes, some of which then grow rapidly to maturity in five days. When ripe the yolk-filled eggs are not ovulated, but are retained in their follicles where they are fertilized by sperm introduced into the oviduct by the male in copulation. Each embryo then develops on top of its egg within the follicle; when development is completed the follicles rupture (all within an hour or two of each other) and the motile young are freed into the ovarian lumen. Muscular contractions of the ovary and oviduct then expel them to the exterior.

Removal of the pituitary gland from a pregnant female does not interfere with the current brood. On the contrary, the embryos complete their development, are born in the normal manner, and are as lively and survive as well as young fish born to normal females. This conclusion is based on observations of 12 operated females in which hypophysectomy was shown to be complete by total cessation of growth and by the development of acute distress symptoms within 24 hr. after transfer to freshwater. (Sham-operated fish, in which the pituitary gland was exposed but left *in situ*, grew vigorously and lived indefinitely in freshwater.) In addition, the absence of pituitary remnants was confirmed in eight of these hypophysectomized females by examination of serial sections of the middle part of the head. The interval between hypophysectomy and birth of a brood varied from 1 hr. to 26 days. Six other pregnant females which were hypophysectomized either died or were killed before their broods were born, but in every case the ovary at autopsy contained living or newly-dead embryos. In none was there any signs of resorption or death of the embryos as a result of the withdrawal of maternal pituitary hormones.

These experiments have also confirmed that in this viviparous fish, as in oviparous teleosts[5], pituitary function is necessary for the second-phase (vitellogenic) growth of the oöcyte. Early second-phase oöcytes present in the pregnant ovary at the time of hypophysectomy were resorbed at the same time as the embryos were developing although, as in normal females, the occasional fully-grown egg that had escaped fertilization (or in which embryonic development had been arrested) was retained in its follicle and released along with the living young at parturition. Following parturition in hypophysectomized fish the younger oöcytes failed to embark on the normal rapid yolk-accumulation and growth, the ovary thereafter remaining in an immature state with only small pre-vitellogenic oöcytes. In sham-operated females, in contrast, such oöcytes grew after parturition at the same rate as in normal fish.

It appears that in *Mollienesia*, and presumably in the other live-bearing poeciliids, adenohypophysial hormones are directly concerned in oöcyte development but are not involved in maintaining gestation, nor in the ovulation-like release of the young from the follicles. Nevertheless, some kind of humoral coordination of follicular rupture seems to be indicated by the retention of non-fertile eggs and their ovulation at the same time as the motile young fry are expelled from their follicles, and by four cases in which the 'brood', born to normal females at the predicted time, contained only one motile fish together with eggs, partly-developed embryos and dead fry.

Interaction of 6-Methylaminopurine and Adenine in Division of Soybean Cells

Cell division in many cultured plant tissues is known to be promoted by kinetin (6-furfurylamino purine) and related compounds[1]. Among these related compounds is a series of 6-*n*-alkylaminopurines. Tests at the University of Wisconsin with tobacco callus tissue revealed no activity for 6-methylaminopurine (MAP), a slight activity for the ethyl compound, and increasing activity through the series *n*-propyl-, *n*-butyl-, *n*-pentyl-, and *n*-hexylaminopurine, with the hexyl and pentyl compounds giving much the same results; activity then decreased with increasing size of the alkyl group[2]. A similar alignment was obtained for these compounds by Kuraishi[3] using a radish leaf disk test dependent on cell enlargement rather than division. Kuraishi, however, did observe a slight activity for the 6-methylaminopurine. Recently, I have obtained almost identical results for the series in another cell division test[4] which utilizes tissues derived from soybean (*Glycine max*, var. Acme) cotyledons.

I have been particularly interested in MAP since others have reported that it occurs in some soluble ribonucleic acids[5] and since there is considerable evidence that kinetin-type compounds (which may be regarded as derivatives of MAP) may influence growth through effects on ribonucleic acids and perhaps afterwards on protein synthesis. MAP, when added alone to the test medium[4], not only failed to stimulate division of the soybean cells at all concentrations used, but also actually inhibited the growth expected in controls when it was used in fairly high concentrations (exps. *A* and *B*, Table 1). This inhibition was most noticeable when the control pieces showed considerable growth as a result of carry-over of kinetin from the previous medium. That MAP can prevent kinetin-induced growth is evident from exp. *B* of Table 1.

Since MAP is an adenine derivative, I suspected that the methyl compound was inhibiting adenine-requiring processes in the cells. That this probably is so is apparent from the complete reversal of the inhibition by adenine added to the test medium even though adenine itself, being rather erratic in its effects, gave either no promotion or an inhibition (Table 1). The riboside adenosine was as effective as adenine in the reversal and by itself showed little inhibition or a slight promotion. Compounds which were ineffective include hypoxanthine, xanthine, guanosine, caffeine, theobromine, theophylline, cytosine, orotic acid, thymine and uracil.

Table 1. EFFECTS OF MAP, ADENINE AND KINETIN ON CELL GROWTH IN SOYBEAN TISSUES

Concentration of additive (mgm./l.)			Fresh weight per piece (mgm.)	Dry weight per piece (mgm.)
MAP	Adenine	Kinetin		
Exp. *A*, 34 days growth				
—	—	—	214	18
0·14	—	—	213	15
1·49	—	—	199	17
7·45	—	—	111	10

14·9	41	—	548	50
22·3	41	—	789	66
—	—	0·5	1,943	150
—	41	0·5	1,721	142
Exp. *B*, 27 days growth				
—	—	—	54	4
22·3	—	—	37	3
22·3	50	—	841	42
—	—	0·5	973	72
22·3	—	0·5	101	10

Not only did adenine reverse the MAP inhibition, but also the combination of the two caused continuous cell division as though kinetin had been added. The fresh and dry weights resulting from this combination are presented in Table 1; microscopic examination showed that the increased weights were correlated with cell division. Adenosine again was as effective as adenine.

I interpret the results to mean that added MAP has at least two types of action in soybean cells. The compound acts as an inhibitor of certain adenine-requiring processes but also acts as a rather inefficient kinetin-type compound. When a concentration of MAP high enough to cause cell division (in the manner of kinetin) is used, the inhibitory effect is so pronounced that no division takes place. If, however, the inhibition is reversed by adenine, the kinetin-like action becomes quite apparent in terms of cell division. The correlation between activity and the length of the chain in the 6-alkylaminopurines strongly suggests that the alkyl group brings about either a particular distribution or orientation of the compound within the cell and that this is necessary for activity. Thus far, all active kinetin analogues have a fat-soluble group in the 6 position[2]. If such is the only function of the alkyl group, then an assignment of a natural role to MAP is difficult in view of the very high concentrations of the compound required for promotion of cell division. If, however, the alkyl group should be found to have an additional function such as to block the amino group of adenine, we could visualize a critical methylation of adenine already properly located within the cell.

This work was supported by grant *G*9017 from the National Science Foundation. I thank Dr. William Shrive, Dr. F. M. Strong and Dr. Roland Robins for samples of the various purine derivatives.

Effect of Temperature on *in vitro* and *in vivo* Reactions of Diethyl Sulphate

RECENT work[1-3] has established that diethyl sulphate has characteristics which are of special interest to geneticists in many fields of research. These special characteristics include the induction of a high frequency of mutations accompanied by a high survival of the treated population and a low frequency of visible chromosome aberrations[1]. Similar properties have been found for ethyl methane sulphonate, a related alkylating compound[4-6].

The unique properties exhibited by diethyl sulphate can best be understood when they are related to the reaction kinetics of this agent. However, accurate and complete data on the hydrolysis of homogeneous aqueous diethyl sulphate solutions over the temperature range 0–40° C. have not been reported.

The chemical properties of diethyl sulphate have been reviewed by Suter[7]. Hydrolysis occurs in accordance with the equation:

$$\text{step 1: } C_2H_5OSO_2OC_2H_5 + H_2O \longrightarrow C_2H_5OH + C_2H_5OSO_2O^- + H^+$$

$$\text{step 2: } C_2H_5OSO_2O^- + H_2O \longrightarrow C_2H_5OH + SO_4^{=} + H^+$$

To obtain evidence on the quantity and nature of mutagenic substances in diethyl sulphate solutions, it was important to establish whether or not an appreciable amount of ethyl hydrogen sulphate hydrolysed in test periods at 0–40° C. Evans and Albertson[8] showed that the first ethyl group was removed much faster than the second. In our experiments, the rate of hydrolysis of ethyl sulphuric acid (step 2) in the temperature-range 0–40° C. was found to be insignificant. Diethyl sulphate solutions maintained at 30° C. for four weeks before adding barium chloride as a test for sulphate yielded no precipitate. Evidence for a quantitative yield of one mole of hydrogen ion per mole of diethyl sulphate, obtained by titration of hydrolysed solutions with sodium hydroxide to a phenolphthalein end-point, confirmed this result.

Additional experiments on the rate of formation of ethyl sulphuric acid established that the step 1 hydrolysis of diethyl sulphate in acid aqueous solutions over the pH range 1·0–7·0 follows first-order kinetics. Furthermore, the rate of formation of ethyl sulphuric acid was not affected by the accumulation or addition of the hydrolysis products. Similar results were obtained earlier by Kremann[9] in experiments with heterogeneous diethyl sulphate systems. However, he reported a temperature coefficient (Q_{10}) of approximately 4·0 over the temperature range 24–44° C. for the hydrolysis of diethyl sulphate, hence he concluded that the Q_{10} was not influenced by temperature.

In contrast, we found that the Q_{10}, expressed as a ratio of rate constants, was not constant but changed from 4·5 for the 0–10° C. temperature-range to 3·1 for the 30–40° C. temperature-range (Table 1). These values were established from investigations of homogeneous aqueous diethyl sulphate solutions conducted over a wider range of temperatures than used by Kremann. The activation energy values calculated from the rate constants obtained for the *in vitro* reaction were found to range from 23·2 kgm./cal./mol. for 0–10° C. to 21·4 kgm./cal./mol. for 30–40° C. Thus we have established that the *in vitro* hydrolysis Q_{10} is dependent on temperature. This fact must be considered when attempting to evaluate data from biological experiments conducted over a range of temperatures.

Table 1. INFLUENCE OF TEMPERATURE ON THE *in vitro* HYDROLYSIS OF DIETHYL SULPHATE AND ON THE *in vivo* GROWTH REDUCTION INDUCED IN BARLEY SEEDS BY NON-BUFFERED AQUEOUS DIETHYL SULPHATE SOLUTIONS

	In vitro system			*In vivo* system	
Temp. °C.	First order rate constant (min.)	Half-life (hr.)	Hydrolysis Q_{10}	Treatment time* (hr.)	Biological effect Q_{10}
0	$1·95 \pm 0·04 \times 10^{-4}$	59·2		39·0	
5	$4·18 \pm 0·01 \times 10^{-4}$	27·6	4·5		2·69
10	$8·80 \pm 0·08 \times 10^{-4}$	13·1	4·2	14·45	
15	$1·77 \pm 0·02 \times 10^{-3}$	6·53	3·9		2·69
20	$3·45 \pm 0·02 \times 10^{-3}$	3·34	3·6	5·37

30	$1·15 \pm 0·03 \times 10^{-2}$	1·00	3·2	2·0	
35	$2·08 \pm 0·05 \times 10^{-2}$	0·555	3·1		
40	$3·57 \pm 0·04 \times 10^{-2}$	0·323			

* Time of exposure to 0·0076 M diethyl sulphate solutions (changed after 29 per cent hydrolysis) required to obtain the same seedling growth response.

Once this more complete information on the kinetics of the *in vitro* system was available, the use of a relatively constant concentration of diethyl sulphate in treatment solutions was possible. Experiments were then initiated to establish the relationship of the *in vitro* concentration of active mutagen available for reactions with cellular components to the biological response obtained from these reactions in the *in vivo* system. In these experiments, seeds of the hull-less barley variety, Himalaya *C. I.* 620, with 13 per cent moisture, were treated by immersing them in freshly prepared aqueous non-buffered 0·0076 M diethyl sulphate solutions. The solutions were changed at intervals corresponding to the time of 29 per cent hydrolysis in order to maintain the concentration of active agent. Non-buffered solutions were used in order to avoid the complication of extraneous factors in these initial experiments. It had previously been established that barley seeds did not show damage when exposed for even longer periods of time to greater concentrations of the hydrolysis products (pH as low as 1·3) than were used in these experiments. Thus the pH (approx. 2·7) of 0·0076 M diethyl sulphate solutions changed after 25 per cent hydrolysis was not damaging to seeds treated for the period described.

To determine the effect of temperature on the induction of damage to barley seeds, lots of 50 seeds were treated at 0°, 10°, 20°, and 30° C. for varying periods which were estimated first on the basis of the *in vitro* Q_{10}. The seeds were washed for 1 hr. in distilled water at 30° C. after their exposure to diethyl sulphate and then were grown on wet blotters in Petri dishes. After six days at 23° C. under continuous illumination, the height of seedlings was measured and compared with controls.

The treatment times required to retard the growth of seedlings to approximately 63 per cent of the controls was found to vary from 2 hr. at 30° C. to 39 ± 0·4 hr. at 0° C.

The results obtained, confirmed by subsequent experiments, established that the *in vivo* Q_{10} is nearly constant, with values between 2·67 and 2·70 (av. 2·69) for different treatments (Table 1). It follows that the exposure period required to produce a given level of injury to barley seeds by treatment with diethyl sulphate may be calculated according to the formula:

$$t_2 = t_1 \times 2·69 \left(\frac{T_1 - T_2}{10}\right)$$

where t_1 is time of treatment at temperature T_1 and t_2 is time of treatment at temperature T_2.

The nature of the rate-controlling factor mainly responsible for the Q_{10} of 2·69 is under active investigation.

A more extensive comparison of physical and biological data will be published later. Preliminary results of experiments on the mutation response of diethyl sulphate-treated barley seeds, which show the same injury response, indicate that both the frequency and spectrum of mutations recovered may be influenced by the temperature of the treatment solution. Similar work on the kinetics of *in vitro* and *in vivo* reactions of ethyl methane sulphonate is now in progress.

This work was sponsored by research grants from the U.S. Atomic Energy Commission contract *AT*–(45–1)–353, and the National Institutes of Health, grant *A*–2184, and conducted under Washington Agricultural Experiment Stations projects 4068 and 1435. We thank Drs. C. M. Stevens, R. J. Foster, R. R. Legault, and B. A. McFadden for advice.

Fluorophenylalanine as a Systemic Fungicide

In previous publications[1,2] some amino-acids, not naturally occurring, were shown to be chemotherapeutically active against certain fungal diseases of plants. Since no fungitoxic action of the compounds could be demonstrated *in vitro* or in the sap of treated plants, the increase in resistance of the plants might be explained as the result of changes in their metabolism caused by interference of the foreign substances.

We have found that both DL-*p*- and DL-*m*-fluorophenylalanine can protect cucumber seedlings against *Cladosporium cucumerinum* and *Colletotrichum lagenarium* in concentrations of 0·0050 and 0·0025 *M* applied to the roots before inoculation. The roots sometimes show some loss of turgescence, while higher concentrations also affect the green parts. DL-*o*-fluorophenylalanine appears to be more phytotoxic and to have a smaller protective effect.

Fluorophenylalanine, being an amino-acid not found in plants, might be expected to have an indirect effect like the amino-acids mentioned before, for example, D-serine. It is known, however, that fluorophenylalanine inhibits growth of some micro-organisms[3] and its effect on spore germination and mycelium growth was investigated *in vitro*. Using the paper disk bioassay with *Cladosporium cucumerinum* as a test fungus an inhibition zone of 30 mm. was found for a solution of 250 p.p.m. *p*-fluorophenylalanine or *m*-fluorophenylalanine, while *o*-fluorophenylalanine in the same concentration and under the same conditions produced only a zone of scanty growth. A similar difference in toxicity could be demonstrated for *Glomerella cingulata* and *Aspergillus niger*. The latter did not germinate on plates of a glucose-mineral salts agar containing more than 5 p.p.m. *p*- or *m*-fluorophenylalanine, but 50 p.p.m. *o*-fluorophenylalanine did not inhibit germination.

From these results it seems likely that the influence of the fluorophenylalanines on the development of fungal diseases is due to their fungitoxicity and not to some indirect effect. This was examined further by expressing sap from the hypocotyls of cucumber seedlings—the part of the plants which is most affected by *Cladosporium cucumerinum* and *Colletotrichum lagenarium*—and testing its fungitoxicity by means of the paper disk bioassay. Sap of plants treated via the roots with *p*- or *m*-fluorophenylalanine produced distinct inhibition zones about 45–60 mm. in diameter, but sap of plants treated with *o*-fluorophenylalanine had no effect or only produced a zone of decreased growth. This is in good agreement with the results of the experiments on the activity of the different compounds *in vitro* and in plants, and may indicate that the latter is due to the former.

According to Mitchell and Niemann[3], fluorophenylalanine is an antimetabolite of phenylalanine. This was confirmed in our experiments *in vitro*. The growth inhibition caused by all three fluorophenylalanines could be completely antagonized by adding L-phenylalanine in a concentration twice that of the fluorocompound.

However, treatment of plants with a solution containing fluorophenylalanine (*p*-, *m*- or *o*-) together with phenylalanine in the same or a higher concentration had a similar effect on the disease as a solution of the first substance alone, although addition of phenylalanine seemed to decrease the injury to the plants, especially to the roots. Sap of plants treated with both amino-acids was not fungitoxic in the paper disk bioassay, but when this sap was chromatographed according to Dekhuijzen's method[4] inhibition zones were found with the same R_F as fluorophenylalanine. Apparently fluorophenylalanine is present; but its fungitoxicity is antagonized by some compound of the sap, presumably phenylalanine. This seems to contradict the conclusion that the increase in the resistance of the plants is due to fungitoxic properties of the sap after treatment. The inconsistency can be explained if we assume that there is a difference in the distribution of the two substances among the various tissues of the intact plant. This means that at the spot where fluorophenylalanine exerts its influence on the fungus, the concentration of phenylalanine is too low to reverse this effect. In expressed sap, of course, the contents of all cells are pooled.

To test this hypothesis we looked for a more homogeneous tissue for treatment with fluorophenylalanine and phenylalanine and inoculation with fungus. Disks of potato tuber, var. Bintje, 8 mm. in diameter and 0·5 mm. thick, proved to be suitable for this purpose. The disks were floated in aerated solutions for 24 hr., rinsed with water, dried with filter paper, placed on moist filter paper in Petri dishes and inoculated with a suspension of zoospores of *Phytophthora infestans*. After 5–6 days at 20° C. all control disks were covered with mycelium, whereas only a few of the disks treated with fluorophenylalanine showed some growth. Here the best effect was obtained with *o*-fluorophenylalanine 0·0050 or 0·0025 *M*; *m*-fluorophenylalanine had less and *p*-fluorophenylalanine had scarcely any effect. The protective effect disappeared almost entirely when phenylalanine was added to the solutions.

The fact that both the fungitoxic and the protective effect of the fluorocompounds can be reversed by phenylalanine renders it probable that the first is responsible for the second. The possibility that a change in the metabolism of the host cells is also antagonized by phenylalanine cannot be ruled out, however. It should be mentioned that Samborski and Forsyth[5] found inhibition of rust development on wheat leaves floating on solutions of *p*-fluorophenylalanine, which effect was reversed by phenylalanine.

A difference in sensitivity of the various fungi is probably responsible for the fact that the *o*-isomer was most active in the potato experiments. Because of the difficulties involved in growing *Phytophthora infestans* on simple synthetic media data about its sensitivity are lacking, but mycelium growth of two other Phycomycetes, *Phytophthora cactorum* and *Pythium debaryanum*, was more inhibited by *o*- than by *m*- or *p*-fluorophenylalanine.

The results mentioned here indicate that fluorophenylalanine acts in a different way from the other amino-acids and their derivatives investigated before. In the latter case the effect seems to be indirect, while the fluorocompounds probably behave as real systemic fungicides.

Preparations of Cell-Walls of Some Fungi

LITTLE is known of the qualitative and quantitative composition that may occur in the cell wall of fungi. Cochrane[1] has claimed that the most serious defect in our knowledge of cell-wall composition in the filamentous fungi is the fact that no 'pure' wall material is yet available. The major sources of error are the inclusion of extraneous substances in the preparation, and the loss of wall material during purification. Several workers have described results of the cell-wall composition based on X-ray diffraction patterns. Results from other methods (isolation of derivatives from a hydrolysate, microchemical tests, etc.) are usually in agreement with those of X-ray analysis, but are in most cases unsatisfactory.

This communication describes a method for the isolation of cell-walls of various moulds. Organisms were grown in Czapek medium shaking at 25° for 48 hr. avoiding sporulation. The resulting mycelium was then collected in a centrifuge and washed three times with water. After resuspension in water the mycelium was partially disintegrated by means of concentric ground-glass cones, washed five times and treated with ethyl ether for 1 hr. A serious difficulty occurred when attempting to disintegrate mycelium before treatment with ethyl ether. The resulting mycelium was washed with water and cell-walls were prepared by the method of Salton and Horne[2], by using the Mickle disintegrator. 10 ml. of the partially broken mycelium suspension were added to each cup of the machine and shaken with 10 ml. of grade 12 Ballotini glass beads for 4 hr. at room temperature. Breakage was followed by microscopic examination of lactophenol blue stained material.

After breakage, intact mycelium and debris were removed by centrifugation at 500*g* and the supernatant was transferred into a narrow glass tube (3 × 100 mm.) and the contents spun down at 1,000*g*. The sedimented material, containing unbroken cells, was discarded. The supernatant suspension was then centrifuged at 5,000*g* for 20 min. to sediment the cell-wall fraction. This material was digested first with crystalline trypsin and then with pepsin, as described by Villanueva[3]. The digest was centrifuged at 5,000*g* and washed once with 1 *M* sodium chloride solution, the precipitate being re-suspended in water and thoroughly washed. The purity of the preparation was checked by light and electron microscopic examination.

Some Fossil Chelonian Fragments from Makapansgat

THE fossil chelonian material loaned to me by Prof. R. Dart, of the University of the Witwatersrand Medical School, for examination consists of 36 fragments from the early Middle Pleistocene grey breccia of Makapansgat Limeworks in the Transvaal. This fossil material was compared with complete and fragmented skeletal material of *Testudo pardalis babcocki*, *Kinyxs belliana belliana* and *Pelusios sinuatus*, all of which occur in the area to-day. The fossil fragments were all from large animals and none was referable to the genera *Chersina*, *Psammopbates*, *Homopus* or *Pelomedusa*, which were also available for comparison.

Twenty-four bone fragments were assigned to *Testudo pardalis*, representing a minimum of eight individuals, but only two fragments are definitely from the same specimen. Most of the material is derived from large animals (exceeding 12 in. in length and 20 lb. in weight) and the majority of the fragments are from the plastron, particularly the thickened gular area. The frequency of occurrence for the various bones is as follows :

Carapace	5th neural	1
	pleurals	4
	pygal	1
Plastron	epiplastra	9
	entroplastra	2
	hyoplastra	3
	hypoplastra	5
	xiphiplastra	3

One bone fragment consists of the gular section of the epiplastra of a moderate sized chelonian which may be *Kinyxs* sp. Unfortunately, there are no other fragments to establish the presence of this genus.

Three plastron fragments are assigned to *Pelusios* sp. They are from a large terrapin(s) comparable in size with *Pelusios sinuatus*.

Six small fragments could not be assigned to any form with confidence. No less than 22 of the 28 fragments identified were from the plastron.

The two terrestrial forms, *Testudo* and *Kinyxs*, are both widely used as food by man to-day, the former being prized because of its large size. The hinged terrapins (*Pelusios*) are aquatic animals, but are often caught on rod and line and are eaten by many Africans. There seems to be little doubt that the chelonian fragments dealt with here are from in-

dividuals eaten by *Australopithecus*. There are no marks of carnivore teeth on the fragments, and the fracturing could have been caused by smashing the reptiles against rocks. Stone age man would have simply chopped through the bridge between plastron and carapace. The only carnivore which habitually preys on large tortoises is the hyæna, which devours them in the open, being unable to carry a large *Testudo pardalis* in its jaws. I have examined many live tortoises bearing deep marks of carnivore teeth, indicating that the shell is not easily broken open.

I thank Prof. Raymond A. Dart for the loan of this material from the Bernard Price Institute and D. K. Blake for assistance in preparing the necessary comparative material and comparing the fossil bone fragments with modern bones.

MICROBIOLOGY

Morphology of Bacteria treated with Colicin

COLICINS, like bacteriophages, are strain-specific as to their effect. Fredericq[1] proved that specific receptors in the cell wall are necessary for their fixation on the cell. It is interesting that, in my experience, the specificity of colicins is considerably lower than that of *coli*-phages.

Immediately after the fixation of the colicin *ML* on sensitive bacteria, the increase of respiration intensity of the culture, synthesis of both nucleic acids and, in accordance with these, also the growth of the culture are inhibited. After 20 min. the respiration begins to slow up and at the same time the optical density of the culture slightly decreases[2]. I noticed that the cells exposed to colicin quickly lose their reproduction ability and even when washed with broth and re-inoculated on highly nutrient agar they do not form colonies.

In my morphological studies I observed sensitive cells of the strain B_1 on the surface of agar blocks saturated with colicin 18 (ref. 3). The preparations framed with paraffin were observed and photographed in Zeiss phase contrast microscope, using the 1,350-fold direct magnification. From the cells, exposed to the colicin on agar plates for 6 and 48 hr., electron-microscopical preparations were made as well. These cells were, after being washed, gathered on 'Formvar' membranes, shadowed with wolfram-oxide and ob-

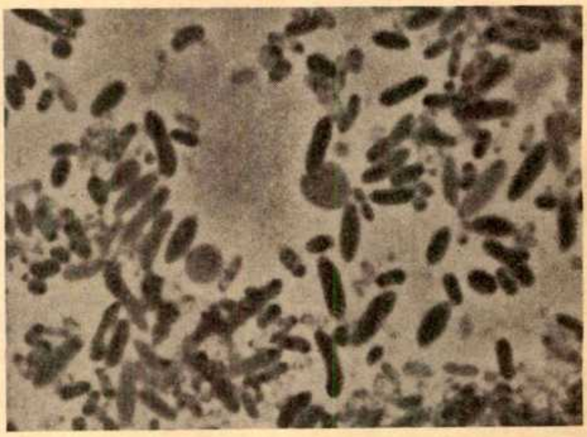

Fig. 1. Sensitive cells of the strain B_1, 26 hr. after contact with colicin. (Phase contrast. × 2,390)

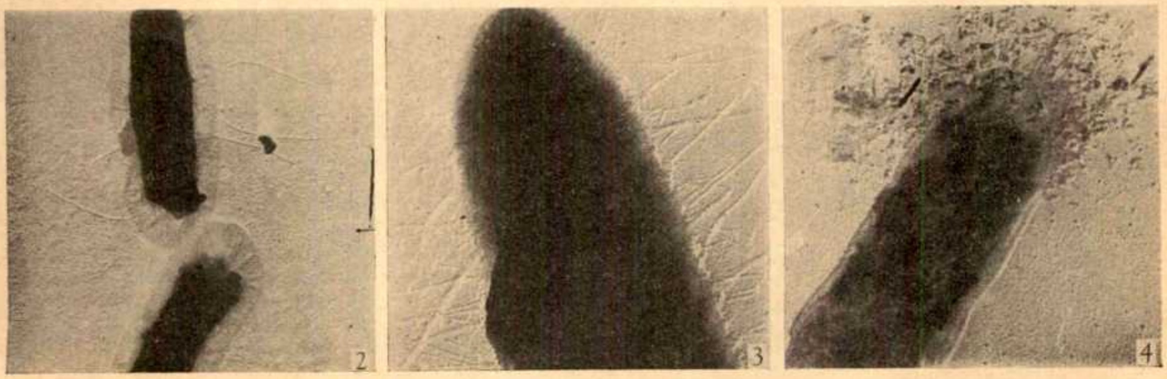

Figs. 2, 3, 4. Cells of the strain B_1. Electron microscope. × *c*. 10,660. 2, Normal cells (control); 3, swollen cell 6 hr. after contact with colicin; 4, lysing cell 6 hr. after contact with colicin served and photographed in a 'Tesla *BS*' 242 electron microscope using the 10,000-fold magnification.

The results in the phase contrast microscope show clearly that the growth and reproduction of sensitive cells stop immediately after the contact with colicin; even the cells which were treated with colicin just in the state of division do not continue to divide. Otherwise no immediate changes were noticed. After about 20 min., however, their volume begins to increase noticeably, they do become more or less round and at the same time their refraction sinks; they swell (Fig. 1). On electron micrographs of these cells it is scarcely possible to distinguish the characteristic edge of the cell wall, typical for such micrographs of normal bacteria (Figs. 2 and 3). The cells continue to swell slowly and the proportion of swelling cells increases until the cell walls burst and protoplasm flows out of them (Fig. 4). At last empty cell walls remain in the preparations.

Controls, that is, non-sensitive cells of *E. coli*, show under the same conditions no morphological changes and multiply quite normally.

With respect to the immediate inhibition of growth and division of the cells by colicin it is possible to assume that colicin kills them by disturbing some elementary physiological reaction; the swelling of the rods is one such result.

I performed similar experiments with spheroplasts of sensitive and resistant cells, using penicillin. Colicin acts on spheroplasts of sensitive cells similarly as on the cells themselves. The order of morphological changes is similar to that of the cells; it just proceeds more quickly. For 8 hr. the majority of swollen spheroplasts suddenly burst and disappear. The higher rapidity of swelling may be caused by the fact that the spheroplast wall is less firm than the cell wall because it lacks the rigid layer[4].

The spheroplasts of resistant cells are not affected by colicin at all: they multiply and regenerate into rods.

These results indicate that the weakened wall of penicillin spheroplasts still contains specific receptors for colicin 18.

CYTOLOGY

Ozone-induced Chromosome Breakage in Human Cell Cultures

OZONE-INDUCED effects in biological systems may be particularly significant in radiation biology. The decomposition of ozone in water produces the same active radicals (OH and HO_2) which are generally considered the biologically active products of irradiation of protoplasm. Phillips[1] has reported on the effects of active radicals chemically produced by the catalytic decomposition of hydrogen peroxide with ferric ions; this system, however, has a low radical yield, as was evidenced by the extremely low frequency of chromosome aberrations produced over a wide range of reactant concentrations.

The ozone system produces a much higher concentration of these active radicals and in the presence of positive pressures will establish an equilibrium reaction with the hydroxyl ions in solution continuously to produce active radicals so long as the ozone is present[2]. A previous report[3] indicated that exposure of *Vicia faba* to ozone resulted in a high frequency of chromosome aberrations in root meristems. The investigations reported here are an extension of this work to demonstrate the activity of ozone against human cells in culture.

The *KB* human cell line[4] used was grown in Eagle's media[5] and incubated at 35° C. Before exposure to ozone, cells were washed once in a protein-free saline solution to remove extraneous reducing materials. Ozone is very reactive, and small amounts of reducing materials provide considerable protection. After rinsing with saline the bottles were rotated so that the cells were at the top of the flask and any saline would drain to the bottom. The ozone–oxygen mixture was allowed to flow into the bottle continuously in a closed system at a rate of about 100 ml./min. Ozone was produced with a laboratory ozonator (Wellsbach Co., model *T* 22) from cylinder oxygen and the concen-

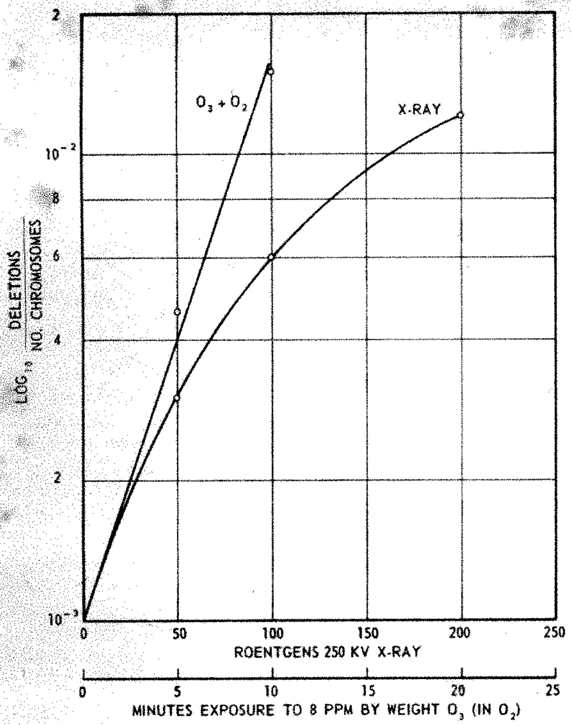

Fig. 2

tration calculated by scrubbing replicate samples of known volume through 2 per cent potassium iodide (*p*H 9), acidifying the solution and then titrating with 0·1 *N* sodium thiosulphate[6]. After exposure to ozone the culture bottles were rinsed with saline and then replaced with a medium containing 2 mgm./l. colchicine. Cultures were incubated for 24 hr., hypotonically treated for 20 min. (20 per cent strength medium), agitated to dislodge the metaphase cells[7] and then fixed by the addition of propionic acid to a final concentration of 25 per cent. With this technique all the metaphase chromosomes analysed were dosed with ozone since their last metaphase—the duplication time of these cultures being approximately 33 hr. The fixed cell suspension was concentrated by centrifugation, air-dried on slides, stained with propionic orcein and made permanent with the dry-ice technique. A number of different types of chromosome damage was investigated and chromatid breaks were selected as the criteria of choice. This type of aberration is a random event requiring a single hit and may be assumed to be independent of other chromosomes in the cell for its expression. The variable chromosome number characteristic of adapted cell lines makes the analysis of chromosome type of aberrations unlikely; but with chromatid breaks the culture may be treated as a population of chromosomes. The type of effect reported is shown in Fig. 1. *A* shows a typical metaphase figure and *B* demonstrates chromatid deletions in two different chromosomes.

Table 1

Experimental group	No. of chromosomes	Deletions	$\frac{\text{Deletions}}{\text{No. chromosomes}}$

* S.E. $= \sqrt{\frac{A}{N}}$, where $A = \frac{\text{deletions}}{\text{chromosome}}$ and N = No. of chromosomes.

† Parts per million by weight.

Table 1 and Fig. 2 present the results of exposing cultures of *KB* cells to 8 parts per million by weight of ozone in oxygen for 5 and 10 min. Higher concentrations of ozone or longer exposure times with this concentration resulted in the cells dislodging from the glass surface, rendering the preparation unfit for analysis. For comparison, cultures were exposed to 50, 100, and 200 r. of 250-kV. X-rays and treated in the same manner as the ozone-exposed cultures.

Chromatid deletions were produced as an exponential function with exposure to ozone. This would be in agreement with the concept that chemically produced active radicals would be dependent for expression on penetration to the chromosomes. This would therefore be a function of concentration and would obey the law of mass action. Such an exponential response has also been interpreted as evidence of a direct action type of effect[8]. The production of chromatid breaks with X-ray follows a linear relationship or 1-hit kinetics as has been demonstrated in many other systems and is usually interpreted as a function of the random distribution of active radicals produced by the radiolysis of water throughout the protoplasm of the cell. This investigation has demonstrated that exposure to ozone is capable of producing chromatid breakages in human cell cultures which are apparently identical to those produced by X-rays. The difference in time-concentration response between ozone exposure and X-rays may be explained in terms of penetration.

These investigations were supported by grant No. *RG.* 4722 of the U.S. National Institutes of Health.

Isolation of Synaptic Vesicles from Nerve Endings of the Rat Brain

SINCE the discovery of 'synaptic vesicles' as a specific component of synapses[1,2] it was suggested that they could be associated with the storage and possibly with the synthesis of transmitter substances. This concept was supported by degeneration experiments[3] and specially by the stimulation of some cholinergic terminals[4], which suggested that within the ending a balance exists between the formation and release of synaptic vesicles. However, the isolation of such a sub-cellular component remained as the most direct approach to the elucidation of the physiological significance and chemical nature of these vesicles.

Recently[5], we demonstrated that the so-called mitochondrial fraction of the brain contained, besides free mitochondria and myelin, a considerable number of isolated nerve endings, and it was postulated

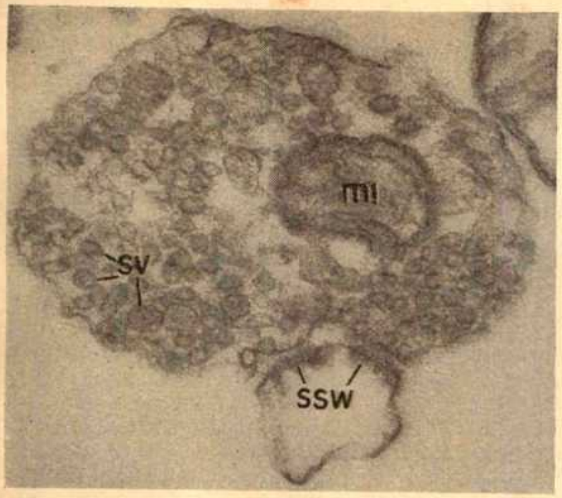

Fig. 1. Nerve ending isolated from the rat brain in fraction *M*. *Mi*, Mitochondria; *SV*, synaptic vesicles; *SSW*, subsynaptic web. Pellet fixed in osmium tetroxide, embedded in methacrylate and sectioned. (× *c*. 83,000)

that this fraction could provide a good starting point for the isolation of 'pure' synaptic vesicles. Independently, Gray and Whittaker[6] published similar observations of nerve endings in the primary mitochondrial fraction of the brain and were able to separate them from myelin and free mitochondria.

More recently, a technique was developed in our laboratory by which the mitochondrial fraction (M) could be fractionated further into five fractions which in order of increased density were: A, myelin; B, fragments of endings and membranes; C, cholinergic nerve endings; D, non-cholinergic nerve endings; and E, free mitochondria[7].

The two sub-fractions C and D of nerve endings provided the starting point for the isolation of synaptic vesicles; but these endings were found to shrink in the hypertonic sucrose, and it was observed that treatment with isomolar sucrose, when prolonged, interfered with the liberation of the synaptic vesicles. On the contrary, the freshly prepared endings of the primary mitochondrial fraction M (ref. 7) showed an excellent preservation and different osmotic behaviour. As shown in Fig. 1, such an isolated ending has a limiting membrane within which there are one or more mitochondria and numerous synaptic vesicles. In addition to the pre-synaptic membrane, a portion of the post-synaptic membrane and the sub-synaptic web are attached[8]. The complex formed by the two synaptic membranes is held together by a system of fine intersynaptic filaments[8].

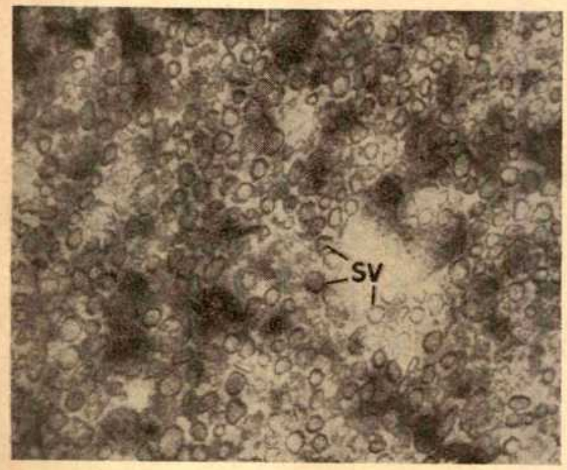

Fig. 2. Synaptic vesicles present in subfraction M_2 after osmotic disruption of nerve endings of fraction M. Pellet fixed in osmium tetroxide, re-suspended in phosphotungstic acid at *p*H 6·8 (negative staining, ref. 9) and observed under the electron microscope. Photographic inversion of the electron micrograph to make easier comparison with Fig. 1. (× *c*. 97,400)

If such isolated nerve-endings are submitted to an osmotic shock in distilled water, the outer membrane of the ending is ruptured, and the synaptic vesicles are liberated. By centrifugation of the osmotically shocked mitochondrial fraction (M), three sub-fractions can be obtained (Table 1) of which M_2 is composed mainly of synaptic vesicles (Fig. 2) and some curved membranes. Fraction M_1 contains myelin fragments, swollen mitochondria and disrupted nerve-endings in which the components of the membrane complex, but not the synaptic vesicles, can be recognized. Table 1 shows the relative distribution of protein and succinodehydrogenase in the three sub-fractions of M. The fact that practically all the succinodehydrogenase is in M_1 demonstrates that the osmotic shock has not so disrupted the mitochondria as to liberate this enzyme.

Table 1. PERCENTAGE DISTRIBUTION OF SUCCINODEHYDROGENASE AND PROTEIN IN THE SUBFRACTIONS OF *M* AFTER OSMOTIC SHOCK IN DISTILLED WATER

M_1 sediment centrifuged at 11,500g for 20 min., M_2 sediment centrifuged at 100,000g for 30 min., M_3 supernatant of M_2

	M_1	M_2	M_3
Succinodehydrogenase	97·2	2·8	—
Protein	71·2	12·4	16·4

Morphologically, the vesicles are similar to those found within the isolated nerve-endings and in sections of the brain cortex. They have a mean diameter of about 500 Å. and comprise a definite membrane surrounding a cavity. This is demonstrated by negative staining with phosphotungstic acid which penetrates into the osmotically shocked vesicles (Fig. 2).

At high magnifications small openings or pores through which the phosphotungstic acid may have entered the vesicles can be observed. Such discontinuities could be due to the drastic osmotic treatment. Work is being carried out to liberate the vesicles by milder treatment. In such preparations investigations are under way to determine the distribution of acetylcholine, and other transmitters and the enzymes involved in their metabolism.

Adrenal Cytology of South Indian Anurans

During the course of investigations on structural variation among the endocrine glands of anurans the pituitary and the adrenal have shown some interesting features with regard to their cell types. The cytology of the pituitary gland, with special reference to the green-frog *Rana hexadactyla*, has been reported previously[1].

In the local species of frogs and toads the adrenal shows the usual interspersed nature of the cortical and medullary components, without any zonation in the cortex. In the cortical cords some of the cells appear blue with Mallory's triple stain and the same cells appear deep magenta in periodic acid – Schiff reaction. These cells are scattered and are occasionally seen in groups of two to three cells. The skipper-frog (*Rana cyanophlyctis*) adrenal shows few periodic acid – Schiff-positive cells while that of the bull frog (*Rana tigrina*) discloses plenty. In the green frog Mallory preparations fail to reveal any blue cells but show light brown ones which are periodic acid – Schiff-positive; the cell outline is either round or oval, but always with the nucleus situated eccentrically. These features correspond with the Stilling cells or eosinophilic cells of the other frogs[2]. These cells contain a mucoprotein which is diastase resistant. They also exhibit a faint metachromasia with toluidine blue or methyl violet. Burgos[3] considers them to be eosinophilic cells which increase in number after hypophysectomy and decrease for pituitary injections. It is found that the periodic acid – Schiff-positive cells which stain blue with Mallory's triple stain are not present in the terrestrial forms *Bufo melanostictus*, *Uperodon systoma* and *Kaloula* sp. In one or two preparations some of the cortical cells of the toads show few minute spherical granules which are periodic acid – Schiff-positive but no blue or magenta red cell occurs. The Stilling cells do not show definite seasonal variation. As yet no one has ascribed the functional role of the Stilling cells. Since the Stilling cells are found only in the aquatic forms and absent in the terrestrial forms, perhaps they may have some importance in the habitat. Hence it has been planned to study the adrenal gland changes, tadpoles and metamorphosis of aquatic and terrestrial forms, which may give some clue to the functional role of Stilling cells.

The other type of cells present in the cortex are mostly cuboidal or elongated and contain lipid droplets of varying size. These cells exhibit cyclical variation in different seasons of the year. It is noticed that there is a regular sequence of storage and elaboration of the lipoid material in all the frogs and toads examined in the present study. These changes appear to be correlated with the changes in the pituitary and the gonad. Active secretion of the lipoidal cells appears to be associated with cytoplasmic vacuolation which reaches a maximum during the pre-spawning months. It has been demonstrated that corticosterone and hydrocortisone are present in the blood[4] and aldosterone in the adrenals[5] of anurans. The former two hormones can bring about ovulation in lower vertebrates[6]. The supporting role of cortisone in anuran ovulation has already been reported[7,8]. Hence, it seems probable that the lipoid droplets of the adrenal cortex of the anurans store potential precursor materials which may be converted into substances of metabolic importance, in response to specific stimulus possibly from the pituitary gland[9]. The adrenal gland of anurans does not show the presence of ascorbic acid, the role of which is debatable.

The ratio between the cortical and medullary components of the anuran adrenal varies in different species. The two components can be distinguished by the so-called chromaffin reaction or by the light-green method of Ira-Ray and Sinha[10]. The cortical tissue constitutes the greater part of the adrenal in all the forms except the green frog in which the medulla appears to predominate.

Two important inferences are made from the seasonal studies of the anuran adrenal glands. First, the Stilling cells are present in all the aquatic forms and are absent in the terrestrial forms; the Stilling cells do not show any seasonal variation. Secondly, the lipoidal cells of the cortex contribute some factor which aids in the growth and maturation of gametes. A detailed report of the changes in the pituitary, gonad and thyroid in relation to the adrenal changes during different seasons of the year will be published elsewhere.

GENETICS

Slow and Fast Transferrin Variants in the Same Pedigree

By means of starch-gel electrophoresis Smithies[1,2] demonstrated the occurrence of distinct fast and slow variants of transferrin, the iron-binding β-globulin fraction of human serum. Several different electrophoretically distinct transferrin components have been identified. They are termed in order of electrophoretic mobility towards the anode B_0, B_{0-1}, B_1, B_2, C, D_0, D_4, D_1, D_2 and D_3. The discovery of the type D_4 by Harris, Penington, Robson and Scriver[3] after all the other D types is the reason for the use of the designation D_4 for a transferrin migrating between D_0 and D_1. Parker and Bearn[4] designated as B_{0-1} the new variant which they recently found with a mobility intermediate between B_0 and B_1.

Family studies[2,5–7] have indicated that the different transferrins were genetically controlled by a number of autosomal genes. Individuals with two transferrin components, say, B_2C, are heterozygous for the genes controlling the B_2 and C variants, while individuals with one transferrin component only are homozygous for the corresponding gene. The phenotype B_2C occurs with a frequency of around 1 per cent in Europeans. In African populations and Australian aborigines the type CD_1 occurs

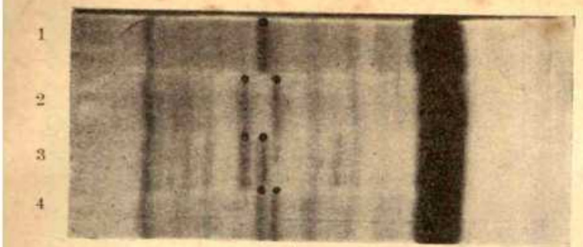

Fig. 1. Photographs of starch gels stained with amido-black 10 *B*. 1, Father $Tf\ C$; 2, mother $Tf\ B_2D_1$; 3, daughter $Tf\ CD_1$; and 4, daughter $Tf\ B_2C$. Transferrin components are indicated by black dots

in a rather high frequency[8]. The remaining phenotypes appear to be rather rare.

So far 10 transferrin components and 12 different phenotypes have been found[4]. Homozygous individuals for aberrant transferrin have been found for the B_1 and D_1 variants. The first frequency studies seemed to indicate that fast variants occurred only in European populations and slow variants only in Africans and Australian Aborigines. Beckman and Holmgren[9] have observed about 2 per cent of the type CD_1 in Swedish Lapps, however, and in a survey of the Swedish population Beckman, Holmgren and Mårtensson[10] found both slow and fast variants. Out of these 25 heterozygous types 18 were B_2C, 4 B_1C and 3 CD_1.

The families of some transferrin heterozygotes found in a sample from Uppsala were examined. Starch-gel electrophoresis of the sera was carried out using a discontinuous buffer system (cf. Beckman and Holmgren[9]). One of these families showed a rather remarkable result.

The proband had the transferrin type CD_1. It was found that a sister of the proband was B_2D (Fig. 1). The father had the normal phenotype C and the mother showed a very rare phenotype, namely, B_2D_1. This female should be the offspring of a mating $B_2C \times CD_1$.

To my knowledge this is the first case where slow and fast transferrin variants have been found segregating in the same pedigree, an observation which greatly strengthens the presumption that the transferrin variants are controlled by alleles at a single locus.

X-ray Sensitivity of Spermatogonia and Spermatozoa in *Drosophila melanogaster*

In a study of X-ray induced crossing-over in young spermatogonia of *Drosophila melanogaster*, Sävhagen (unpublished) has irradiated 17-hr.-old larvæ. These were heterozygous for a series of recessive marker genes in the third chromosome. After eclosion the males were tested during six successive mating periods of three days each. The frequency of males with cross-overs among their progeny decreased for every period. Synchronously the frequency of cross-over per male with cross-overs increased. In all these mating periods the frequency of cross-overs of the total offspring was the same.

The present investigation has been performed in order to clarify if, after irradiation of young spermatogonia, other mutations behave in a manner similar to that shown by the results of Sävhagen. By working with recessive lethal mutations in an autosome the advantage is gained that it can be confirmed with certainty when clusters appear.

The stocks used were one of wild-type (Canton *S*) and one with $al^2\ Cy\ lt^3\ L^4\ sp^2/Pm$. In order to make the second chromosomes isogenic and for lethal testing the CyL/Pm technique was applied. From the wild-type stock one chromosome, free from lethals, was isolated which, when homozygous, provided the flies with a good viability. This chromosome was used in all experiments and was made isogenic at regular intervals in order to avoid spontaneous lethal mutations as much as possible. In every experiment a dose of 900 r. was used. Spermatogonia were irradiated in larvæ, and after eclosion the males were mated in two periods for lethal tests. As material for comparison of lethal frequencies of spermatogonia, spermatozoa in adult males have been irradiated and the frequency of lethals has been stated. In Table 1 it can be seen that the rate of chromosomes with lethals is about three times higher after irradiation of spermatozoa than after the same treatment of spermatogonia. It is true that these stages have been irradiated in different phases of development of the animal. However, Khishin[1] has shown that the sensitivity of the germ cells seems to be independent of their biological environment, and, for that reason, the foregoing comparison should be justified.

Table 1

Stages of germ cells and individual at irradiation	Spermatozoa adults (3–4 day old)	Spermatogonia larvæ (17 hr. old)	
Mating period and type of mating	0–4 hr. after irradiation mass mated	0–3 days after eclosion individually mated	15–18 days after eclosion individually mated
Total No. of tested chromosomes	5·589	7·076	6,021
Total No. of chromosomes with lethals	291	130	94
Chromosomes with lethals/tested chromosome ($\times 10^{-4}$)	521	184	156
Independently induced mutations/tested chromosome ($\times 10^{-4}$)	—	168	111
Chromosomes with lethals/independently induced mutation	—	1·09	1·40
No. of tested chromosomes/male	—	11·4	11·6

Muller[2] has obtained quite a diverting result after irradiation of adult males (3,000 r.). The frequency of lethals in the second chromosome is, according to his work, almost fourteen times greater in spermatozoa than in spermatogonia. Muller's material for irradiated spermatogonia is rather small, and he has not shown if the number of the reported lethals was independently induced or if all chromosomes with lethals are included, thus counting clusters as separate lethals.

In Table 1 it may be seen that a higher rate of independently induced lethals and a lower rate of clusters was found in the mating period 0–3 days than in the mating period 15–18 days after eclosion of irradiated larvæ, while there is no significant difference in the rates of chromosomes with lethals. The results agree then very well with those of Sävhagen on induced crossing-over.

As an explanation of her results, Sävhagen has proposed that primary spermatogonia at division are not always the source of one primary and one secondary spermatogonial cell, as suggested by Tihen[3], but may divide into two primary or into two secondary spermatogonia. Those which have divided into two primary spermatogonia may later divide in a similar manner into two primary or two secondary cells or they may follow the stem cell type of division into one primary and one secondary cell. These later divisions should occur at random and then it would be very possible that some of the mutant spermatogonia would disappear from the testes and some which remained could be the source of large clusters in later mating periods.

Another explanation of the results of Sävhagen and of this work could be that there is some kind of selection mechanism in the spermatogonial tissue. If so this should be reflected in the selective values of the heterozygotes of lethals which have been found following different occasions of irradiation and mating. In order to try to throw light on this problem persistency tests of different lethals which have been found in this experiment are now being carried out.

BUILDING RESEARCH

Bond of Galvanized Steel Reinforcement in Concrete

GALVANIZING is at present being advocated as a means of combating corrosion of reinforcing steel in concrete, and galvanized high-tensile wire is already being used extensively in stressed concrete structures. A survey of existing literature on this subject yielded little useful information, except that various investigators have reported widely divergent results, often in direct conflict.

Thus, Robinson[1] showed that the average bond stress of ½-in. galvanized steel bars in concrete, at failure, was 54 per cent of that of rusty bars. For ⅜ in. rods the figure is reduced to 41 per cent.

D. A. Lewis and J. A. P. Laurie (private communication, 1958), on the other hand, reported the bond-strength of ⅜ in. galvanized reinforcement and that of black or pickled steel, after 9 months' exposure, to be very similar.

Recent experience, during the preparation of prestressed concrete beams, has been equally confusing. Using a galvanized high tensile wire *A* (coating weight 1·00 oz./sq. ft.) as prestressing reinforcement, very little bonding was obtained, the concrete immediately surrounding the wire being spongy. Extensive cracking occurred when external stress was released. Wire *B*, however, with only 0·5 oz. of galvanizing per sq. ft., did not show this tendency. Fig. 1 illustrates this.

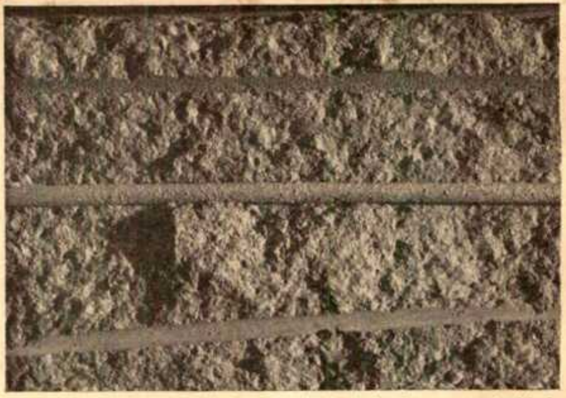

Fig. 1. Concrete in which galvanized steel wires are embedded. Top, Spongy concrete surrounding wire *A*; middle, wire *A* in position; bottom, normal concrete surrounding wire *B*

Initial laboratory experiments indicated that, when pure zinc is immersed in Portland cement extract of *p*H 12·8, no hydrogen is liberated. As soon as a piece of clean steel is brought in contact with the pure zinc under these conditions, however, hydrogen is liberated cathodically on the steel.

From this it was deduced that iron, of relatively low hydrogen overpotential, exposed to wet fresh concrete, either as zinc–iron alloys or at imperfections in the zinc coating of a galvanized rod, would lead to hydrogen evolution which would impair the bond. Tests were carried out to substantiate this theory.

Microscopic inspection of cross-sections of the wires *A* and *B* showed clearly that, while the outer layer of the galvanized coating on wire *B*, although thin, consists essentially of pure zinc, the coating on wire *A* is comprised almost entirely of zinc–iron alloy.

Micro-hardness test results, together with micro-section photographs, showed that the coating on the galvanized bars with a specified coating of 2·0 oz./sq. ft. used by Lewis and Laurie in their experiments had a substantial outer layer consisting mainly of pure zinc. When embedded in concrete no loss of bond due to hydrogen liberation resulted, confirming their original results. When similar bars, which had previously been anneeled at 400° C. for 2 hr. to allow alloy-formation to extend to the coating surface, were placed in concrete, hydrogen was evolved with resultant disruption of the bond.

When the galvanizing on unannealed rods was removed by filing to expose steel at several points along their length and the rods embedded in concrete, hydrogen was evolved on the exposed steel surfaces. The surrounding concrete became porous with little bond to the exposed steel; the bond to intact galvanized surfaces remained unaffected.

Present indications are that, although the amount of gas liberated is sufficient to affect the bond, the galvanic cell between the galvanized surfaces and iron is rapidly polarized and hydrogen evolution ceases within 1 hr.

Thus, the adverse consequences of using galvanized reinforcement where alloys appear at the coating surface, having ungalvanized cut-ends, a damaged coating, or where it is used with ungalvanized steel binding wire, are clearly evident. Specifying a minimum thickness of coating does not necessarily obviate the problem since, as has been shown, even a coating of 1·00 oz./sq. ft. may have zinc-iron alloys extending to the surface.

Institution of Electrical Engineers, Electronics and Communications Section (in association with the Television Society, at the Institution of Electrical Engineers, Savoy Place, London, W.C.2)—International Television Conference.

Friday, June 1

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Mr. G. Bennett: "The Biology of the Astronaut".

Monday, June 4

University of London (at the London Hospital Medical College, Turner Street, London, E.1), at 5.15 p.m.—Prof. F. Halberg (University of Minnesota Medical School). "External and Internal Timing in Organisms".*

Monday, June 4—Thursday, June 7

British Electrical Power Convention (at The Dome, Brighton)—Fourteenth Annual Meeting. Theme—"The British Electrical Industry in the World Scene".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer in Sociology—The Registrar, The University, Leicester (June 2.)

Assistant Lecturer, an Experimental Officer (preferably graduate in physics or electrical engineering, or qualified in electronics) to take charge of the electronic equipment, and a Research Demonstrator (honours graduate in physics) in the Department of Physics—The Registrar, The University, Leicester (June 2).

Assistant Lecturer and a Tutorial Assistant in Sociology—The Registrar, The University, Leicester (June 2).

Lecturer in the Department of Veterinary Pathology, Royal (Dick) School of Veterinary Studies—The Secretary, The University, Edinburgh (June 4).

Assistant Lecturer (preferably with qualifications in social psychology) in Psychology—The Registrar, The University, Sheffield (June 5).

Lecturer (preferably with African field experience and interested in the geography of soils and the conservation of resources) in the Physical Geography of Intertropical Lands and in Survey and Cartography—The Secretary, The University, Edinburgh (June 5).

Senior Tutor (with a degree and preferably teaching experience) in the School of Mathematics, University of New South Wales—Agent-General for New South Wales, 56–57 Strand, London, W.C.2; and the Appointments Section, The University of New South Wales, Box 1, Post Office, Kensington, New South Wales, Australia (June 8).

Experimental Officer or Senior Experimental Officer in the Department of Mechanics of Fluids, for duties which will include the design and construction of electronic and optical apparatus for studying turbulence, aerodynamic noise and flows at very high speeds, including their interaction with magnetic fields—The Registrar, The University, Manchester 13 (June 9).

Lecturers (2) in the Department of Mathematics—The Secretary, The University, Edinburgh (June 9).

Scientific Officer (male, with a good honours degree), to engage in research on sugar beet breeding, with special reference to the exploitation of male sterility and polyploidy—The Secretary, Plant Breeding Institute, Trumpington, Cambridge (June 9).

Lecturers and Senior Lecturers in Philosophy at Monash University—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 or The Registrar, Monash University, P.O. Box 92, Clayton, Victoria, Australia (June 12).

Demonstrator (with, or about to obtain a good honours degree) in Physics—The Registrar, The University, Keele, Staffs (June 15).

Lecturer/Assistant Lecturer (preferably with experience in the field of magnetic resonance or microwave techniques) in the Department of Physics—The Registrar, The University, Keele, Staffs (June 15).

Lecturer in Geography at Fourah Bay College, University College of Sierra Leone—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (June 15).

Lecturer (with an honours degree in botany and postgraduate experience in taxonomic work) in the Department of Botany, University of Ife, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (June 19).

Lecturer or Assistant Lecturer in Physics at the Royal University of Malta—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (June 28).

Research Fellow in the Surface Physics Group, to join a team investigating mechanism of photoelectric emission—The Secretary and Registrar, The University, Southampton (June 30).

Chair of Physics in the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, July 7).

Assistant Lecturer in Agricultural Economics and Farm Management; and an Assistant Lecturer in Animal Husbandry—Clerk to the Governors, Essex Institute of Agriculture, Writtle, Chelmsford, Essex.

Lecturer or Demonstrator in Genetics, with special reference to cytology—Dr. C. B. Goodhart, Museum of Zoology, The University, Downing Street, Cambridge.

Master to teach Biology in VI form to A level; also General Science and/or Mathematics in Middle School—The Headmaster, King's School, Rochester, Kent.

Research Assistant in Organic Chemistry—The Secretary, Birkbeck College (University of London), Malet Street, London, W.C.1.

FUTURE OF PRIMARY AND HIGHER EDUCATION

THE report* of the independent committee under the chairmanship of Sir Charles Morris which, at the invitation of the National Union of Teachers, studied the expenditure needed for future educational development was published some two months before the Government announced its proposals for university development in the next quinquennium. As its title, *Investment for National Survival*, indicates, the report is, however, entirely pertinent to the discussion on Government policy inasmuch as, although primarily concerned with the supply of teachers to implement current proposals for educational reform, its main emphasis is on the cost of the necessary measures, which the Committee frankly recognizes will be expensive in manpower and womanpower as well as in finance. Nevertheless, its conclusions are framed in the belief that our national survival depends wholly on the manner in which we use our human resources. "If the country is to use its reserves of ability to the full it must create an educational system which provides adequate opportunities at all levels, which is staffed throughout by well-qualified teachers, and which offers both a broad, liberal education, and that degree of specialist training which will enable the individual to pursue his chosen career and contribute to the needs of industry, commerce or the professions." Furthermore, the Morris Committee recognizes that any proposals to this end must be executed quickly.

Now it is the contention of the Government in commending its proposals to Parliament that Britain's economy needs an increase—at least 35 per cent—in the supply of trained men and women coming from the universities but that the country's economy is such that it cannot afford to set aside just now the financial resources which those best qualified to judge believe are necessary to achieve the Government's target. In particular, the Government has postponed authorizing the salary changes that are regarded as essential to ensure an adequate supply of university teachers of the high quality required. The Government, in making its decisions, was fully aware that the whole pattern of higher education was already under review and did not attempt to anticipate the findings of the Robbins Committee. Neither, however, did it seek to ensure that those findings could be implemented without prejudice.

This report from the Morris Committee does not attempt to evaluate the different proposals for educational reform at present before the public but rather to consider the cost in money and teachers of implementing them and such other demands on education as will be exerted on the economy, by changes in population and by the demand for more education which is now making itself felt, and which while receiving less public attention have considerably increased the magnitude of the task. A valuable feature of the report is, in fact, the background paper in which J. Vaizey and S. Pratt estimate quantitatively the probable pattern of education now and up to 1970 and 1980, the demand for teachers, the supply of teachers and buildings and the probable costs. By 1970, they suggest, it is probable that more than three-fifths of our children will be taking courses of at least five years duration in their secondary schools and we may need 95,000 additional teachers to implement existing policies as well as about 10,0000 new teachers over the decade in higher education. To achieve 175,000 places in the universities and 40,000 elsewhere in the colleges of technology by 1970 would require 22,000 teachers, at about 1,700 a year to allow for wastage.

In all, they suggest we may need to find on average more than 30,000 teachers a year during the nineteen-sixties at an annual increment of £10–£20 million in the bill for education. Total capital investment in primary and secondary schools is put at £550 million with some £600 million for higher education by 1980, compared with the present rate of about £150 million a year. Unless the national income rises by at least 6 per cent a year the share of the national income to education is bound to rise, and, in the absence of new means of financial support, educational development must slow down or public expenditure rise. If, however, 4 per cent of the gross national product continues to be spent on education Mr. Vaizey and Mr. Pratt estimate it should be possible to double expenditure on primary education, with maximum classes of 20–25, to provide higher education for 600,000 and to double expenditure on secondary education, with education up to the age of 17–18 in classes of 20–25 and substantial margins for adult education.

The vital point they make is that it is extremely likely that a higher rate of educational expenditure now will help the national income to grow faster, and the faster the nation spends in the next decade, the easier it will ultimately be to provide a really lavish system. If higher education is expanded to yield an average gross flow of 30,000 teachers a year, all the reforms proposed can be achieved by 1970, but to sustain this rate of expansion the nation has both to expand higher education rapidly and to find the finance for an adequate educational system. This probably means an increase of £40–50 millions a year for at least twenty years and this is admittedly a heavy burden for the national exchequer and the local rates.

The Morris Committee believes that this investment should be made and the real issue with the Government is not so much on the magnitude of the investment as on its timing. Under the present plans it expects at least £1,300 million to be spent on public education in 1970, and changes in salaries and prices could well bring this to £1,500 million by that date—a figure which was anticipated by Sir David Eccles in the House of Commons fully two years ago. There is no minimizing the magnitude of this effort in terms either of manpower or expenditure, but in the full context of the economic situation the report maintains that it is essential for economic growth and the investment should be made now: to delay will not merely impair the nation's economic strength but will probably considerably increase the cost of achieving the objectives to which the Government is already committed if, indeed, it does not prejudice their attainment.

---

* *Investment for National Survival.* (The Report of an Independent Committee under the chairmanship of Sir Charles Morris on the Expenditure Needed for Future Educational Development.) Pp. vi+42. (London: National Union of Teachers, 1962.)

The economic argument on which the Government seeks to justify the proposals announced on March 14 appears, in fact, to be one of the most telling indictments of the policy of delay. It is a matter of timing as well as of values, and this is fully supported by the analysis which Mr. John Vaizey has recently published under the title *The Economics of Education* *. Reviewing primarily what has already been published on the economic aspects of education and the returns from education whether regarded as consumption of investment, he approaches the question what should be spend on education. Emphasizing that such expenditure should be studied in the context of the whole structure of public finance, he directs attention to factors affecting the expansion of education, such as the supply of teachers, over which Government spokesmen have passed too easily in the present discussion, and to the way in which that expansion has to be related to prior decisions about the rate of growth of the economy and about its general characteristics.

Fundamentally, Mr. Vaizey believes that decisions as to the role of education in the economy and the rate of expansion of education must rest not simply on a balanced view of the whole system of education but also on a reasoned discussion of its social purposes. We must be clear as to the ends to be served before sound decisions can be taken as to the means to be used. This is fundamental whether we are considering the development of secondary education or the expansion of the universities, but having willed the ends, we must also will the means.

This is the gravamen of the present charge against the Government over the expansion of the universities, but it is at least encouraging to note that in much of the evidence submitted to the Robbins Committee the purpose of particular sectors of education is fully considered. The memorandum submitted by the Manchester Local Association of University Teachers, for example, considers first the purpose and functions of universities, and it is from this that the Association proceeds to urge the vital necessity of institutions in which teaching and research proceed side by side. The Committee of Principals of Colleges of Advanced Technology likewise discusses the nature and specialized functions of higher educational institutions in general before outlining its views on the full development of colleges of advanced technology; and, if this is not done in the memorandum submitted by a group of Fabians *, this is because during discussions it was decided that it would be helpful if the Fabians, with their traditional interest in administration, concentrated their evidence on the structure of higher education rather than on broader issues of content.

In so far as the Government's decision to set aside the recommendations of the University Grants Committee have led to the expression of fresh doubts as to the adequacy of the existing administrative arrangements this Fabian pamphlet, *The Structure of Higher Education*, is of special interest at the present time. The effectiveness of the University Grants Committee has already been questioned in respect of university research, and in the recent debate in Parliament it was equally questioned in respect of research, when Mr. R. P. Hornby suggested that responsibility for the University Grants Committee should be transferred to the Minister for Science or the Minister of Education. There appears to be a considerable volume of opinion in favour of removing the responsibility from the Treasury; but opinion is divided as to whether it is preferable to give the Minister of Education responsibility in this way for all State educational services, including the colleges of technology as well as the universities or whether, on the contrary, the advantage lies in giving this responsibility to the Minister for Science, particularly in view of the research aspect and his responsibilities for the Research Councils.

Another possibility which has been suggested is the creation of a separate Ministry of Higher Education responsible for universities, colleges of technology and all centres of advanced training. Despite the solid advantage of the colleges of technology and universities being handled by one Minister, possibly assisted by a Technological Grants Committee, balancing the University Grants Committee and advised by the Advisory Council on Scientific Policy there are objections or difficulties to any of these proposals, though scarcely such as could not be overcome without serious duplication of effort, given real determination and goodwill. The Fabians lean to the second of the three proposals advocating the creation of a Higher Education Authority under a single department responsible for the whole field of higher education.

The proposed Authority would lay down lines of higher educational policy for Britain as a whole, and it would also co-ordinate the activities of the regional higher education authorities (of which about ten are visualized) which would be responsible for interpreting national policy in the light of local circumstances. The national authority, which would be appointed by the Minister of Education, would itself appoint the Regional Authorities and their chairman, and, since higher education is conceived as essentially a national rather than a local problem, would apportion financial grants from the Exchequer among the regional authorities. Nevertheless, the proposal is designed and intended to ensure the maximum interest and support from the local authorities.

---

* *The Economics of Education.* By John Vaizey. Pp. 165. (London: Faber and Faber, Ltd., 1962.) 21*s*. net.

* Fabian Tract No. 334: *The Structure of Higher Education.* (Socialism in the Sixties.) Pp. 20. (Fabian Society, 1961.) 2*s*. 6*d*.

The Fabian Group visualizes the real practical division in higher education lies between universities, colleges of advanced technology and teachers' training colleges on one hand and all other institutions on the other, and so far from wishing to discard the University Grants Committee it contemplates similar bodies for colleges of technology and for teachers' training colleges. None of the proposals, however, seems to contemplate the present situation in which the Government, having asked its responsible advisory body to formulate proposals to achieve a specific objective, has refused to will the means. No system can function effectively unless used with sense and insight, and whatever proposals may in the upshot come from the Robbins Committee, its report should at least bring a forcible reminder to the Government that if and when the nation's economic position is such that specific limits are necessarily set on the resources which can be allocated to particular ends, the appropriate institution should be advised before and not after it has formulated its plans. Failure to modify an objective when necessary at an early stage can result in serious waste as well as frustration, and it is difficult to clear the Government at this junction of the charge of causing waste as well as endangering the objectives it had set.

Meanwhile, it cannot be emphasized too strongly that even to maintain existing standards and serve the generally accepted ideas of universities as institutions in which teaching and research proceed side by side will involve the universities in expenditure which will go far to absorb the increased funds which the Government proposes to place at their disposal. Apart from the question of salary increments, there is the creation of more senior posts, such as readerships and professorships, and, at the other end, the provision of technicians and craftsmen and other ancillaries, lack of which is at present a serious handicap to research. The organization as well as the finance of research also present problems which will call for increased financial provision before we can wisely contemplate any expansion in student numbers with existing resources, and while it is possible that considerable economies should be obtainable in the cost of university education by modification in teaching methods and in buildings without necessarily lowering standards, it is scarcely reasonable to expect to achieve these with staffs that are already overstrained if not frustrated. Nor does it seem prudent to attempt more than exploratory measures when the whole structure of higher education and its balance is the subject of authoritative inquiry.

On almost every count therefore the Government policy appears to be ill-judged, and likely to prejudice rather than assist Britain's economic development. The-Robbins Committee can scarcely be expected to expedite the completion of its report by more than a month or two, and in the meantime the soundest course would be to ensure that the way is clear for whatever action may be recommended. Even from the strictly economic point of view, a first desideration in policy should be the removal of causes of waste and friction and, above all, of the frustration which could deny us the trained manpower and womanpower essential when the lines of expansion have been decided.

CANADIAN UNIVERSITY PROBLEMS

Canadian Universities Today

Symposium presented to the Royal Society of Canada in 1960. Edited by George Stanley and Guy Sylvestre. ("Studia Varia" Series, Vol. 6.) Pp. x + 97. (Toronto: University of Toronto Press, 1961. Published for the Royal Society of Canada.) 4 dollars.

THIS short book consists of papers contributed to the annual symposium of the Royal Society of Canada by eleven of the Society's Fellows. Four of the essays deal with the philosophy of higher education: the threat of over-professionalization; the search for an integrating theme in an age of abundant and narrow specialities; the preservation of the university as a centre of social criticism at a time when much of education is described as "adjustment to society". The remaining seven papers deal with severely practical problems facing Canadian universities: the population boom; the financial difficulty; the scientific lag in French–Canadian universities (three papers touch on this); and the need to join technology with pure science in a university setting.

Perhaps the most incisive chapter in the book is that on "The University and its Finances". The Vice-Principal of Queen's University informs us that "twenty-five years ago about two-fifths of a cent out of every dollar of gross national production . . . was devoted to higher education. To-day it is still only two-fifths of a cent, in fact slightly less, although the average material standard of living has more than doubled. In the same period student enrolment . . . has gone up three times, a rate of increase substantially greater than the growth in total population". By 1970 it is estimated that university enrolment will be double its present level; furthermore, costs per student are bound to rise substantially. Unless new money becomes available soon "a critical situation could be reached in a very few years. . . . Something would have to give way—it could be a considerable limitation on the number of students that may be admitted or it could be a serious deterioration in quality". Government, incidentally, provides 55 per cent of operating revenues at present; business and private benefactions account for only 4 per cent of income.

The editors assume that the conflict between science and humanism is "more apparent than real, more smoke than fire". The scientists among the contributors seem less certain. Dr. Steacie, president of the National Research Council, observes that "by refusing to take any interest in man's environment, there is no question that the humanists have surrendered their right to regard themselves as liberally educated, and have left a gap which must be filled". By comparison with the humanities, liberally supported by the Canada Council, "the sciences seem to be in something of the position of the labourer in the vineyard who toiled all day for one penny".

Due to their heavily classical tradition, the universities of French Canada (Laval, Montreal and Sherbrooke) have had great difficulty in adjusting to modern scientific culture, and have, so far, been unable to play their full part in scientific research. For the most part, we are assured, French and English-speaking Canadians get on well together in the national academic community. But there are indications in at least one paper of the familiar (and understandable) French-Canadian sense of injustice, which, in recent months, has led to a revival of Quebec 'nationalism' or 'separatism'.

Clearly, Canadian universities have their problems, some familiar enough to English academics, but some peculiar to themselves. BRIAN HEENEY

GEOGRAPHY AND ITS RECENT PAST

A Hundred Years of Geography

By T. W. Freeman. (The "Hundred Years" Series.) Pp. 335. (London: Gerald Duckworth and Co., Ltd., 1961.) 30*s*. net.

"THE history of geography is long and honourable," said Mr. J. N. L. Baker, in his presidential address to Section E (Geography) of the British Association in 1955, "No geographer need apologize for it or be ashamed of it". But the actual writing of the history of the subject during the past hundred years has awaited an author of Mr. Freeman's courage, breadth of thought, and fluency of writing. The story of the progress of any subject over the course of a century is difficult to relate—as other books in the "Hundred Years Series", of which this volume is the latest to appear, clearly show: but perhaps the achievement of geographers is especially hard to describe in a small compass if only because of their range of interest and of the many-sided development of geography, particularly during recent years.

Geographers will have abundant reasons to be grateful to Mr. Freeman, who is reader in economic geography in the University of Manchester and who has obviously greatly enjoyed his task of assessment, compression and selection. They will not always agree with his observations or accept all the innuendos: they may not invariably appreciate all the asides. But they will be glad to receive his guidance and can scarcely fail to profit from it, as they are led through the different branches of the subject as each has unfolded and developed over a century. Fortunately, the author is essentially catholic in his sympathies. On one hand he has a deep respect for our forbears, the nineteenth-century pioneers, who laid splendid foundations for the subject because of their concern for what Jean Gottmann has called "the broad and permanent problems of the world's partitioning": on the other hand he sees the future of geography lying increasingly in "closer study of a more restricted field, but by far more people than were available a generation ago".

Mr. Freeman looks first with understanding and appreciation on the subject as it existed in the mid-nineteenth century and then in the period immediately before the First World War. He evaluates the varied contributions that have come through exploration and through education, by the efforts of the numerous geographical societies which were founded and flourished during the nineteenth century, and from the developments in the academic world that owed so much, in their early days, to the encouragement of these societies. An attempt is made to consider these developments over a wide range of the subject, including physical, economic, social and political geography as well as cartography, while one chapter is devoted to what the author describes as "that most controversial of geographical topics, 'the regional approach'."

Quite often the reader may be tempted to query statements or interpretations: occasionally he may be surprised at omissions in the valuable and far-reaching bibliographical entries supplied in the notes and references that are—unfortunately and no doubt at the behest of the publisher—placed altogether at the end of the book. There is, for example, no specific reference to the boldest, if not perhaps the most carefully organized, of the attacks on the regional concept in geography. While there are useful biographical notes of about ninety geographers now deceased (some of them fortunate perhaps to find themselves in so select a company), some of the leading figures in British geography to-day qualify for no reference whatsoever. Consideration of the environmental determinism of Ratzel, Miss Semple, Ellsworth Huntington and others seems nowhere to be linked to the rebirth of some of these philosophical disputes during recent years. There might also be fuller references to some of geography's most significant growing-points to-day: the remarkable progress of historical geography, for example, or the growing concern of geographers for tropical studies, or developments in biogeography. Perhaps, though, there is point in Mr. Freeman's whole-hearted endorsement of H. R. Mill's contention that geography is "old even in the expression of ideas that we are apt to consider most modern": indeed he says as much when suggesting that "many ideas are produced, ignored, and revived fifty years or so later with good results".

Now, thanks to Mr. Freeman, geographers can look back over a hundred years of progress and change and thus appreciate better the status and prospects of their subject to-day. We can be grateful for the author's simple and forthright re-statement of some vital truths that must be recognized if the steady, balanced development of geography is to continue. It is good that the experts in particular fields should be reminded that "systematic and regional geography need not be thought of as rivals but rather as complementary, for each can fructify the other". Others can profitably be told that "too often regional study has been discredited by its superficiality and its readiness to generalize on inadequate premises; the macrogeographical picture must rest on the micro-geographical basis". Even the terse reminder that "neither statistics nor distribution maps in themselves are more than useful tools" has real relevance to-day. Geographers will therefore react to this book in different ways: some will be provoked, others may be tempted to question, but all should be encouraged. Readers who are not geographers will be given insight into both the history and the methods of a subject that is widely studied to-day but is still insufficiently understood or appreciated in many quarters.

In 1895, Mr. Freeman reminds us, the sixth International Geographical Congress was held in London and was hailed as "an opportunity, such as has never occurred before in this country . . . of demonstrating the importance of geography as a science of high precision and vast extent, rich in results of theoretical interest, and of practical value, which affords an unequalled discipline in education when rightly applied". Two-thirds of a century later geographers may have lost some of this evangelical fervour and would probably express their point of view a little more cautiously. But when the Congress comes again to Britain in 1964 geographers intend to seize their opportunity once more, and in their advance planning they will be fortified by the valuable reminder of the history of the recent past with which they are provided in this volume. R. W. STEEL

PHOTOGRAPHIC INTERPRETATION OF GEOLOGY

Photogeology

By Victor C. Miller, assisted by Calvin F. Miller. (International Series in the Earth Sciences.) Pp. vii+248. (New York: McGraw-Hill Book Company, Inc.; London: McGraw-Hill Publishing Company, Ltd., 1961.) 104*s.* 6*d.*

THIS book is an elementary introduction to the principles of photographic interpretation of geology. It is a lavish production and contains eighty halftone reproductions of stereopairs or single photographs which illustrate 'text-book' examples of different geological structures or geomorphological features, all from the United States or Canada. Each example is supported by a brief analysis of the features which can be interpreted from the photography and there are outline maps of the localities which can be used for practical exercises. The reproduction of the photography is excellent, and the plates can be examined through an ordinary lens stereoscope of small magnification without serious loss of quality. The book is specially bound with a ring back to allow the pages to lie flat for stereoscopic examination.

Although this book is worthy of serious study for the sake of these examples, the remaining text is of uneven quality. The chapters relating to the qualitative interpretation of geological features are elementary but sound. The author rightly emphasizes the importance of geomorphological analysis as the basis of any photo-geological interpretation.

The preliminary chapters which describe the elementary geometry of the aerial photograph, the principles of stereoscopy and the methods of measurement and plotting are the least satisfactory part of the book. It is reasonable to assume that a book of this sort should instruct the geologist how to transfer the results of his interpretation to a base map by simple graphical methods. Moreover, the ability of the geologist to use a parallax bar, or even a third-order photogrammetric plotter, greatly increases the scope of the work which can be done by allowing him to use quantitative techniques also. These subjects are referred to in the early chapters; but many of the essential elements are treated superficially and some are not mentioned at all. For example, the perspective geometry of a tilted photograph is only described for the representation of a plane surface; relief displacement is only considered for the truly vertical aerial photograph. The combined effects of tilt and relief displacement are not described although these effects occur in practically every aerial photograph which the geologist will examine. The method of plotting principal point base-lines which is described depends on the assumption that the image of each principal point can be transferred from one photograph to the next by inspection. There is no mention of the methods which have to be used in the common case of these points lying in areas of comparatively featureless terrain. The section describing stereoscopic parallax is most unsatisfactory. The parallax equation, which is introduced without proof, is incorrect and there is no explanation of the kinds of errors which will be experienced in determining height differences from simple parallax measurements on tilted photographs. The radial line assumption is glossed over in no more than a sentence and the use of anharmonic ratios as an alternative method of transferring detail from the photograph to the base map is not mentioned. A variety of second order and third order photogrammetric instruments are splendidly illustrated, but the reader is left in some doubt about how these instruments can be used or their relative merits for compilation of photogeological maps.

D. H. MALING

BIOLOGY OF PARASITES

Parasitology

The Biology of Animal Parasites. By Prof. Elmer R. Noble and Dr. Glenn A. Noble. Pp. 767. (London: Henry Kimpton, 1961.) 82*s* 6*d.*

THIS book does not, so its authors say in their preface, attempt to duplicate the contents of a text-book of clinical parasitology. It attempts, in fact, the difficult task of summarizing our knowledge of the biology, rather than other aspects, of parasites of all kinds. One of the aims of its authors is the admirable one of offering parasitology to the undergraduate as a major field of study, and the undergraduate thought of is the one who has already completed at least one year of introductory biology or zoology and yet is surprisingly called by the authors "advanced". The research worker, however, is also catered for. He is warned that he will not find in the book exhaustive consideration of his own field of work, but he will, the authors hope, find the various fields of general animal parasitology summarized and brought up to date.

This combined aim of trying to cater, in one volume, for the needs of the young undergraduate and the research worker is bound to be difficult; some will doubtless feel that it is impossible. So much will depend on what the young student has already been taught, and on how it has been taught and on whether the undergraduate can advance beyond the facts he has already. There is so much detail in the text of the book, and also in its illustrations, that some students may be intimidated by the complexity so rightly recorded here. On the other hand, there will, one hopes, be other students who will welcome this complexity and will find in it a challenge which will lead them on to serious, independent work and later to discovery.

For senior workers the book contains much that will be valuable. Its first eight chapters deal with the biology of parasitic members of the main taxonomic groups of animals, including an all too brief chapter on the parasitic mesozoans, coelenterates and other groups which standard text-books, dealing only with species of économic importance, often leave out. In Chapter 9 the physiology and biochemistry of the parasite are discussed. In Chapters 10–14 we learn about their ecology, and in Chapter 15 about their evolution. At the end of each chapter there is a useful brief bibliography. Well printed and handy in size, the book gives us many illustrations, most of which are good, while some are unique, and others could have been improved. Most of them are borrowed from other books or from research papers.

But the main value of the book is the fact that it brings together our knowledge, not so much about the systematics, structure and great economic importance of the parasite, but about its biology and about the basis of the parasitic mode of life. It was high time that such a book was prepared. If it contains here and there some statements which can be criticized, it should be remembered, not only that it is easy to criticize and very difficult to write a book of this kind, but also that nobody yet has written a book that does not, in some respect, arouse controversy. It is good, in fact, that it should be so, for the senior reader can, from his own experience, correct what he does not accept; and the student can refer to him whatever may puzzle him.

So far as I am concerned, I am glad to have this book. It breaks new ground and illustrates the gratifying fact that parasitology, which for so long has been one of the 'Cinderellas' of biology, is nowadays getting the attention it has always deserved. The parasite, as will be realized by the reader of the early pages of this book, may be, perhaps, indefinable, but it does take us, the more deeply we study it, far beyond biology and straight to the very roots of our general philosophies. G. Lapage

CUP FUNGI

British Cup Fungi and Their Allies

An Introduction to the *Ascomycetes*. By R. W. G. Dennis. Pp. xxiv+280+40 plates. (London: The Ray Society, 1960. Sold by Bernard Quaritch, Ltd., 11 Grafton Street, London, W.1.) 80*s*.

No more generous publication has been offered the student of British ascomycetes. By a handy, well-printed and copiously illustrated volume this flora of myriad fungi from *Eurotium* to *Morchella* has been reopened. "Most of the genera said to occur in Britain are illustrated." About 1,000 species in 450 genera are described. For some 180 species taxonomic points are explained in twenty figures of line-drawings. Forty colour plates depict fructifications and spores of nearly 500 species. Most, if not all, descriptions and illustrations in the tradition of Kew mycology are original; they reflect the patience and skill which has been devoted over many years to this artistic product.

The keys to the families and genera are concise and appear to be satisfactory; but in the case of large genera, for which numerous species are described, the absence of specific keys is annoying. The major key to the orders is strange. It is not, as stated, a key to the larger ascomycetes but one to all the ascomycetes in minutest detail, such as will baffle the beginner. The name 'cup-fungi' has been retained throughout the book, and pyrenomycetes are mixed up with discomycetes inasmuch as these two standard groups are, without explanation, completely passed over. Plectascales are associated with Tuberales, and *Nectria* becomes a cup-fungus. A great opportunity has been missed both to help the beginner and to explain the new alternative. The book is stern, but it will make its way overseas because most genera are cosmopolitan and a comparable introduction is scarcely available. Lexicographers will find hidden in the text new combinations.

In all this advantage there is a vexatious omission. Has the author, so expert in this group, turned his back on science? "Taxonomy . . . not a science but an art" (p. xvii). Many of these fungi have been objects of research. To have left this knowledge out merely pales the introduction but, names having been changed and the clue to research residing in the twisted thread of synonymy, to have left this out is ungracious. Where is *Ophiobolus graminis*, and is it rightly named? Where is *Peziza aurantia*, the standard cup-fungus of modern botanical teaching? Without explanation it becomes *Aleuria aurantia* (not ascertainable from the key on p. 1). *Aleuria* is "one of a residual assemblage of genera defined largely by negative characters". *Peziza* becoming *Aleuria*, Aleurieae become Pezizeae, and vice versa, as one might swop *Amanita* and *Lepiota*. The student is referred to a monograph where this *Peziza* is called *Aleuria* (cum *Galactinia*), and the author toys in small print with the popular name "Orange peel Peziza". Scientists try to respect taxonomy. When, artfully or artlessly, it gets in this mess, minds begin to work on a new and scientific taxonomy. The stirrings are abroad, and this book, with its great appeal, will promote them. E. J. H. Corner

HYDRA

The Biology of Hydra and of some other Coelenterates

1961. Edited by Howard M. Lenhoff and W. Farnsworth Loomis. Pp. xv+457. (Coral Gables, Florida: University of Miami Press, 1961.) 4.50 dollars.

This book consists of twenty-three papers delivered by North American workers at a symposium in Miami during March 1961, with thirteen exclusively on *Hydra*, and six more general in nature. Topics covered include: electron microscopy, nematocysts and their toxins, nutrition, growth and differentiation, regeneration, colony formation, and sexual differentiation.

Here is an unusually good example of a single animal treated by widely varying techniques, and it will prove stimulating to alert readers who, if prepared to think for themselves, will achieve some of the "interdisciplinary synthesis" aimed at by the editors. This is helped greatly by the inclusion of the discussions which followed the papers and the additional one on the nervous system of *Hydra*.

Its main value, however, even if rather ephemeral, is for research workers, and for them the aggregation of such diverse material, much of it previously unpublished, under a single cover must be applauded. Most chapters are followed by an almost invariably up-to-date bibliography. Unfortunately, comment on the systematics of *Hydra* is omitted yet frequent discrepancy apparently within species is described.

This is a well-produced volume. Its tables, diagrams and plates are variable but generally adequate and sometimes good; many of the electron micrographs are excellent though occasionally spoilt by the absence, or only obscure insertion, of a magnification indicator.

It is more than two centuries since Trembley's *Memoire* appeared and yet the problems of nematocyst discharge, nerve net and sexual differentiation in the coelenterates still remain unsolved. Mary Campion

Audubon and his Journals

Edited by Maria R. Audubon. With zoological and other notes by Elliott Coues. Vol. 1: Pp. xiv + 532. Vol. 2: Pp. viii + 554. (New York: Dover Publications, Inc.; London: Constable and Co., Ltd., 1960.) 2 dollars each volume.

THESE two 'Dover books' (in stiff paper covers but suitable for rebinding in cloth) represent an unabridged and unaltered republication of the work originally issued in 1897. It consists of a biography (some 70 pp.) of John James Laforest Audubon by his granddaughter, supplemented by certain of Audubon's own journals and a number of short 'episodes' from his publications. The whole provides a picture of the personality and career of a man whose name has become in the United States—in the titles of national and local societies—synonymous with the conservation of wildlife, notably birds. Audubon was born in Louisiana, probably about 1780, the son of a French admiral and his Spanish Creole wife. He was brought up mainly in France but returned to North America as a young man; there he settled, married, suffered many vicissitudes, and became famous as a naturalist and artist, dying in 1851.

Of special interest from the Old World point of view are the European journals, 1826–29, covering the period when Audubon worked in London and elsewhere on the publication of parts of his illustrated folio *The Birds of America*, now a rarity. He naturally met many contemporary figures and, while spending part of the time in Edinburgh, he had William MacGillivray as a collaborator on the scientific side. The Labrador journal, 1833, and the Missouri River journals, 1843, give a good idea of travel, conditions, and wildlife in those parts more than a century ago. The 'episodes' deal with many different matters; in so far as they are dated, they refer to the period 1808–33 and help to fill gaps where journals have not survived.

LANDSBOROUGH THOMSON

The Mathematical Theory of Linear Systems

By Prof. B. M. Brown. (Automation and Control Engineering Series.) Pp. xv + 267. (London: Chapman and Hall, Ltd., 1961.) 50s. net.

THE mathematics underlying the many analytic methods now used in modern control engineering is of necessity omitted from most of the text-books on the subject at present available, and has also not been obtainable hitherto in one book. This gap is filled by the present volume, which is the second of a series entitled *Automation and Control Engineering*.

The work presents clearly yet comprehensively the basic mathematics of linear systems, and in particular of feedback control systems, developed in a logical manner from a starting point no more complex than the basic concepts of differentiation and integration.

The first five chapters are devoted to introduction and to the solution of linear equations by operational, Laplace, and Fourier methods. In particular, the author stresses the value of the bilateral Laplace transform, and compares the applicability of each method in various situations. The mathematics of conventional linear systems is completed by chapters on step and impulse functions, system analysis, feedback and stability. Two chapters are then devoted to statistical methods and the optimization problem, and the final four chapters to finite difference methods and their application to sampled data systems.

The text includes many worked examples of the methods described, and also references, and concludes with twelve substantial appendixes of topics too specialized to be included in the main development. The clear and logical treatment followed throughout is particularly attractive, and renders this book suitable as a teaching text.

E. M. DEELEY

The Veterinary Annual, 1961

Edited by W. A. Pool. Pp. xxiv + 406 + 34 plates. (Bristol: John Wright and Sons, Ltd., 1961.) 42s.

WITH this, its third edition, the *Veterinary Annual* is now firmly established, and has achieved its own distinguished place in veterinary literature. A noteworthy feature is its wide appeal; designed primarily to help practitioners to keep in touch with recent work it is to-day quite widely used by research workers, advisory officers and teachers.

Following what has become its established pattern this year's volume contains, in addition to contributed short reviews on many subjects, a number of special articles. There are eight of these dealing with veterinary medicine in West Germany; in Switzerland; Army Veterinary Services; the ecological approach to veterinary medicine in the United States; parasitological complications of intensive sheep grazing; hides, skins and leather; the physiology of the udder; animal trypanosomiases in Africa; and the unusual but topical subject of retirement from the Colonial Service. These have all been written by prominent workers with close contact with the various subjects and they add greatly to the interest of the book.

A feature is the provision of a list of selected references to each topic, quite a number of them from foreign journals. The value of the lists would be improved if each item from a foreign publication gave information on (*a*) the language in which the original is written, and (*b*) any abstract in English which may be available.

Concise History of Logic

By Heinrich Scholz. Pp. xv + 140. (New York: Philosophical Library, 1961.) 3.75 dollars.

THIS slender manual is a translation from the author's *Abriss de Geschichte der Logik* (second, unchanged edition), which appeared in 1959. Valuable as it is in many ways, it is a pity that steps were not taken to bring the sources more nearly up to date. Bochénski's *Formale Logik* had appeared in German in 1956, and became available in English last year. These events do not detract from the importance of the late Prof. Scholz's masterly sketch so far as it goes, but with these recent developments in view, one can scarcely expect a wide circle of readers in Britain.

The amount of material incorporated is astonishing, and this alone, with the copious notes and references, will assure a ready welcome. A good feature is the general treatment of 'types' of logic (rather than by any other classification), for this brings out the basic distinction between classical formal logic and modern formal logic. Thus, the greatness of Aristotle is seen in correct proportion, not as an obsession, and the unique position of Leibniz is well displayed.

Unluckily, however, the very personal style of the German original has made the translator's task exceptionally difficult, and some of the passages are far from idiomatic English. There are also too many tiresome colloquialisms.

The author's erudition is impressive: this alone commends the book to students who are willing to grapple with some decidedly difficult reading.

F. I. G. RAWLINS

RADIOCHEMICAL RESEARCH LABORATORIES AND THE LAW

By DR. HUGH D. EVANS

Health Physicist and Lecturer in Radiation Hazards,
Imperial College of Science and Technology, London

THE legal requirements which have to be fulfilled by persons or organizations using radioactive materials are not clearly understood by the vast majority of workers in this field. There is, in fact, very little Statute Law, though this state will not continue for much longer; what is so often forgotten is that there is considerable scope for Common Law actions in Great Britain.

The discharge of noxious wastes, which can include radioactive material, has long been controlled by legislation such as the Salmon and Freshwater Fisheries Act, 1923, the Public Health Act, 1936, the Public Health (Drainage of Trade Premises) Act, 1937, the Water Act, 1945, and the Rivers (Prevention of Pollution) Act, 1951; but much more specific control will, in the near future, be exercised by the Radioactive Substances Act, 1960.

The handling of radioactive materials in factories is partly covered by the Factories (Luminising) Special Regulations, 1947, and, since February 1, 1962, by the Ionising Radiations (Sealed Sources) Regulations, 1961. The terms of reference of the latter will be extended by a new Act, in the relatively near future, to include unsealed radioactive materials[1].

Apart from these Factories Acts, the only other relevant legislation affecting laboratories outside the United Kingdom Atomic Energy Authority is the Nuclear Installations (Licensing and Insurance) Act, 1959, which is concerned primarily with criticality aspects and the provision of adequate insurance cover in the event of a nuclear accident.

Let us now look at the situation from the point of view of research laboratories. In the first place, since they are exempt from the provisions of any of the Factories Acts, the Factories (Luminising) Special Regulations, 1947, the Ionising Radiations (Sealed Sources) Regulations, 1961, and the companion Act covering unsealed radioactive materials[1] do not apply. This exemption applies to research laboratories in universities, Government establishments, research associations and even in factories; but in the case of the last-named, they must be used exclusively for research and not, for example, combined with a process control laboratory.

Clearly, the Nuclear Installations (Licensing and Insurance) Act, 1959, applies to any organization operating a reactor or processing nuclear fuel, and a few research laboratories, both in industry and the universities, will therefore be affected.

The Radioactive Substances Act, 1960, will control the discharge of radioactive waste from all types of establishments, including research laboratories. It may not be evident at first sight, however, that its powers are much wider, since it requires users of radioactive materials to register with the Ministry of Housing and Local Government; if practice in an organization is found to be unsatisfactory, it will be possible to stop work by withdrawal of the licence.

Apart from this, it would appear that research laboratories have considerable scope for malpractice in the use of radioactive materials, and it is to be regretted that in many, due largely to ignorance of the necessary precautions, work is carried out under conditions which, if not an immediate danger to health, are potentially hazardous. What is so often forgotten is that such practices open the door to justifiable or spurious claims under Common Law. Many injuries or diseases (for example, leukæmia and cataract) which occur in a normal population, have increased incidence in persons exposed to radiation and it is impossible to differentiate between those which are or are not radiation-induced. If working conditions have not been of the highest standard, a legal claim has a fairly high chance of success; but if the employer can show that the precautions taken were adequate (often a debatable point), that all reasonable means of measuring personal dose were provided and that the employee did not at any time receive doses of radiation in excess of those recommended by the International Commission on Radiological Protection[2], then it is unlikely that the Court will uphold the claim. It must be remembered that there is, as yet, very little Case Law on this subject, so test actions are probable and these may well be taken to higher courts. Even for the winner of such actions, costs are likely to be high and a settlement out of court may be preferred. In a recent case (March 1962) it was alleged that a man had contracted leukæmia and cataract as a result of working at Windscale; the United Kingdom Atomic Energy Authority settled out of court for £4,500, without admitting liability.

Clearly, a reputable research organization must institute the safety measures appropriate to its work, not only for the well-being of its staff, but also to protect itself against Common Law actions. This is often accomplished by means of a Code of Practice, which does not have the force of law, outside the establishment, but can be made obligatory within.

One of the earliest Codes in the field of radiation and radioactivity was issued by the Ministry of Health in 1957 [3], principally for the benefit of hospitals, who were at that time probably the major users of radioactive materials outside the United Kingdom Atomic Energy Authority; this Code is at present under revision. Other Codes have been issued by Imperial Chemical Industries, Ltd.[4], the International Atomic Energy Agency[5] and the International Labour Office[6].

The universities have also produced similar documents. The first advisory booklet was published by the University of Cambridge in 1957 [7] and this was followed, also in 1957, by the Code of Practice of the Imperial College of Science and Technology, London[8]. The latter was the first university Code to lay down specific internal regulations and has been widely used in universities and in industry, as a basis for their own regulations; a fourth edition is at present in preparation.

In 1958 the Committee of Vice-Chancellors and Principals of the Universities discussed the whole problem, especially with regard to the possible repercussions of forthcoming legislation on university research. As a result, a sub-committee was formed, with the task of preparing a Code of Practice designed for university conditions; this was published in February 1961[9] and provides a basis for introducing a uniformly high standard of radiological protection in the universities.

Besides these Codes, there is yet another in preparation by the Ministry of Labour, which will be the companion of the Ionising Radiations (Sealed Sources) Regulations, 1961, and the Act which will derive from the Unsealed Radioactive Substances Regulations[1]. This will cover research laboratories in Government establishments, hospitals, research organizations and the universities, but unlike the two Factories Acts, it will not have the force of law. Other Codes in Great Britain will almost certainly be revised to make them compatible with it, although many will continue to be more restrictive.

Clearly, no research organization can afford to be complacent about precautions where radioactive materials are concerned. Though not rigidly bound by Statute Law, the implications of Common Law actions are far too serious to be neglected. There is, however, as has been shown in this article, a wide range of information available, and it is to be hoped that greater advantage will be taken of it.

SAFETY IN LABORATORIES

By PROF. R. A. MORTON, F.R.S., and DR. J. GLOVER

University of Liverpool

As universities and similar institutions grow larger, and the work done in laboratories and workshops becomes more complicated, there is greater need to maintain and strengthen safety precautions. Some years ago the University of Liverpool appointed a retired fire officer to inspect and maintain portable fire-fighting appliances throughout the university and to see that they were placed in the best positions. Later, many hand-operated fire-alarm bells were hung in carefully chosen places, and additional ways of quitting buildings in an emergency were agreed on and sign-posted. Members of staff, technicians and senior students were instructed as to their duties in case of fire.

The next step was to appoint a member of the staff of the Department of Physics to act as 'radiation officer', responsible for the safety of persons using radiation equipment and radioactive isotopes in university laboratories.

Important as the fire and radiation hazards undoubtedly are, there are many other risks. Safe working requires foresight, organization and discipline, all of which can be sensed by visitors to the more 'safety conscious' industrial premises. The many types of building which make up a university present very different hazards; thus, in a chemistry laboratory cuts from glass, splashes of chemicals in the eye and organic solvent fires are ever-present dangers, while mechanical, electrical and radiation hazards are more frequent in physics and engineering laboratories.

At Liverpool, the Fabric Committee, after conducting investigations, and making visits, recommended the appointment of a full-time safety officer with industrial experience. This was agreed to and the post has been filled. It supplements the provision already made through having a fire officer and a member of staff responsible for protection against harmful radiations.

During the Lent Term this year courses of lectures and demonstrations have been given on safety in laboratories with co-operation from the Department of Extra-Mural Studies. The main course was held on Wednesday afternoons during ordinary working hours and was attended by representatives of the teaching staff, research students, senior technicians, tradesmen and porters. The audience numbered about a hundred. The course was planned and organized for the University by Dr. L. J. Burrage (laboratory administrator, Research Department, Imperial Chemical Industries, Widnes), who has specialized in this field and was able to call on leading experts to deal with particular topics.

The course was introduced by H.M. chief inspector of factories (Mr. T. W. McCullough), who displayed statistics on the nature and causes of industrial accidents. Of the annual total number (190,000) of accidents recorded (involving three days or more lost time) some 26 per cent occurred in handling goods and another 16 per cent involved power machinery. Untidiness, accounting for 8 per cent, emphasized the importance of 'good housekeeping'. Mr. McCullough also stressed the need for care in designing machinery and suitable guards to ensure safe working.

With the latter in mind, Dr. Burrage gave his first lecture on "Safety Equipment and its Design", and traced the development of a range of safety measures appropriate for the chemical laboratory. In his second lecture he discussed in more detail various types of guards for laboratory equipment and machinery. Protective clothing, eye shields and goggles were exhibited and illustrated by lantern slides. Many of the devices described were the outcome of years of experience in dealing with laboratory and workshop hazards. Particular stress was laid on protection at the actual source of danger so as to inculcate in staff and students habitual attention to safety in conducting chemical and physical experiments. Advice was given on the proper screening of apparatus which in use was attended by risk. Much attention had been paid to safe ways of carrying dangerous chemicals from one place to another. It was important that each item of safety equipment should be correctly sited and given regular inspection and maintenance.

The third session was devoted to 'housekeeping'. Dr. Burrage laid stress on the fact that true tidiness helped to generate the right attitude towards safety among staff, technicians and students. This led to the conclusion that many accidents can be prevented by adopting some simple but important measures: (1) the benches and floors should be cleared of flasks and apparatus not actually in use; this would reduce breakages as well as risks; (2) reagent bottles should be properly labelled and kept in allotted places with labels to the front; (3) large bottles, winchesters or dangerous chemicals should not be placed on shelves above eye-level; (4) all laboratory workers should be taught to assemble apparatus correctly and neatly and to avoid trailing electricity leads or unnecessary lengths of rubber or plastic tubing.

Valuable suggestions were made on where to place and how to move gas cylinders and fire-fighting equipment. The disposal of waste products always merits strict adherence to a well-considered plan.

Dr. Burrage gave a fourth lecture on the "Correct Handling and Use of Glass". He made many points on care and attention in handling and cleaning glassware and glass tubing so as to reduce the number of accidents. Of the total injuries reported in the chemical laboratories of Imperial Chemical Industries some 30 per cent involve glass cuts. Vacuum and pressure lines ought to be correctly fitted and erected and protective screens should be in use. The lecture was well illustrated with lantern slides.

On the fifth and sixth occasions the audience was offered the choice between lectures on the hazards met in science or engineering laboratories.

Good and bad ways of handling quite ordinary, as well as dangerous, chemicals were described in the science lectures. The proper use, care and maintenance of fume-cupboards was discussed fully. The dangers of explosion which are associated with ammoniacal silvering solutions, or isopropyl ether left to stand, or through contact of strong oxidizing agents with organic matter, were pointed out and the appropriate precautions were detailed. When mercury is spilt it can run out of sight and be forgotten. In a poorly ventilated space it can give rise to toxic amounts of mercury vapour. Misuse of a mercury-diffusion pump without a liquid nitrogen trap is also hazardous. Awareness of these risks is the main thing; they can then easily be eliminated by responsible persons. Strict precautions to be taken in dealing with specially dangerous chemicals, for example, fluorine, chlorine and bromine, strong acids and gases such as hydrocyanic acid and acetylene were also discussed.

The engineering lectures were given by Mr. R. K. Mawson (deputy senior engineering inspector of factories, Ministry of Labour), who discussed the "Guarding and Safe Operation of Various Types of Mechanical Equipment", and by Mr. S. J. Emerson (senior electrical inspector of factories, Ministry of Labour), who dealt with "Electrical Risks and their Elimination". In the seventh session "Personal Protective Equipment" was discussed by Dr. Burrage more fully and a number of specimen articles were on show and their use was demonstrated.

In giving the eighth lecture, Mr. T. E. Hall (principal, Liverpool College of Building) suggested that a more positive attitude should be taken to safety in laboratories and similar buildings by training people in 'safe working' rather than in 'accident prevention'. Simple features of the design of buildings were often important factors in safety, for example, the way in which a door opens into a room and even the exact position of the handle. The treatment given to floors should minimize the risk of slipping; and uneven flights of stairs should be eliminated. A pleasant room with a good layout of equipment lessens accidents by reducing fatigue.

Finally, Mr. Hall emphasized that in addition to correct siting and maintenance of equipment it was important to give full instruction, particularly to the younger workers, on how to use machines and instruments. In the remaining sessions, Dr. Burrage discussed fire-fighting and first-aid equipment. All this he thought should be kept off the floor in panels, preferably near the door to make it strike the eye and be accessible for use, or inspection. Again, fire-alarms should be prominent and audible in every part of the building when people are working. The respective merits of the different types of fire-fighting equipment were explained and advice was given regarding the use of extinguishers and the number of pieces required in various types of premises. The most frequent laboratory fire hazards and the steps which must be taken to avoid them were then described. Dr. Burrage pointed out that everybody who works in the laboratory or other building should be instructed in the use of the equipment, so that the most appropriate piece is chosen in an emergency.

This also applies to first aid, where training of staff is invaluable. In general no one should be allowed to work in a laboratory alone, particularly at night; a second person can usually render first aid and can summon help quickly in the event of a serious accident. All workers should make themselves familiar with the nearest first-aid supplies and especially with the location of wash solutions specially provided for accidental splashes on the skin or eyes. They can be assisted in this by sign-posting in green, following the convention that this colour is associated with safety. Dr. Burrage also recommended that when showers are provided they should give a vigorous spray of water from the side rather than from overhead. He then discussed the treatment of some chemical burns and the action to be taken when workers have been accidentally exposed to doses of toxic substances.

The lecture course was concluded with an excellent film on "Safety in the Laboratory", shown by courtesy of Imperial Chemical Industries (General Chemicals), Ltd. The film brought out very successfully many of the points covered in the previous lectures and emphasized them in a forceful and gripping way.

Dr. Burrage and the other lecturers are to be congratulated on giving a most useful course, which was very well attended and broke new ground in the University. By striving for safety in its own premises a university community may incidentally be providing a desirable educational service to its students, who will in due course bear responsibility elsewhere.

ELECTRICAL MACHINES OF THE FUTURE

Substance of a Friday Evening Discourse at the Royal Institution

By Dr. E. R. LAITHWAITE
Electrical Engineering Laboratories, Manchester

THE subject 'electrical machines' may cover a great variety of devices from turbo-alternators and induction motors to computing machines and particle accelerators. Here, however, I am mainly concerned with solid objects which move, in short, with what were included in the heading 'electrical machines' perhaps fifty years ago. Such machines are mainly used for converting electrical power into mechanical power, or vice versa, and the object of the designing engineer is always to produce a machine which gives the maximum return for the minimum outlay of money. For example, he may be concerned with getting the highest efficiency out of his machine, that is to say, wasting the minimum of power in the conversion process. On the other hand, he may not care about this aspect too much, provided he can get the maximum amount of power from a given size of machine. In some cases, he may forgo a great deal of either of these aspects, provided he makes a machine which is guaranteed to operate year in, year out, without attention of any kind.

In design problems the engineer is generally faced with so many alternatives that it becomes almost impossible to write down equations which represent the problem, and it is quite surprising to what extent design is still an art as much as a science. If a bunch of keys be dropped on to a table it seems scarcely possible to calculate the final rest position of each key, yet to do it experimentally is a simple matter and there is one and only one answer, which means that a unique theoretical solution should be possible. Very often, in complex problems, we make use of models, and the electrical engineer often makes a mechanical model of a problem to help him appreciate the implications better. There is a real danger in pursuing such techniques too far, however, for often one can pin such faith in the model as to believe that it represents the original problem in every way, whereas in fact the basic concept of the original problem may not be understandable.

Such may be the case with our commonest form of electric motor—the induction motor. A simple form of induction motor consists of an iron ring carrying coils which are supplied with polyphase alternating current. When switched on, nothing which is detectable chemically occurs in the centre of the ring. The space is still filled with air. But something curious has happened, for if an aluminium or copper ball be placed inside the ring it will be rotated even though it makes no physical contact with the ring at all. The forces are applied across space and are of the same nature as those of gravity. The honest answer to the question of how it works is: "We do not know".

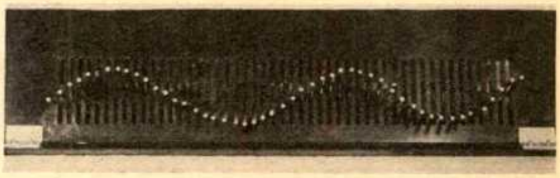

Fig. 1. Mechanical model illustrating travelling waves

What we can do, however, is make a mechanical model which together with other analogues helps us to believe that we understand, in fact so much so that we can exploit the principles of induction very well indeed and make very useful motors.

The first analogue we use is that of the rotating magnetic field. If a pair of horseshoe magnets be mounted on a wheel with their poles facing a copper disk, so that they can be rotated around the face of the disk, they are found to try to drag the disk around with them. We say that the moving magnetic field cuts the conductor and induces a voltage into it, which causes a current to flow. The current in turn produces a field which reacts with the original field to produce the torque. In saying this we have really 'explained' very little; but what we have done is to suggest that whenever a moving magnetic field is produced it is capable of exerting a force on a piece of conductor, no matter how we produce that field. Now, in the case of the ring and the ball we produced our moving magnetic field by means of stationary coils.

To try to understand how this is done we may make a mechanical model such as that shown in Fig. 1. Each of the metal rods is capable of being moved vertically, but not horizontally, since it is confined within a vertical slot. If we arrange to move the rods up and down rhythmically in a certain order we can produce the effect of a travelling wave, like a ripple in water. If, however, we seriously consider just what does move sideways we are forced to the conclusion that it is nothing more than an 'idea' in our heads. The most interesting demonstration, however, consists of placing a ball on the set of rods when the wave is being produced. The ball is moved along horizontally and the 'idea' has become a reality. In the case of the induction motor the rods are represented by the coils on the ring, each of which produces a magnetic field which goes up and down in value; but the coils are so phased with respect to each other as to produce the effect of a travelling magnetic field. It is when a conducting object is placed in this field that the idea of movement is turned to reality by a process which we do not understand.

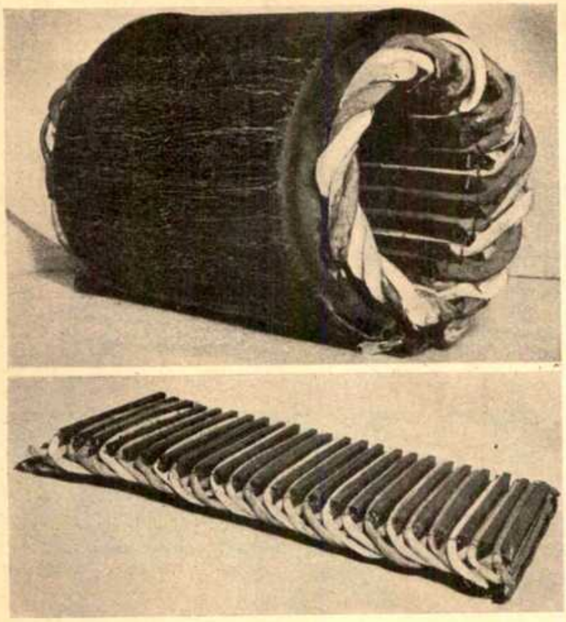

Fig. 2. Top, rubber model of the stator of a conventional induction motor; bottom, model split and opened out flat

Most of our electric motors have rotating fields and produce rotary motion of a shaft. There is no reason, however, why the motion cannot be reproduced in a straight line. Fig. 2 (top) shows a rubber model of the stator of a conventional induction motor. This model can be split along one side and opened out as shown in Fig. 2 (bottom). An actual motor constructed in this form is shown in Fig. 3, and it is capable of accelerating conducting objects in a straight line.

When one considers the number of industrial processes where motion in a straight line is used, the first natural question to ask is: "Why is the linear motor not being used ?" The final answer to this question is that induction motors are only good machines if their surface speed is high enough, and unless the speed exceeds 20 ft./sec. the machine is rarely good enough to be acceptable economically.

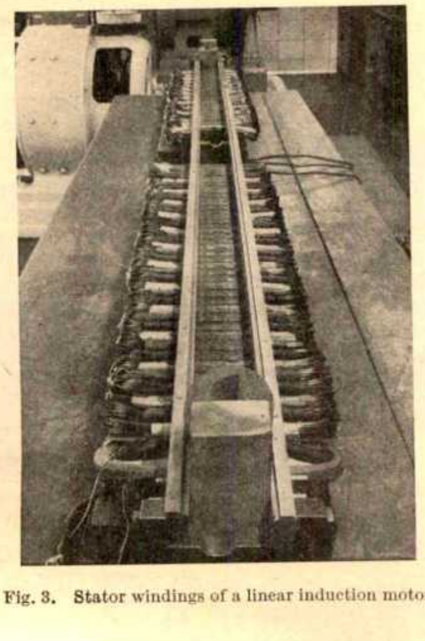

Fig. 3. Stator windings of a linear induction motor

One possible application where a high speed is required is that of propelling a shuttle across a weaving loom. One of the main problems here is to obtain reversal of motion. Normally, it is necessary to interchange two phases of the supply to an induction motor in order to reverse the direction of motion; but such an operation would demand switching of highly inductive circuits perhaps 200 times/min. By suitable design of linear motor, however, all switching can be eliminated, and the motor made to oscillate by itself. The principle of self-oscillation is shown in Fig. 4. Two linear motors are placed back-to-back so as to accelerate the 'rotor' or shuttle towards the centre. At first sight it appears that a rotor will oscillate in the manner of a pendulum under gravity, finally coming to rest in the centre because of friction and other imperfections. This, however, need not be so, since the force on the rotor can be made to vary with speed in the manner shown here. A rotor starting at A is accelerated towards the centre by forces Oa to p arriving at velocity v, say, as it crosses the centre. On entering the reversed field it is effectively moving against the field and therefore at speed $-v$ and is brought to rest at B by forces q to a. Now these forces are less than the accelerating forces and in the absence of friction $x_2 > x_1$. Each succeeding traverse will get bigger until the peak force is exceeded and the rotor approaches the field speed at the centre. Beyond this no further increase can occur.

One of the more recent applications for this device is the movement of a thread guide in a yarn package winder and speeds of 900 traverses/min. have been achieved in laboratory models.

Returning for a moment to the idea of 'unrolling' a conventional induction motor to obtain a linear machine, if we could roll up the linear machine about an axis perpendicular to the original we should make a tubular motor in which the field travelled, as it were, up the 'barrel', for we have made a form of electromagnetic gun. Elementary forms of tubular motor without any iron in the stator are very simple to construct but very wasteful of power. For example, a gun 8 ft. long which can fire a 2-lb. dart at 100 m.p.h. consumed 200 amps/phase at 440 volts line. Well-designed tubular motors with good magnetic circuits have been used for pumping liquid metal in atomic power stations.

Two further applications of linear motors are at present under consideration. In the first, the motor drives directly on to a flexible metal belt. This is the conveyor drive. The obvious advantage is that belt slip is impossible since the force is not imparted to the belt through rollers or other friction-dependent device, but through space over a large area of belt. Unfortunately, most conveyors are too slow to exploit the device to its best advantage.

The second application is concerned with electric traction. The arrangement is virtually the same as that of the conveyor, except that the secondary conductor is fixed and the energized coils are allowed to move. A pair of linear motors is mounted on either side of a conducting rail as shown in Fig. 5. Such a traction unit would be completely devoid of moving parts. The rotor losses of a conventional induction motor, which prevent the machine from having the high starting torque required for traction, are no longer a problem with the linear drive, for the 'rotor' in this context is the conducting rail which, as it is heated, is left behind to cool and fresh cold

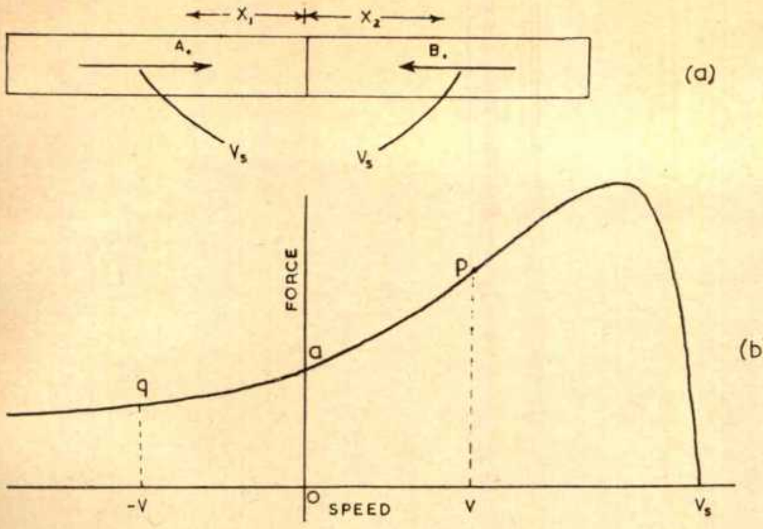

Fig. 4. Principle of the self-oscillating induction motor

rotor is continuously being fed into the motor as the vehicle moves. The first experimental track in the University of Manchester is shown in Fig. 6. The unit develops about 200 lb. of thrust up to a speed of 25 m.p.h. A second model, designed to have 1,000 lb. of thrust up to 33 m.p.h., is at present under construction in collaboration with the British Transport Commission.

In speculating about the future of linear motors it may be convenient to divide them into three classes, the first of which consists of high-powered, high-speed devices. These are likely to be relatively few, but the train may be one of them. In the second class are included all devices of effectively zero output. If the output is zero the efficiency is zero and one is only concerned with doing a job. The package winder is one example. Devices for producing push at negligible speed also fall into this class, and these could be very important. One American firm is producing a tubular actuator which produces a 2-lb. push, continuously, for 80 watts of input in a device weighing 7 lb. and costing at the present time £20.

The third class of linear motor which has a chance is the device for producing energy. Rocket launching is one such example. The object is not to produce power output, although power is needed—not to produce force—although force is needed, but to produce $\frac{1}{2}mv.^2$. Here it must be remembered that it is a fundamental of induction machines that for every joule of output energy produced, at least one joule is lost in heating the rotor and this may well exclude it as a serious proposition for rocket launching.

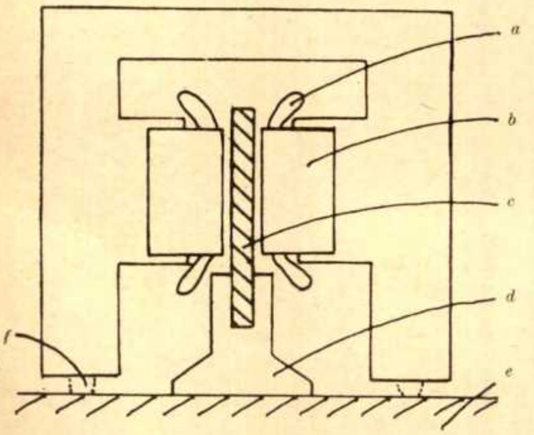

Fig. 5. Cross-section of experimental railway traction unit using linear induction motors
a, Stator coils; *b*, stator core; *c*, conducting rail; *d*, rail clamp; *e*, concrete 'road'; *f*, weight-supporting device (wheels or air-jets)

Of future developments in the broader field of electrical machines than that of the linear induction motor, the search for efficient continuous speed control of a brushless motor continues and may finally succeed.

Electronics and power engineering have now joined forces, and the new semi-conductor devices at power-level are opening up many new possibilities in the field of machines. Some of these are bound to prosper.

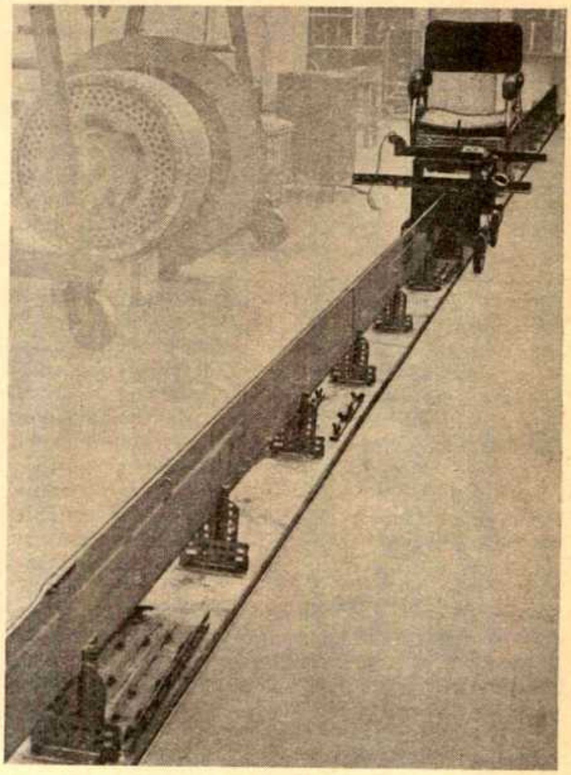

Fig. 6. Experimental railway traction layout in the University of Manchester

In an even broader field, some interesting electrical machines of the electrostatic kind may emerge. Recent work of zoologists on the reactions of living things to alternating electrostatic fields has suggested that control of emotions may not be outside the scope of this kind of machine. There is a real challenge for the electrical engineer, with possibly greater opportunities than in any time in the past, for the stakes are higher and the prizes so much the greater.

FUNDAMENTAL CANCER RESEARCH

THE sixteenth annual symposium on fundamental cancer research was held at the M. D. Anderson Hospital and Tumor Institute, Houston, during March 1–3, and its title ("Conceptual Advances in Immunology and Oncology") is indicative of the renewed interest in the immunological approach to the problem of cancer. It is equally significant that two out of the three days should have been devoted to fundamental immunology: even those who remain profoundly sceptical of the possibility of an all-embracing immunological interpretation of the cancer problem must concede that many of the techniques used in immunology are proving to be of immense value in its study.

The conference began auspiciously with discussions by Sir Macfarlane Burnet and F. Haurowitz on theories of immunity, one taking up the cudgels on behalf of an elective theory implying some kind of genetically built-in cellular responsiveness which is merely triggered off by antigen, and the other championing the instructive theory, which postulates that it is antigen, acting as a template, which impresses specific complementariness on the newly formed γ-globulin of cells. Burnet made it clear that although he could no longer believe in the truth of the clonal selection hypothesis as originally proposed by himself he still felt that the experimental evidence—not least his own, concerned with graft-against-host reactions of cells transplanted to the chorioallantoic membrane of the chick embryo—pointed to an elective theory; it would be extremely difficult to reconcile any other kind of theory with the fact that, during the course of development, the body 'learns' not to react against its own substances. Haurowitz, on the other hand, described experiments which indicate that antigen may persist intracellularly for many months and that antibody may be formed in very small amounts as long as one year after primary stimulation with bovine serum albumin. He felt that re-interpretation of the anamnestic response with these facts in mind was perfectly in line with the idea that antigen acts in an instructive capacity. However, both speakers agreed that at present there could be no final proof either one way or the other, and that in the last analysis a compromise between these two concepts may turn out to be nearest to the truth.

To fill the gap in the programme caused by the regrettable absence of N. K. Jerne, several short papers were read by the 'home team'. Of these, the most relevant to the problem of antibody formation was that of J. J. Trentin, who outlined a technique which, he thought, should at last provide a conclusive test of the clonal selection hypothesis. The technique entailed the re-population of the lymphoid organs of lethally irradiated mice with cells thought to belong to a single 'clone' and the subsequent challenge of these mice with four *Shigella* antigens. In giving his results, Trentin was careful to stress that much work remained to be done before they could be accepted as conclusive; but it appeared that the majority of a small number of mice was able to respond to several of the antigens. However, the crucial assumption—that the cells were, in fact, derived from a single donor strain cell—remained to be proved.

One of the most exciting advances in recent years has been the recognition that certain diseases such as Hashimoto's disease and acquired hæmolytic anæmia are caused by autoimmune responses, and a number of other diseases are now strongly suspected of an autoimmune origin. In discussing theories of autoimmunity, W. Dameshek suggested that experimentally induced 'runt disease' (which is due to the immunological response of genetically foreign lymphoid cells against the tissue antigens of the host) provided a revealing model for the autoimmune disorders. Autoimmunity could be antigen-mediated as in thyroiditis, which is almost certainly made possible by the fact that antigen in the form of thyroglobulin is sequestered during embryonic development and is therefore unable to induce immunological tolerance in the body's antibody-forming cells; or it could be due to abnormal immunologically competent cells owing their existence either to genetic causes or to somatic mutation.

Several papers were devoted to the control mechanisms of antibody synthesis. In describing the detailed cellular changes which occur when antigen is introduced into sensitized animals, F. J. Dixon provides the morphological background against which all immunological reactions must be viewed. He particularly stressed the fact that the nature of the morphological changes depends to a very large extent on whether immunity is mediated through cells or through serum. D. H. Sussdorf critically reviewed past and present experiments designed to reveal antibody activity in cell-free systems and pointed out many of the pitfalls inherent in experiments of this kind. R. W. Dutton described a series of experiments revealing the capacity of sensitized spleen cells to synthesize deoxyribonucleic acid (DNA) *in vitro*: addition of antigen stimulated the incorporation of thymidine labelled with carbon-14 into the DNA of the spleen cell, a phenomenon which was specific for the antigen with which the cell donor had been sensitized. Increase in thymidine incorporation was accompanied by an increase in the number of engaged cells rather than by an increase in the degree of incorporation by the same number of cells.

The properties of interferon (first uncovered by A. Isaacs at the National Institute for Medical Research, London) were comprehensively reviewed by S. E. Grossberg. Interferon was the name given to certain proteins produced by cells after exposure to viruses, and these substances had the power to protect other cells against infection. The resistance conferred by interferon was non-specific for virus, but it showed a curious species-specificity in the sense that interferon extracted, for example, from mouse tissues would not protect chicken cells. The action of interferon was intracellular, for it had been shown not to affect virus adsorption and penetration; nor was it, in all probability, able to influence release of virus. Although its action was still far from clear, Grossberg suggested that it might well be based on the uncoupling of oxidative phosphorylation.

R. S. Schwartz discussed the chemical suppression of immunity, that is, the elimination of the immunological response by prolonged treatment with antimetabolites such as 6-mercaptopurine. Although in a limited clinical study some of the patients suffering from hæmolytic anæmia responded well to chemotherapy, Schwartz went out of his way to stress the fact that, owing to the toxicity of the drug, treatment of this kind could be applied only with the most expert clinical and laboratory supervision. He also raised the interesting if speculative point that treatment of tumour-bearing patients with chemical agents capable of suppressing immunological responses might well deprive the patient of the means of resistance to the tumour.

A whole day was set aside for the discussion of the nature of the antigen–antibody reaction. C. W. Parker explained that for certain kinds of antigen–antibody reactions the spectrofluorometric method, which depends on a decrease in fluorescence when antibodies specifically interact with haptens, has important advantages over other methods. Using this method he had confirmed that R. R. Porter's immune γ-globulin fractions I and II (produced by digestion with papain) titrated as 'univalent molecules', but that fraction III was inactive. J. J. Cebra showed that water-insoluble papain may be used to great effect in the examination of the structure of antigen–antibody complexes, their molecular weights and the valence of the antigens. That the treatment of antibody with pepsin, followed by reduction of a single highly labile disulphide bond, can produce fragments closely resembling Porter's fractions I and II was demonstrated by A. Nisonoff, who went on to describe the formation of 'hybrid' antibodies by the oxidative coupling of univalent sub-units obtained from antibodies of two different specificities. Nisonoff also presented evidence suggesting that hybridization had occurred as a result of random recombination.

Z. Ovary described experiments which showed that although non-aggregated low molecular weight haptens with one determinant group did not provoke passive cutaneous anaphylaxis they could inhibit it, as well as neutralize *in vitro* specific rabbit or guinea pig antibody. When a second determinant group was added *in vitro*, neutralization was again complete but *in vivo* results were variable: with some guinea pig and rabbit sera the hapten now provoked passive cutaneous anaphylaxis, whereas with other guinea pig sera it acted only in the feeblest manner.

The chemical nature of the combining site of antibody molecules was discussed by D. Pressman, who made the point that owing to the heterogeneity of antibodies the study of anti-hapten antibodies was of the greatest value; unlike antibodies directed against proteins or other natural substances, such antibodies were directed against a single known chemical grouping. Pressman also said that there was now reasonable evidence from pepsin and papain experiments indicating that antibodies of even a single molecular weight may be of several different types, and that the fractions discovered by Porter were more complex than had originally been thought. J. R. Marrack suggested that the formation of aggregates, joined by specific bonds between bivalent antigens and multivalent antibodies, was not sufficient to account for precipitation. One of several possible reasons for failure to precipitate was the possibility that, because antigens carried determinants of various kinds, univalent antibody to one of the determinants was present in the system.

Finally, O. J. Plescia explained that although pure DNA had not been shown to be antigenic, it had been possible to prepare it in an immunogenic form from *Brucella abortus*. Several antigens were associated with this DNA; those susceptible to treatment with DNase were almost certainly DNA-carbohydrate complexes which could be dissociated only with the greatest difficulty, and the released DNA had comparatively little antigenicity. The antigenic groups were therefore unlikely to be part of the DNA molecule.

The highlight of the symposium was the presentation of the Bertner Foundation Award to G. D. Snell, director of the Roscoe B. Jackson Memorial Laboratory—an award given for outstanding achievement in the field of cancer research. In his Foundation Lecture on the immunology of tissue transplantation, Snell gave a comprehensive and up-to-date survey of a field which is continuing to change very rapidly and to which he and his colleagues have made such important contributions. He stressed that it had become necessary to distinguish between two kinds of immunological response, the one mediated through conventional serum antibodies and the other through antibodies associated with circulating lymphoid cells. Although both responses frequently occurred side by side, leukotic cells and normal lymphoid cells were susceptible to serum antibodies whereas most solid tumours and normal tissues such as skin were susceptible only to a cellular immunity. Snell also reviewed the phenomenon of immunological enhancement and made it clear that he and his colleague, H. J. Winn, had come to the conclusion that enhancement was brought about by central inhibition of the immunological response by serum antibodies.

Snell's lecture set the scene for a session devoted to tissue transplantation and immunological tolerance. L. Brent described experiments which confirmed that unresponsiveness to skin homografts can be brought about in adult mice by repeated injection of allogeneic hybrid spleen cells. He and G. Gowland had analysed this unresponsiveness and had come to the conclusion that it had almost all the properties of neonatally induced tolerance; although different methods had to be used to induce them, these two phenomena were probably identical at a cellular level. J. J. Trentin and J. Session described experiments using chromosome marker methods which indicated that in mice made tolerant at birth with allogeneic spleen cells the lymphoid tissues were largely repopulated with donor strain cells. They also found that tolerance of skin grafts was more durable when it was induced with hybrid rather than with parental strain cells. That donor cells persist in mice made tolerant with lymphoid cells either at birth or in adult life was demonstrated very clearly by C. Martinez, who used the spleens of tolerant mice to induce tolerance of donor strain antigens in isogeneic new-born mice. The degree of repopulation of the hosts' lymphoid tissue depended largely on the genetic relationship between donor and recipient strains and also on the manner in which tolerance had been brought about in the first instance.

M. W. Chase reviewed the work he and his colleagues had done on the acquisition of immunological tolerance of simple chemical allergens such as picryl chloride; guinea pigs repeatedly fed with such substances were unable to [illegible] to the allergen with a delayed-type contact hypersensitivity or with circulating antibodies. When especially powerful antigens were used abundant serum antibody was formed but inhibition of delayed hypersensitivity remained unaltered. Chase felt that present theories of tolerance would have to be amended so as to take these facts into account. In a most interesting contribution, M. Feldman explained that he and his colleagues had shown that the immunological responsiveness of sub-lethally irradiated rats could largely be restored by the injection of cells from normal animals together with the antigen (sheep red blood cells). This was also true for rats made unresponsive to human serum albumin by treatment with 6-mercaptopurine: immunological responsiveness could be restored not only with spleen cells but with cell-free extracts and DNA-digests as well. Feldman believed that these experiments were incompatible with the clonal theory of tolerance.

The final session was concerned with the question of cancer-specific antigens. The papers by K. Habel and H. O. Sjögren were beautifully complementary in demonstrating that the cells of tumours induced by polyoma virus possessed a new antigen which was foreign to the host. The experimental evidence was partly based on the observation that mice can be made resistant to the tumour by pre-treatment with the virus or with virus-induced tumour cells; but Habel also showed that resistance could be transferred with lymph node cells but not with serum from resistant mice, and that tolerance of the cellular antigen could be induced in new-born mice. In addition, Sjögren confirmed that methylcholanthrene-induced tumours, too, have a new cellular antigen. The antigenic properties of methylcholanthrene-induced tumours were discussed by R. T. Prehn, who stressed that, in contrast to polyoma virus-induced tumours, immunological cross-reactions among various tumours were rare. The fact that antigenicity was sometimes lost after repeated transplantation suggested the possibility that non-antigenic tumour cell variants had been selected by a hostile environment. Prehn suggested that several experimental observations indicated that one of the principal facets of carcinogenic activity might be the suppression of immunological responsiveness by the carcinogens.

B. Björklund described the production in horses of a cancer-specific antiserum following sensitization with sixty human carcinomas. This antiserum was specific for human neoplastic cells because its cytotoxic activity was retained after absorption with normal human cells. Björklund's conclusion that human carcinomas are characterized by specific antigens was not accepted by all immunologists present.

W. Braun *et al.* claimed to have shown that DNA digests from calf thymus or the spleens of very young mice reduced the incidence of spontaneous tumours when injected repeatedly into young mice. Furthermore, pretreated mice rejected transplantable tumours obtained from untreated old mice—a finding which was complicated by the observation that the same animals died more quickly of growing tumours when challenged for a second time two months later. Finally, R. H. Wilson described a clinical study in which 32 patients with terminal malignant disease were injected with their own tumour cells emulsified with hyaluronidase and Freund's adjuvant. A rise in specific serum antibody titre occurred in 20 patients, and Wilson *et al.* concluded that a specific antigen must have been present in the neoplastic cells of these patients.

The symposium was attended by many hundreds of cancer research workers, and it undoubtedly succeeded in giving them an excellent bird's-eye view of the manifold new developments in immunology and cancer research. However, the very size of such a conference seriously limits the value of the discussions, and this is to be regretted.

LESLIE BRENT

OBITUARIES

Mr. Fred Scholefield, M.B.E.

FRED SCHOLEFIELD, who died on March 10 at his home in Hale, Cheshire, at the age of seventy-eight, and who spent almost the whole of his long professional life in the service of tinctorial technology, will best be remembered as the head of the Department of Textile Chemistry in the College of Science and Technology, Manchester, a department which he brought into being. He came late to the service of university education, for, after a meritorious performance as a student in the Departments of Chemistry and of Dyeing and Tinctorial Chemistry at the Yorkshire College (later the University of Leeds), he was for twenty-two years engaged in the industrial practice of textile dyeing and allied chemical treatments, becoming ultimately the chief chemist and works manager of Burgess, Ledward and Co., a large yarn-processing firm near Manchester.

In an old industry in which traditional usages and modern chemical and engineering discovery need to be promptly combined by the more enterprising firms, Scholefield foresaw more strongly than many of his generation the need for a much greater number of carefully and soun[illegible] trained technologists than seemed to be in p[illegible] end of the First World War. In 1926 he gave up his industrial position to join the Department of Applied Chemistry at the College, taking the place left vacant by the death of Edmund Knecht and the retirement of Julius Huebner. Soon after his arrival he was able to have a separate Department established, of which he was to remain the head until his effective retirement from academic work in 1951. During his régime the Department developed greatly in activity and importance, students came from many parts of the world and the record of research and teaching was very substantial taking into account the small numbers of his staff.

Scholefield's main interest in the field of dyeing research was in the oxidative changes brought about in cellulosic and other fibres when they were dyed with certain vat dyes, and activation occurred either by light or through other chemical agencies. Although later workers have extended our knowledge of the fundamental mechanisms on which these phenomena could be based, there is, even now, very little further understanding of the distinctive effects of specific dyes in actual textile products.

Scholefield was a lucid and inspiring teacher, a kindly, sociable and generous man, widely read and widely travelled, with many friends in Britain and abroad. He had unusual powers of analysing a complex situation and giving his opinion in precise and graphic terms. This, coupled with his retentive memory and his liberal outlook, made him particularly effective in committee. During the whole of his professional life, he was an active member of the learned societies appropriate to his interests. He served two terms on the council of the Royal Institute of Chemistry and was chairman of its Manchester and District Section; he was a founder-member and past president of the British Association of Chemists and did a great deal of work to forward its interests with which he was greatly in sympathy. He was on a number of committees of the Textile Institute and the City and Guilds of London Institute, most of them concerned with technical education and professional status. The Textile Institute made him an honorary life member and awarded him the Institute Medal: the City and Guilds made him a special award of its insignia. The Society which made the strongest claims on his attention was the Dyers and Colourists, of which he was a member of council for many years and in the varied activities of which, local and national, he played a very special part. He held the Research Gold Medal of the Dyers' Company, the Society's own Gold Medal and was a honorary life member, and its president in 1950–51. One of his last public activities was as a member of the inter-society committee which organized the celebration of the Perkin Centenary. His former students, part-time and university, were widely scattered throughout the textile processing and allied industries in responsible positions, and during his later years he had many tokens of their gratitude and esteem.

On his retirement from academic life, he became technical adviser in Manchester to the Dyestuffs Office of the Board of Trade, and his wide knowledge of the dye-making and dye-using industries, with his many personal connexions in both, enabled him to give further valuable service to the tinctorial interests of Britain. For it he was made a member of the Order of the British Empire in 1959. In the past few years serious illness curtailed his activities; but on all occasions possible he attended at his office until final retirement in 1961.

He lived to see the Department that he founded increase greatly in size, equipment and numbers with the expansion of the College itself. He leaves behind many pleasant memories in all those who were his friends and associates.

H. A. TURNER

Mr. W. G. Kendrew

THE death on April 4 of W. G. Kendrew will be deeply regretted by climatologists and meteorologists throughout the world. For more than fifty of his seventy-seven years he took a great interest in climatology and his name soon became a household word in climatological circles. At Oxford, after taking a pass degree, he joined, in 1909, the teaching staff of St. Catherine's Society as classical don and eventually also as dean.

But Kendrew's main inspiration sprang from geography, in which in 1910 he gained with distinction the certificate and diploma. Geography at Oxford was then under Prof. A. J. Herbertson, who had transported personally to Britain the ideas prevalent in Germany on world climatic belts and regions. It is probable that Kendrew was impressed by public criticisms of Herbertson's speculative global schemes (1912), such as the desirability of 'avoiding' wherever possible sharp boundaries to thermal zones; of using accumulated and extreme temperatures rather than averages; of taking account of rainfall and of evaporation, particularly from the human body. In any event, Kendrew turned to the more quantitative study of the climates of individual areas, and on these and climatic principles he lectured and tutored, with breaks for War service, from 1912 until 1950, the last ten years as reader in climatology.

Whatever he said or wrote reflected his classical leaning and his geographical enmeshment. It was highly intelligible, carefully and concisely phrased, and geographically rather than meteorologically applied; his use of quotations and his translations from foreign texts were brilliant; his technique of providing, prominently, but not too disruptively, a simple statistical basis to climatic phenomena inspired confidence. Consequently, the general public and the non-specialist student found his expositions attractive and most helpful.

His earlier climatic writings appeared in Herbertson and Howarth's *Survey of the British Empire* (1914). Within eight years these regional accounts had been extended to all the land-masses and *The Climates of the Continents* began its long career. The book aimed at filling a gap caused by the lack in English of any adequate description of the actual climates of the countries of the Earth, considered regionally. It was hailed as 'a pioneer work of its class' and of great value as bringing together in one volume a vast amount of information. A fifth edition, considerably revised and enlarged, appeared in 1961 and to date about 30,000 copies in all have been sold.

In the meantime, Kendrew, although well aware of the existence of several excellent works on the subject, compiled *Climate* (1930), a systematic account of the general principles of climatology treated mainly from a geographical and distributional point of view. A leading British meteorologist welcomed, *inter alia*, the valuable chapter on humidity and temperature in relation to the human body and thought the volume very readable and probably the best and then most up to date of its particular scope and purpose. What was virtually an extensively rewritten third edition appeared as *Climatology* in 1950 and was revised in 1957.

On retiring from Oxford, Kendrew worked for some years in Canada for the Government, in rewriting for general use the detailed reports by specialist investigators of climatic conditions in parts of that country. In 1955 the results, *The Climate of Central Canada* (with B. W. Currie) and *The Climate of British Columbia and the Yukon Territory* (with D. Kerr), evoked warm appreciation for the readily available data, the condensation of a vast mass of statistics, and the undoubted suitability for the general public of the illuminating and invitingly readable narrative.

Kendrew will long be remembered as an outstanding advocate and exponent of climatology, but his practical qualities should not be ignored. From 1935 until 1950 he directed the Radcliffe Meteorological Station at Oxford and he was a life-long connoisseur of weather and skyscapes. Partly in pursuit of climatic experience, he travelled widely, and for him there was always, besides meters and gauges, the human recorder, if possible in the form of Wilfrid George Kendrew.

R. P. BECKINSALE

NEWS and VIEWS

Molecular Biology at Cambridge

H.M. THE QUEEN opened the Medical Research Council's Laboratory of Molecular Biology, Cambridge, on May 28. The Laboratory, which is situated about two miles from the centre of Cambridge, has been built in association with the new accommodation for the University Department of Radiotherapeutics on the site of the new Addenbrooke's Hospital in Hills Road, and these buildings also were opened by the Queen. The Medical Research Council were represented at the ceremony by its chairman, the Right Hon. Lord Shawcross, and secretary, Sir Harold Himsworth.

The Council's Laboratory provides new permanent accommodation for the staff of the former Molecular Biology Research Unit, which was set up in 1947 in the Cavendish Laboratory at Cambridge, and has made outstanding contributions to knowledge about the structure of proteins and nucleic acids and in the field of molecular genetics. In the new Laboratory, the Unit's research workers will be joined by others who have been working in the same field. These will include the team led by Dr. F. Sanger, whose work on the chemical structure of insulin gained him a Nobel Prize in 1958, and who has until now been a member of the Council's staff at the School of Biochemistry, Cambridge, and by another member of its staff, Dr. H. E. Huxley, formerly at University College, London, who is well known for his discovery of the mechanism of muscular contraction. Dr. J. D. Smith, at present at the Biological Division of the Californian Institute of Technology, distinguished for his work on the chemistry of nucleic acids, and Dr. A. Klug and his virus research group from the Physics Department at Birkbeck College, London, will also be joining the Laboratory. The Laboratory will be under the general direction of a small committee, composed of the heads of divisions, under the chairmanship of Dr. M. F. Perutz. There will be three main divisions: (*a*) Structural Studies under Dr. J. C. Kendrew; (*b*) Molecular Genetics under Dr. F. H. C. Crick; (*c*) Protein Chemistry under Dr. F. Sanger.

U.S. National Bureau of Standards :
Dr. J. A. Simpson

DR. JOHN A. SIMPSON has been appointed chief of the Electron Physics Section at the National Bureau of Standards, U.S. Department of Commerce, in succession to Dr. L. L. Marton, new chief of international relations. Born in Toronto, Ontario, in 1923, Dr. Simpson received his secondary education in Stratford, Conn. He attended Lehigh University in 1940 under the New England Regional Scholarship. After serving in the Army Signal Corps during the War, he returned to Lehigh, receiving his B.S. in engineering physics in 1946 and his M.S. in physics in 1948. He then joined the staff of the National Bureau of Standards, where he has conducted research in electron physics with special emphasis on instrumentation. His dissertation for Ph.D. at Lehigh University in 1953 was based on his work on the electron interferometer. He has also published on electron optical schlieren problems and on the characteristic energy-losses of electrons in metals.

Nuclear Tests and the World Federation of Scientific Workers

THE president of the World Federation of Scientific Workers, Prof. C. F. Powell, has issued a statement calling for the stopping of all nuclear tests and for further expert assessment of the possibility of identifying tests. The Federation, which links 200,000 scientists in 32 countries, expresses grave concern at the resumption of nuclear tests in the atmosphere and does not understand how the possibility which still remains of concealing the smallest underground nuclear tests can be rationally used to justify the resumption of atmospheric tests on the largest scale which undoubtedly cannot be concealed. The statement asserts that the resumption of atmospheric tests gravely prejudices the possibility of progress in general disarmament; facilitates the acquisition of nuclear weapons by powers not at present possessing them; constitutes a biological hazard through dangers from fall-out; and is likely to lead to a further deterioration in international relations and an intensification of the cold war.

The Federation welcomes the initiative of the representatives of the neutral powers at the Geneva Conference in suggesting a compromise solution to the differences between the Anglo-American and Soviet positions on nuclear tests. In view of recent advances claimed in the identification of small underground explosions, the Federation calls, as an urgent measure, for the establishment at Geneva of another conference of scientific experts to assess the present position with regard to the detection of nuclear tests, using only national detection systems supplemented by international monitoring stations on the territories of uncommitted powers willing to accommodate them. Pending the presentation of the report of such a conference, the statement urges all nations to refrain from further nuclear tests of any description. The statement has been sent to heads of States already possessing nuclear weapons, to the United Nations, and to the heads of all Delegations to the Geneva Conference on Disarmament.

U.S. Projects on Economic and Social Implications of Science and Technology

Current Projects on Economic and Social Implications of Science and Technology, 1961, issued by the National Science Foundation, is the third in a series of annual surveys of projects relating to some aspect of social-science research on science and technology (NSF-62-4. Pp. vii+116. Washington, D.C.: Government Printing Office, 1962. 40 cents). The surveys, which are based on investigators' reports of their projects, supplement the Foundation's programme of statistical studies. Of the 262 projects listed, only 40 are financed solely by the investigator and more than 200 have full or partial financial support outside the Foundation. The projects are classified under 14 subject headings and there are indexes of authors and of institutions.

Industry in Katanga

A COLLECTION of papers on the industries of Katanga has recently been published in French by the State University of Elisabethville (Publications de l'Université de l'État à Élisabethville. 2: *l'Industrie Katangaise—Réalisations et Perspectives*. Pp. vi+404. Elisabethville: Université de l'État à Élisabethville, 1961). These were read at a conference held last July in connexion with the celebrations of the fiftieth anniversary of the foundation of the City of Elisabethville, and together they provide an authoritative and detailed survey of practically all aspects of the country's economy, including transport, electricity production and transmission, agriculture, mining, the metal and chemical industries, building, and the food industries. In a preface, the Rector of the University (M. J. Frenkiel) points out that, in the older countries, collaboration between universities and industry has had very beneficial effects on both parties, and in particular it has been especially helpful to small and medium-sized firms which cannot afford to provide their own research laboratories. Similar collaboration, he emphasizes, is even more valuable in a young country such as Katanga. A concluding paper on the principal characteristics, structure and prospects of Katangan industry by Prof. René Clemens and M. Grosjean, of the University of Liège, provides thoughtful comment not only on the specific problems of Katanga's economy but also, more generally, on problems of economic progress in under-developed countries. The authors of this paper stress the importance of the formation of capital, the encouragement of private investment and the development of a spirit of enterprise receptive to modern technical and commercial methods among workers conditioned in the past to traditional modes of life.

Adult Education in Britain

THE report of the Universities Council for Adult Education for the academic year 1960–61 refers to some studies of the character of students made in Nottingham, Newcastle and Leeds (Pp. 24. Liverpool: Universities Council for Adult Education. 1962). The Nottingham survey indicated that students were distinguished chiefly by their minority interests and were drawn predominantly from the professional middle class. Leeds reported a trend for women students to outnumber men considerably, and also that 43·1 per cent of students in grant-aided extension courses had received full-time education up to training college or university, while a further 31·7 per cent had stayed at school beyond the minimum leaving age. Extra-mural departments have arranged a growing number of courses for specific vocational groups, some of these being at post-graduate level and often in close collaboration with internal university departments. The Younghusband report has stimulated consideration of the part to be played by university extra-mural departments in the education and training of social workers, and, besides refresher courses of a similar type, departments have undertaken courses to meet special needs, including courses for Children's Officers, hospital administrators and officers of the National Assistance Board. Particular reference is made to the development of day-release courses, including liberal studies, and stress is laid on the importance of teaching being given by full-time university tutors. Besides the four weeks course for managers in industry arranged by the University of Cambridge at Madingley Hall, the "Background to Management" courses in Manchester continued and there are three established seminars for business men in Birmingham, while Edinburgh continued its seminars for management and at Sheffield an evening course in industrial relations led to a request for a course for management staff inside a factory. A survey of science in extra-mural studies in the Bristol area indicated that science represented 26 per cent of the programme in 1960–61 compared with 12 per cent 10 years ago. Eight departments referred particularly to local history, and in Belfast and Scotland language teaching has developed notably, for example, as a medium for studying a modern country. While there is evidence of the particular value of residential centres, non-residential centres still have their place and the importance of proper centres is emphasized, as is the need for more full-time tutors.

Sugar Beet Farming in Britain

IN replying for the Government in a debate on May 2 on a motion to annul the Sugar Beet (Research and Education) Order, 1962, the Joint Parliamentary Secretary to the Ministry of Agriculture, Fisheries and Food, Mr. W. M. F. Vane, welcomed the debate as directing attention to the valuable research, covering diseases and sugar content, in which the Imperial College of Science and Technology and the University of Nottingham, as well as Rothamsted Experimental Station and other research stations, had participated. The industry had taken the initiative throughout, and between 1942 and 1961 the average yield of beet per acre had risen from 9·4 to 13·4 tons, while virus yellow had become much less of a menace and methods of control had improved. Disease and fertilizer experiments previously carried out by the Dunholme Field Station, Lincolnshire, of the Rothamsted Experimental Station were being transferred to a new field station at Broom's Barn, Higham, near Bury St. Edmunds. This would be a permanent station with more opportunities for research, which would be concentrated mainly on problems concerning sugar beet. The Order required the Minister in framing the research programme to consult the Sugar Beet (Research and Education) Order, which since 1942 had worked well. Mr. Vane said that the £14,000 going to the plant breeding station at Cambridge and other items in the Schedule were financed by the levy authorized by the Order, and the motion was withdrawn.

The Zoological Society of London: Annual Report

IN its annual report for 1961 (Pp. 56+8 plates. London: H.M.S.O., 1962), the Zoological Society of London directs attention to the continuing excellence of the health and welfare of the animals in the collections, and the new high level of attendances at Whipsnade. Problems of buildings are also discussed. Each new house has its own problems of structure and design according to the strength, behaviour and best methods of display of the animals it has to shelter. There is also the æsthetic problem to contend with. One of the most complicated buildings now to be built is a new Small Mammal House. To allow adequate time for research, the Council of the Society has commissioned Prof. Misha Black, professor of industrial design (engineering) at the Royal College of Art, to design a building in which nocturnal, jumping, burrowing and flying mammals can be suitably exhibited and studied. Dr. I. W. Rowlands has been appointed Senior Research Fellow in reproductive physiology, and will be in charge of the Wellcome Institute of Comparative Physiology. Five other Research Fellows and two Research Students in the physiology of animal reproduction were appointed during the year. These appointments have been made possible by the grant from the Ford Foundation.

Awards

NEW annual awards to be presented by the Society for contributions to zoology are: the Prince Philip Prize, to be awarded to a pupil of zoology in any school in Great Britain, Northern Ireland, the Channel Isles, and the Isle of Man, on the basis of an account of some practical work in the field of animal ecology; the Stamford Raffles Award, commemorating the Founder of the Society, to be awarded to an amateur zoologist for contributions to zoology, or to a professional zoologist for contributions which extend beyond his field of specialization; and the Thomas Henry Huxley Award, to be awarded to a postgraduate research student in any university of Great Britain and Northern Ireland, for outstanding original work in zoology submitted as a doctoral thesis. The prize and two awards will consist of sculptures by Mr. Henry Moore. Further information can be obtained from the Secretary of the Society,

International Commission on Zoological Nomenclature

NOTICE is given of the possible use by the International Commission on Zoological Nomenclature of its plenary powers in connexion with the following cases, full details of which will be found in *Bulletin of Zoological Nomenclature* (19, Part 3 to be published on May 28, 1962): (1) Validation of the generic name *Doto* Oken, 1815 (Gastropoda). *Z.N.*(*S.*) 1006. (2) Validation of the specific name *caricae* (*Cynips*) Linnaeus, 1762 (Insecta, Hymenoptera). *Z.N.*(*S.*) 1047. (3) Validation of the generic name *Lystrophis* Cope, 1885 (Reptilia). *Z.N.*(*S.*) 1484. (4) Designation of a neotype for *Gryllus campestris* Linnaeus, 1758 (Insecta, Orthoptera). *Z.N.*(*S.*) 1485. (5) Validation of the specific name *alveofrons* (*Dasiops*) McAlpine, 1961 (Insecta, Diptera). *Z.N.*(*S.*) 1492. (6) Designation of a type-species for *Pisidia* Leach, 1820, and suppression of the specific name *istrianus* (*Cancer*) Scopoli, 1763 (Crustacea, Decapoda). *Z.N.*(*S.*) 1496. (7) Validation of the generic name *Stereomastis* Bate, 1888 (Crustacea, Decapoda). *Z.N.*(*S.*) 1497. (8) Suppression of the generic name *Arctopsis* Lamarck, 1801, and the specific names *lanata* (*Arctopsis*) Lamarck, 1801, and *tribulus* (*Cancer*) Linnaeus, 1767 (Crustacea, Decapoda). *Z.N.*(*S.*) 1498. (9) Validation of the generic name *Ophiophagus* Günther, 1864 (Reptilia). *Z.N.*(*S.*) 1500. (10) Suppression of Dahl's "Coleoptera und Lepidoptera", 1823. *Z.N.*(*S.*) 398. (11) Suppression of Kishida's pamphlet *Notes on the Family Trombidiidae of Japan*, 1909. *Z.N.*(*S.*) 400. Any zoologist who wishes to comment on any of the above cases should do so in writing to the Secretary, International Commission on Zoological Nomenclature, c/o British Museum (Natural History), Cromwell Road, London, S.W.7.

National Survey of Air Pollution

URBAN conditions do not necessarily preclude a high standard of purity of the air according to the Department of Scientific and Industrial Research Warren Spring Laboratory. Commenting on measurements of air pollution made in 1958–59, the Laboratory says that figures show that, even in large manufacturing towns, including London, the annual average of the smoke concentrations at certain sites was less than half the annual average for urban areas over Britain as a whole (about 200 millionths of a gramme per cubic metre of air). Sites in the centre of Wolverhampton and in Woolwich are among the places singled out for their freedom from smoke pollution. At a site in the centre of Wolverhampton, the average concentration during the year (expressed as millionths of a gramme per cubic metre of air) was 59; at a site in Woolwich it was 72, compared with an average of 219 over the whole of London. "Results such as these show the basic soundness of the policy of smoke-control areas. Improvements in one area are not nullified, though they can be affected, by smoke drifting in from neighbouring districts" (*Report of Warren Spring Laboratory* 1961—Report of the Warren Spring Laboratory Steering Committee and the Report of the Director of Warren Spring Laboratory for 1961. Pp. vi+34+8 plates. London: H.M.S.O., 4*s.* net, 1962). One in four of the towns in the North of England where measurements were made in 1958–59 had annual average concentrations of more than 300 millionths of a gramme of smoke per cubic metre of air. To obtain a really comprehensive picture of the distribution of air pollution throughout Britain, the Warren Spring Laboratory is organizing a National Survey of Air Pollution, with daily smoke and sulphur dioxide measurements being made at more than 1,000 sites in all parts of Britain, including a statistically chosen representative sample of towns of all sizes in England and Wales. Many of the local authorities co-operating in this Survey are already taking measurements and others are installing apparatus.

Guide to Careers

IN this year's edition of the National Union of Teachers' *Guide to Careers for Young People*, the bulk of the contents are devoted to information about particular careers and fields of employment, rather than to advice about aspects of careers guidance, preparation for employment and the sources of careers information (Pp. 84. London: National Union of Teachers. 3*s.* 6*d.* 1962). This is an experiment, undertaken after considering suggestions from a number of schools which use the *Guide*. There is an even greater need for this *Guide* now than there was at its inception. The emergence into employment of the children of the 'bulge' years means that there are many more young people to inform and advise about careers. An even more compelling indication of the need is the situation revealed by two recent surveys conducted among young people in their first year of employment. These have provided evidence of young girls and boys obtaining jobs generally bearing little relation to the jobs they aimed at, or being far from clear about what work was entailed in different occupations, of employers not giving any details of job offered, or giving inaccurate information or misusing the term 'apprenticeship'. No one concerned with the task of passing on careers information, least of all careers masters and careers mistresses, can be satisfied with this state of affairs. For individual children these surveys point to unhappiness, frustration, restlessness, smouldering discontent; for a nation which needs to utilize all the talent and skill in its citizens, they reveal untapped potential and wasted and half-used resources. The *Guide* should play a part in ensuring that the boys and girls shall be better prepared for their future employment.

British Section of the Society of Protozoologists

At the first meeting of the newly formed British Society for Parasitology, which was held at Cambridge during April 3–5, twenty-six protozoologists met to establish a British Section of the Society of Protozoologists. The first meeting of the Section will be held in the Department of Zoology, University College, London, on October 20. All those who are interested in Protozoa are invited to attend. The temporary administrative committee consists of: Mrs. K. M. G. Adam, Department of Zoology, University of Edinburgh; R. J. Cole, Department of Zoology, King's College, London; K. Vickerman, Department of Zoology, University College, London, from whom further information can be obtained.

The Institution of Mining and Metallurgy: Awards

The following awards have been made by the Institution of Mining and Metallurgy: *The Gold Medal of the Institution for* 1961, to Prof. F. A. Forward, in recognition of his contributions to the development of metallurgical processes, particularly that of pressure leaching; *Honorary Membership of the Institution*, conferred on Prof. W. R. Jones, past-president, in recognition of his distinguished services to the science of economic geology and to the Institution; *'The Consolidated Gold Fields of South Africa Limited' Gold Medal* for the session 1960–61, to K. C. G. Heath, for his paper entitled "Mining and Metallurgical Operations at Rhodesia Broken Hill—Past, Present and Future" (*Trans. Inst. Min. Metal.*, 70); *'The Consolidated Gold Fields of South Africa, Limited' Premium of Forty Guineas* for the session 1960–61, to Dr. J. A. E. Allum, for his paper entitled "Photogeological Interpretation of Areas of Regional Metamorphism" (*Trans. Inst. Min. Metal.*, 70).

Lederle Medical Faculty Awards

The Lederle Laboratories Division of the American Cyanamid Company is making available a number of medical faculty awards which will begin with the academic year 1963–64. These awards are intended only for individuals who share in all departmental responsibilities, particularly in the teaching of undergraduate medical students. They are not intended to be research fellowships, or for the support of individuals whose only or major function and interest is the conduct or supervision of research activities. They are also not intended for assistance of research departments or divisions of postgraduate medical schools, but are primarily for assisting medical schools in providing for their major clinical disciplines individuals who, having demonstrated interest and ability in teaching and research, will devote their major efforts to the teaching of clinical medicine with the view of integrating the knowledge and principles of the biological sciences, as applied to man. Further information can be obtained from Lederle Medical Faculty Awards, Office of the Secretary, Pearl River, New York.

Spectroscopy in the Metallurgical Industry

A symposium on "Spectroscopy in the Metallurgical Industry", arranged by the Spectroscopy Group of the Institute of Physics and the Physical Society in collaboration with the British Non-Ferrous Metals Research Association and the British Iron and Steel Research Association, will be held in Buxton, Derbyshire, during July 5–6. The programme will include: X-ray fluorescence analysis of copper alloys; X-ray fluorescence analysis in metallurgical research; mass spectroscopy; spectrographic control of nickel alloy production; control analysis in a steel works; control analysis for stainless steel production; analysis of high silicon steels with a vacuum spectrometer; spectroscopy in the assay of precious metals; spectroscopy in the German metallurgical industry. Further information can be obtained from Dr. L. Bovey, Building 329, Atomic Energy Research Establishment, Harwell, Didcot, Berks.

Announcements

The twelfth world poultry science congress will be held in Sydney during August 13–18. Further information can be obtained from the Ministry of Agriculture, Fisheries and Food, Whitehall Place, London, S.W.1.

The thirteenth session of the International Commission for Uniform Methods of Sugar Analysis will be held in Hamburg during August 26–31. Further information can be obtained from Dr. D. Gross, Tate and Lyle Research Laboratories, Keston, Kent.

The International Federation of Information Processing Societies Congress, 1962, is to be held in Munich during August 27–September 1. An exhibition of computers and other information processing will be held during the congress. Further information can be obtained from Dr. A. P. Speiser, IBM Research Laboratory, Zurichstrasse 108, Adliswil-Zurich.

The second international congress of radiation research, sponsored by the International Committee for Organizing Congresses of Radiation Research and the Association for Radiation Research, will be held in Harrogate during August 5–11. Further information can be obtained from Dr. Alma Howard, Mount Vernon Hospital, Northwood, Middlesex.

The 1962 Summer School in Infra-red Spectroscopy, organized by Unicam Instruments, Ltd., will be held in Cambridge during July 15–28. Residence will be in Gonville and Caius College, and practical tuition in sample handling and interpretation will be given in the laboratory of Unicam Instruments, Ltd., at the newly opened Scientific Centre. Further information can be obtained from Mr. D. E. Sheppard, Unicam Instruments, Ltd., York Street, Cambridge.

An interdisciplinary conference on "Electromagnetic Scattering", sponsored by the Division of Colloid Science and Surface Chemistry of the American Chemical Society and the Office of Aerospace Research of the United States Air Force, will be held in Potsdam, New York, during August 13–15. The programme will include the following sessions: scattering by spherical particles; scattering by non-spherical particles; scattering by charged species in solution; interactions in solids and liquids as determined by electromagnetic scattering; multiple and incoherent scattering. Further information can be obtained from Dr. Milton Kerker, Clarkson College of Technology, Potsdam, New York.

Erratum. In the article "Hazards of Dust", appearing on p. 244 of the April 21 issue of *Nature*, Prof. R. C. Browne reviews *The Relation between Pneumoconiosis and Environmental Conditions: an Analysis of the Results of the First Series of X-ray Surveys in the National Coal Board's Pneumoconiosis Field Research*. The authors of this report are D. Hicks, J. W. J. Fay, J. R. Ashford and S. Rae, and not the two latter only as printed in the review.

GAS CHROMATOGRAPHY

Recent Literature

PUBLISHED volumes on gas chromatography fall into four fairly well-defined classes. The first, proceedings of symposia, has become a well-established format for the publication of original papers in the field, and a higher proportion of the significant literature of the technique is concentrated in such volumes than in most other subjects. Compilations of abstracts form an extremely valuable small second class, providing a compact source of information on the technique. Thirdly, handbooks with a practical bias intended mainly for the beginner have been available since early in the 'fifties, the first, by C. S. G. Phillips, being followed by a succession of others which have, in general, kept well abreast of practical developments. It is in the last class of what can be called authoritative comprehensive texts that the technique is most obviously deficient. Keuleman's book is about the only representative of this latter group and even the second edition is, in many aspects, out of date. Six volumes recently published[1-6] reflect this distribution, including two symposia proceedings, one compilation of abstracts, two handbooks and a text on theoretical aspects, unfortunately, at present, only available in German.

The publication of papers presented at symposia in the form of a bound proceedings rather than in the normal scientific journals would seem to me to be justified only on the basis that they appear quickly as a compact group, and that the generally valuable and interesting discussion which follows their presentation is included. Unfortunately, the proceedings of the Second International Symposium organized by the Instrumentation Division of the Instrument Society of America[1] meets neither of these two requirements, its publication having been delayed more than eighteen months after the symposium and even then it is without the discussions, which had been included so effectively in the proceedings of the first symposium. The increase of nearly 50 per cent in price over the latter is also somewhat surprising.

These deficiencies are even more regrettable as the thirty-four papers presented cover almost every aspect of the technique. There are fewer papers of a theoretical character than might have been expected, but a treatment of band broadening effects in large columns by M. J. E. Golay should provide a useful basis for the improvement of preparative scale columns.

Many new developments in apparatus and technique are described with some emphasis on ionization detectors, which were still something of a novelty at the time of the meeting. Unfortunately, neither the improved Ryce and Bryce ionization detector nor the radio-frequency discharge detector, which are described in some detail, seems since to have achieved the reliability and sensitivity of the hydrogen flame or argon ionization detectors. An attempt is made to clarify the difficult question of comparing detector performance on a general basis. Both high-temperature operation and temperature programming are discussed and the use of column back-flushing illustrated. Column packings receive some attention both from the point of view of the influence of the support and for achieving specific separations. Among the latter, the use of liquid-modified adsorbents to separate low molecular weight olefines and the resolution of permanent gas mixtures with molecular sieves and active carbon are noteworthy. Several papers deal with the problem of identification of peaks using, in addition to retention data, such methods as micro-chemical tests and mass spectrometry. Useful ancillaries, such as an automatic fraction cutter and a precision integrator, are described.

Applications include process monitoring and control, the water content of hydrazine, the analysis of ortho-para hydrogen and the determination of dissolved oxygen in petroleum liquids. Illustrations of the use of a commercially available apparatus for preparative scale work are also given.

Finally, on a lighter note: all aspiring pioneers in science should read the after-dinner comments by A. T. James on his association with A. J. P. Martin which resulted in the discovery and early development of gas-liquid chromatography. This should be prefaced by a perusal of Martin's account in the proceedings of the first symposium, given in similar circumstances.

The proceedings of the third symposium organized by the Society for Analytical Chemistry and the Gas Chromatography Discussion Group[2] contains the twenty-nine papers presented at that symposium together with the discussion which followed them. The proceedings are divided into three sections, entitled "Apparatus and Technique", "Theory and Application" and "General Application", each prefaced by an introductory lecture presented by well-known workers in the field.

In introducing the first section, R. P. W. Scott outlines most of the aspects of the technique which still require development or clarification. Several useful papers on detectors follow with interest centred mainly on the argon and flame ionization detectors. A novel method of producing very low concentrations of volatile substances in permanent gases by diffusion, for the calibration of the latter, is described. An improved integrator provides a versatile facility for automatic quantitative interpretation of chromatogram and, for rapid elution, details of apparatus by which the elution curve can be displayed repetitively on a large cathode-ray tube are given.

M. J. E. Golay introduces the second section with a stimulating discussion of the future prospects of the capillary columns he originated and of the trends in the development of large columns for preparative purposes. Several other papers also describe recent advances in these two fields. The limitations of organic stationary phases at high temperatures and methods for assessing their performance are covered.

Three other important contributions are concerned with an ingenious application of Doering's methylene insertion reaction to provide retention data for unavailable hydrocarbons, the use of transition metal complexes to separate unsaturated compounds and a demonstration of the feasibility of using clathrate complexes for separations according to molecular shape.

An interesting account of work in the U.S.S.R., mainly on gas–solid chromatography, by A. A. Zhukhovitsky, opens the last section on applications. These cover a very wide range from the separation of metal halides to anæsthetic research.

As with previous proceedings in these series, the book is well produced, and the editor is to be congratulated on its early publication and particularly for making the considerable effort to include an author- and subject-index. The steady increase in the cost of these volumes is regrettable.

The third compilation in the series, *Gas Chromatography Abstracts*, maintains well the high standard previously achieved. The volume contains 875 abstracts of papers which appeared in 1959 and the early part of 1960. The abstracts are usually short and compact, but quite adequate in most cases to decide what papers in the rapidly expanded literature on the technique are worth a more detailed study. By far the most valuable feature of these volumes, however, is the elaborate index which enables references on even the most obscure subject to be found if they exist.

The editor and his abstractors are to be congratulated for continuing to provide so consistently such an excellent service for all those interested in gas chromatography and its application.

Gas Chromatography[4], by Ernst Bayer, is an extremely useful laboratory hand-book for all those engaged in working with this fascinating technique. It seems to strike just the right balance between essential historical and theoretical background and the practical aspects with which it is, of necessity, largely concerned. The author is obviously one of the small number of enthusiasts who embraced the technique in its early stages and has since turned his hand to most of the new developments as they appeared. This outlook has, however, led him to cram too much material into too few pages, and although this is seldom confusing, the treatment of many topics is so brief that it often becomes irritating.

There is a wealth of information on almost every significant form of apparatus which has been used, but perhaps the most valuable section is that dealing with a wide range of practical applications. Small errors, many of which seem to spring from the translation, are fairly frequent; for example, on p. 37 the method of coating capillary column is vague if not misleading, and on p. 55 the term "ionization potential" is incorrectly used. These do not, however, seriously detract from the usefulness of the book as a handy source of information in the laboratory. Newcomers to the technique faced with the problem of getting on with the job as soon as possible will find it invaluable, but even the old hands will find it useful to have on the shelf.

Dr. D. Ambrose and Barbara A. Ambrose have prepared a volume[5] that is an interesting contrast to Bayer's book. The authors have set out to provide a compact balanced primer for the beginner, and to this end they have carefully selected the essential features of the techniques and discussed them with just sufficient material to make the treatment clear but not confusing. For this reason the book is interesting to read at a sitting in contrast to Bayer's book, which is best used to throw some light on a particular problem when it arises.

The chapters on separation and selective solubility, and qualitative and quantitative analysis are particularly good, but on the apparatus side it is a little disappointing that more emphasis has not been given to capillary columns and ionization detector, two of the more important recent developments. The text has not been cluttered by references to all the relevant papers, but a list of suggested items for further reading is included at the end of each chapter. It is a happy thought to include as appendixes a guide to the choice of commercial equipment and a list of addresses of manufacturers of complete instruments and ancillary apparatus.

The book is well produced with very clear diagrams, and its moderate price should encourage its appearance on the bookshelves of most laboratories in addition to its obvious place in chemical libraries.

Theoretische Grundlagen der Gas Chromatographie[6], by Von Géza Schay, is at present available only in German and therefore will be of restricted interest. Prof. Schay has attempted to fill a notable gap in the literature of gas chromatography by standing back, after the initial period of hectic development has subsided, in order to take a fresh look at the technique and in particular the basic physical chemistry on which it rests.

Not unexpectedly, there is a pronounced bias for gas–solid interactions and the gas chromatographic techniques which take advantage of such adsorption. The treatment of adsorption isotherms and the frontal analysis, displacement and chromothermographic procedures is excellent and will be stimulating to many workers in Britain less familiar with developments in gas–solid chromatography. On the other hand, the chapters dealing with the elution techniques on gas–liquid chromatography are less impressive, and the sections on capillary columns and ionization detectors are somewhat disappointing. An assortment of applications is given in the last chapter, but these seem out of place in a book of this type and could well be omitted in favour of an expansion of the chapters on gas–liquid chromatography and general techniques if an English edition is contemplated.

D. H. Desty

Gas Chromatography Discussion Group

THE annual general meeting of the Gas Chromatography Discussion Group of the Institute of Petroleum Hydrocarbon Research Group was held in the Glazebrook Hall of the National Physical Laboratory on March 16 and was followed by an informal symposium attended by about two hundred members and guests. The report of the Committee for the past year records that the membership of the Group is now approaching five hundred, and the weight of work which this growth has imposed on the honorary officers has led the Committee to look favourably on an offer by the Institute of Petroleum to assume responsibility for a large part of the routine administration of the Group. On the recommendation of the Committee the meeting agreed that this offer should be accepted. Besides the two informal symposia, and preparations for the international meeting in Hamburg, the main activity of the Group during the past year has been the preparation of *Gas Chromatography Abstracts*, which is distributed quarterly to members; the bound volume for 1960 has been available for some time and that for 1961 will be published shortly.

Introducing the informal symposium which followed, Dr. J. S. Anderson, director of the National Chemical Laboratory, welcomed the meeting to Teddington and made some monitory remarks on the organization of scientific societies. In the first paper Dr. G. A. P. Tuey gave details of the improvements made in the preparative apparatus described at the Amsterdam symposium by Atkinson and himself. Metal columns had been substituted for the glass ones used originally, since the use of an all-metal apparatus made the elimination of leaks easier; Ermeto compression type joints had proved satisfactory. The 1-m. by 1-in. diameter columns were joined by capillary U-tubes which served the same purpose as the mixing washers recommended by Golay for use in large columns. A katharometer designed for analytical use had proved unsuitable as a detector because of the peak reversal which occurred at high flow-rates; attempts to pass part only of the effluent through the katharometer were also unsatisfactory because the proportioning did not remain constant for all peaks, and in addition the throttle was liable to cause condensation of vapour as a result of adiabatic cooling and consequently an unsteady base-line. The best form of katharometer for this application was one with transverse sensing wires able to accept the total gas flow, such as had been used in the University of Birmingham. It appears from various authors that, with appropriate sample size, an H.E.T.P. of 3–5 mm. may be obtained in columns up to 50-mm. diameter. Recent work on H.E.T.P. as a function of flow-rate in these preparative columns somewhat surprisingly yielded S-shaped curves, of which one limb tended towards the origin at low rates of flow, in place of the normal U-shape. When the results were used to compare the parameters H.E.T.P., Resolution and S (suggested by Purnell), the last was found to be independent of sample size and was therefore considered a better parameter than the other two for characterizing a column. In discussion Dr. H. Boer and Mr. D. H. Desty emphasized the value of the cross-section detector in preparative work because it had a linear response up to almost 100 per cent vapour. In reply to a question, Dr. Tuey stated that the highest sample recovery was obtained by scrubbing the gas with a solvent or a reagent; an electrostatic precipitator was liable to cause chemical change.

Dr. J. N. A. Ridyard discussed the linearity and response of the flame ionization detector. The upper limit of linearity is generally given as 10^{-8} amp., corresponding to a mean flow of about 2 μgm./sec. for a 1-mgm. sample on an ordinary analytical packed column. Ridyard investigated the effect of varying the operating conditions and used a computer to derive contour maps of the response at 1 and 10 per cent non-linearity as functions of the hydrogen and nitrogen flow-rates, the height of the probe above the jet and the diameter of the jet. There was generally an optimum position for the probe and a longer linear range was obtained if the probe was negative with respect to the jet. There were optimum rates of flow of both hydrogen and nitrogen, and this last point was confirmed in discussion by Dr. R. Kaiser.

Dr. E. Heine described the use of packed capillary columns, an interesting innovation in technique which is suitable for the separation of low-boiling hydrocarbons. The columns are made of glass drawn out in the usual way in the machine described by Desty. The tubing (2-mm. internal diameter) which is used, however, has first a clean wire 1-mm. diameter placed in it centrally and the annular space is then packed with powdered adsorbent (alumina, 0·1–0·15-mm. diameter, prepared by baking at 400° C. for 9 hr.) so that as the column is drawn the adsorbent moves with the glass and sticks to the inner wall of the capillary, which is about 0·3 mm. in diameter. Before use the column is flushed with dry hydrogen for a day at 120°. Heine showed chromatograms of high-speed separations of gaseous mixtures which he had obtained on these columns; in one example, obtained on a 2-m. column at 90° C., complete separation of the ethane/ethylene and propane/propylene peaks had been obtained; in another, 15 saturated and unsaturated hydrocarbons up to C_4 had been separated at 80° C. The method of aqueous deactivation to adjust selectivity, suggested by C. G. Scott, could be used with these columns; if carrier gas containing a suitable concentration of water was passed into the column, equilibrium was reached in a few hours. On close examination irregularities in the packing were obvious, but despite this the column performance was good, presumably because the sequence of narrow gas passages and empty spaces between the grains allowed quick mass transfer between the phases. In discussion Mr. C. G. Scott commented that he had tried to make similar columns but found them too fragile because of the strains set up in the glass by the adhering particles of alumina; there is evidently some know-how in question here which remained unexplained to the meeting. Dr. A. Goldup spoke as a protagonist of liquid-coated capillaries and showed a chromatogram obtained on a 2-m. column, 0·002 in. diameter, coated with squalane, in which a gaseous mixture, similar to one quoted by Heine, had been separated in 5 sec. Mr. D. H. Desty mentioned his attempt to make a regularly packed capillary column by drawing and twisting wire.

Dr. T. R. Phillips, in describing the separation and analysis of the isotopes of hydrogen, directed attention to the possibility that the displacement technique might yet find a use in modern gas chromatography, since the method offers the advantages of greater capacity for a given-sized column and that the sample is not contaminated by carrier gas. This last statement appears somewhat paradoxical because it is generally put in the opposite sense in favour of elution chromatography. It may, however, be justifiable in respect of preparative gas chromatography since in this technique one of the grestest problems has been the separation of vapours at low partial pressures from large amounts of carrier gas, and it may be advantageous to avoid the use of a carrier in some circumstances. Phillips has separated hydrogen and deuterium on columns containing molecular sieve 5 Å. in a method which is effectively one of self-displacement. The order of elution is first hydrogen, second deuterium (the opposite to that obtained by Glueckauf and Kitt in their separations on palladium black) and the method is useful for removing small quantities of hydrogen from deuterium-rich mixtures. Up to 300 ml. of sample was passed into the column cooled in liquid nitrogen; the Dewar vessel containing the liquid nitrogen was gradually lowered and the sample itself displaced the hydrogen, which was then followed by the deuterium. At the end of each run the column was filled with deuterium and there was no need to remove this before admitting the next sample; there was thus no need for evacuation of the column or for a carrier gas. Tests showed that molecular sieve had no tendency to promote the formation of HD molecules.

Dr. P. G. Jeffery described the application of gas chromatography to the analysis of gases obtained from rocks and minerals. The rocks he had examined were mostly silicates and these yielded small quantities of carbon dioxide when boiled with dilute phosphoric acid. The reaction had been carried out in a 10-ml. flask on powdered samples of up to 1 gm., and the gas evolved was analysed on columns containing silica gel or activated carbon. The method enabled concentrations as low as 5 p.p.m. to be determined, or, on the other hand, enabled analyses to be made on very small samples, as, for example, when rocks had been hand-sorted under the microscope, if the concentrations were higher. The same method had been used for determining the carbon dioxide content and nitrous oxide content of monoethanolamine solutions. Attempts were also being made to determine the water which is present to the extent of 2–20 per cent in most rocks, either on the surface of the mineral grains, chemically combined, or as hydroxyl ions held by weak forces between the layers of minerals with sheet structures. The water was driven off by fusing the sample in a silica tube with a suitable flux (for example. a 50/50 mixture of sodium tungstate and borax glass) at temperatures up to 700° C. In early experiments the water had been allowed to react with calcium carbide, but later it was found more satisfactory to determine it directly on a polyethylene glycol column. The method was calibrated by using samples of rocks containing known concentrations of water; in fact it had proved difficult to ensure the liberation of all the water from the samples and there were side reactions which removed water. Other gases, for example, helium from pitchblende, had also been determined by heating rock samples, and in this way hydrogen, helium, argon, oxygen, nitrogen and carbon monoxide had all been obtained from silicate rocks. The volume of the gases was greater than the free space and their presence could only be accounted for by some kind of adsorption. The novelty of this application of gas chromatography aroused considerable interest and many in the audience were intrigued by Jeffery's claim to have found hydrocarbons (even though only to the extent of a few p.p.m.) in granite.

The last paper of the meeting was given by Dr. R. P. W. Scott on resistance to mass transfer in capillary columns. Golay derived an expression for H.E.T.P. in terms of solute and column parameters, but experimentally it has been found that values of H.E.T.P. are significantly higher than those given by the equation Khan suggested a theory to explain the difference in which he postulated another effect, the interfacial resistance to mass transfer. Scott had tried to determine the reality of this effect; the experiments and their mathematical analysis were designed to distinguish between the effects of all the factors taken account of in the Golay equation. A column consisting of 100 ft. of nylon capillary 0·020-in. diameter was used, and H.E.T.P.'s were determined at different film thicknesses (from zero upwards) and gas velocities for samples of n-heptane on dinonyl phthalate with argon as carrier gas. In this system Khan's factor was not found to be significant, but it might well be when a more polar solute is in question What did appear to be a significant cause of departures from the Golay equation was a factor associated with the wall of the column, presumably adsorption.

D. AMBROSE

VEB CARL ZEISS, JENA

GOLDEN JUBILEE OF WORK ON AIDS TO VISION

FOLLOWING a long period of scientific preparatory work the Zeiss Works at Jena organized, fifty years ago, the 'Ophthalmo'-Department and began the manufacture of ophthalmic lenses, including specific types of aids to vision as well as ophthalmological instruments.

This article reviews the development of that Department during the past five decades and the considerable extent to which Jena instruments and aids to vision were able to share in the world's progress in ophthalmology and in the sphere of ophthalmic optics.

Despite their manifold drawbacks, the flat forms of spectacle lenses—bounded by like surfaces on both sides—actually retained that form for more than a period of six hundred years; and this in face of the fact that meniscus-shaped lenses were suggested as early as in the eighteenth century and that time and again after 1800, W. H. Wollaston and L. J. Schleiermacher in 1842 directed attention to the theoretical importance of rotation of the eye. A few firms produced plano-lenses and, in a few instances, even meniscus lenses on the strength of empirical experiments and, for the correction of astigmatic eyes, spectacle lenses with toric surfaces. However, mercenary motives proved strong enough to override any of these beneficial suggestions, thus permitting the inefficient equilateral lenses and cylinder lenses to hold their own.

Ernst Abbe, who himself wore spectacles with equilateral lenses, was very dissatisfied with this state of affairs concerning spectacle lenses. Yet, overburdened with other Zeiss problems, his illness and early death prevented him from devoting his full attention to the solution of the problem.

Moritz von Rohr, shortly after Abbe's death, energetically occupied himself with the problem. Aided by the suggestive and advisory assistance of Allvar Gullstrand, the Swedish ophthalmologist and Nobel Prize winner, known for his outstanding mathematical and optical talents, this work was considerably promoted. M. von Rohr, H. Boegehold and A. Sonnefeld provided the geometro-optical preliminaries for starting the production of the well-known 'Punktal' lenses of Carl Zeiss, Jena, and other aids to vision associated with them, including Katral lenses, telescopic spectacles, etc. (Although now retired, H. Boegehold and A. Sonnefeld are still active with the Jena Zeiss Works in a scientifically advisory capacity.)

The new point-focal depicting Zeiss spectacle lenses were for the first time put on the market on April 1, 1912. Unparalleled, the Zeiss 'Punktal' lens found open markets thenceforth throughout the world and earned the unqualified recognition of opticians and spectacle wearers. From that time on, often despite considerable visual afflictions, the 'Punktal' lenses afforded visual relief and improved vision to millions of people by helping to restore former working capacity up to old age. Rational and optically highly developed production methods initiated by R. Lincke provided a guarantee that, even on large-scale production, spectacle wearers could be sure of obtaining first-choice Zeiss spectacle lenses of an invariably high quality.

The Jena Zeiss Works also carried out pioneer work on spectacle frames ('Perivist' spectacles) and of specific types of visual aids (telescopic spectacles, reflector spectacles, contact lenses). After 1945, the Jena firm furthermore succeeded in crystallizing the scientific work on the aids to vision by the production of spectacles for kyphotic wearers, of 'Isopal' lenses, anterior-chamber lenses, corneal contact shells, etc. Work is thus still being carried out towards providing the spectacle-wearing public with still better and perfect aids.

Within the same fifty-year period (also as a result of Gullstrand's suggestions and of his co-operation with M. von Rohr), ophthalmologists were provided with new instruments, under the supervision first of O. Henker and, later on, of H. Hartinger and F. Fertsch. The new instruments rapidly became internationally recognized and elicited many professional suggestions, which again resulted in the establishment of close contacts with eminent ophthalmologists throughout the world and in the design, as a consequence, of other new instruments for professional purposes. The 'Gullstrand' slit-lamp, built and progressively modernized in Jena, may be said to represent an indispensable asset in any ophthalmological consulting room. Further instruments which originated in the Jena Zeiss Works include the following: 'Vertex' refractionometer for measuring the refractive power of spectacle lenses; retinal camera, for the photographic reproduction of the fundus oculi; projection perimeter, for examining the visual field ; coincidence refractionometer, for measuring imperfections in the refractive powers of the eye.

While in pre-war times Zeiss ophthalmological instruments held what may be claimed to be a monopoly in the world's markets, new production centres sprung up in many other countries afterwards and afforded to the Zeiss Works an opportunity of proving the worth of their instruments in sound competition. VEB Carl Zeiss, Jena, as a consequence, set up a production programme which practically covers the whole latitude of this particular class of instruments. In pursuance of this programme the Jena firm also developed the new retinal camera 'Retinophot', which permitted the colour-photographic reproduction of the fundus oculi, as well as the Hartinger coincidence refractionometer for measuring imperfections in the refractive powers of the eye, and the Hartinger recording adaptometer for determining the quantitative curve of dark-adaptation. The excellent performance of these instruments resulted in a considerable increase of production and exports to practically all countries in the world. Progressive research and development work justifies the hope that the VEB Carl Zeiss, Jena, will continue to contribute effectively towards the improvement of vision and will efficiently assist ophthalmologists and the optical trade in fighting eye diseases and visual defects.

The June number of the *Jena Review* will publish special articles concerning the fifty-year history of Jena aids to vision and ophthalmological instruments.

AUGUST SONNEFELD

SCIENTISTS IN GOVERNMENT SERVICE

THE ninety-fifth report of the Civil Service Commissioners covers the period April 1, 1960, to December 31, 1961, and future reports will cover the calendar instead of the financial year*.

Much of the detailed information has been relegated to statistical tables which in the present report cover both 1960 and 1961. Recruitment to the administrative class of the Home Service and the senior branch of the Foreign Service is regarded as being specially encouraging: since 1955–56 the numbers of candidates competing and of recruits appointed, especially by Method II, have been rising, and, in 1961, 447 candidates competed by this method, of whom 38 were successful for the administrative class and 27 for the Foreign Service; the indications are that this will continue to be the more popular method. During the period the upper age-limit for candidates in the normal competitions for the administrative group of appointments was raised from 24 to 28, and the Commissioners, in conjunction with the Treasury, have reviewed the means of publicity used in the modern universities to bring Civil Service posts to the notice of students of good quality. Besides continuing to give serious consideration to the problem of attracting more competitors from universities other than Oxford and Cambridge, the Commissioners have given much thought to the nature of the examinations and administrative tests used for selecting candidates for the higher classes of the Service, but for the majority of candidates a general written examination still seems to be the most objective test of intellectual powers and capacity for self-expression, and, in conjunction with their records, the fairest way of selecting for interviews and group tests.

---

* Report of Her Majesty's Civil Service Commissioners for the period 1st April, 1960, to 31st December, 1961. Pp. v+50. (Ninety-fifth Report.) (London: H.M.S.O., 1962.) 4s. net.

On the scientific and engineering classes, the Commissioners comment on the distribution of successful candidates among the older and the newer universities and over different parts of the United Kingdom, no university having a share greatly out of proportion to its numbers. While the Commissioners appear to have only moderate success in filling established posts which are notified to them, many of these posts are, in fact, occupied by people in a temporary capacity. This is not a disadvantage to the Scientific Civil Service, as the Zuckerman Report noted, and it is often preferred by the scientist. The recruitment of engineers appears to be less satisfactory although a small number of very good candidates has obtained professional qualifications through departmental student apprenticeship and other schemes. It must be several years before this source contributes significantly to the strength of the professional engineering class and meanwhile in the Works Group, including architects and surveyors, a large proportion of the basic grade vacancies remains unfilled. However, most of the vacancies for posts in grades above the basic level have been filled satisfactorily from competition.

Encouraging results were obtained following the decision to hold separate competitions for scientific staff for the Patent Office, 59 out of 75 declared vacancies being filled by this means in 1961.

Since June 1960 some of the larger departments have had authority to recruit up to half their entitlement of Research Fellows directly, and of 96 Research Fellows recruited in 1960 and 1961, 18 were appointed through departments. During 1961, 10 permanent appointments were made to the scientific officer class through the Interviewing Board, acting jointly for the Civil Service Commission and the Atomic Energy Authority, which visited Canada and the United States to see British scientists who desired to return to the United Kingdom, and 9 Research Fellows were also appointed.

BRITISH UNIVERSITIES DURING 1957–61

UNIVERSITY GRANTS COMMITTEE INTERIM REPORT*

ALTHOUGH the interim report of the University Grants Committee on University Development in the years 1957–61* was published five weeks after the Chief Secretary to the Treasury made his statement on March 14 regarding the recurrent grants for the next quinquennium, it may be assumed that the contents of this report were available to the Government when its decision was taken, and the Committee indeed expresses the hope that the record will be of assistance in considering the provision to be made for the quinquennium 1962–67. The present quinquennium has been one of increasingly rapid development in the universities: student numbers rose by 20 per cent in 1956–61 compared with 2 per cent in 1951–56, and staff by 18·4 per cent. Although total university expenditure rose by 61 per cent compared with 46 per cent and recurrent Treasury grants by 72 per cent, from £28·2 million in 1956–57 to £48·4 million in 1960–61, and non-recurrent grants from £9·1 million to £22·1 million, or 143 per cent, the universities have not been able to achieve all that was hoped for when the grants for the quinquennium were announced in 1957. Besides relatively greater expansion in the pure and applied sciences and in research, the continued decline in the value of money has been an important factor. Building programmes have steadily increased in size since 1957, and although supplementary recurrent grants for the last three years of the quinquennium were approved in 1959 and other supplementary grants to cover the cost of increases in academic salaries in 1957 and 1960 the strain on university finances has been great.

At the beginning of the quinquennium, the Committee's grant list included 21 universities and 3 university colleges; to these the University of Sussex, which first appeared in the grant list in 1960–61, has been added, and the University College of North Staffordshire is applying for a Royal Charter as a university, while authority has been given for the establishment of six more universities. By October 1961 the number of students had grown from 50,000 in 1938–39 and 100,000 in 1958–59 to 111,385 compared with the 102,000 visualized at the time of the quinquennial settlement. Omitting the University of London, with 22,574 full-time students, the Universities of Oxford and Cambridge with 8,800 and 8,934, respectively, and counting separately the two divisions of Durham, the five constituent colleges of the University of Wales, and St. David's College, Lampeter, at October 1961, three of these institutions had less than 500 full-time students; one, 500–999; one, 1,000–1,499; ten, 1,500–1,999; four, 2,000–2,999; three, 3,000–3,999; two, 4,000–4,999; and four, 5,000 and more. Of the 31,671 students entering for the first time in 1961–62, 8,433 were in science, 5,118 in applied science, 2,530 in medicine, 663 in dentistry, 560 in agriculture, and 255 in veterinary science; for 1956–57 the corresponding figures were 5,888; 3,842; 2,441; 692; 562; and 227, respectively. For the distribution of all full-time students by faculties the corresponding percentages were 25·2; 15·2; 11·2; 2·7; 1·8; and 1·1 in 1961; and 22·2; 13·9; 14·4; 3·0; 2·1; and 1·3 in 1956–57, respectively. The Committee is basing its authorizations for building plans on the assumption that this tendency will continue and that two-thirds of the increase in student numbers in the coming years will be in pure and applied science.

Once again the Committee reports that generally the proportion of outstandingly good and outstandingly weak students remained lower, while that of good second-class students was higher than it was before the War. A further inquiry in 1958–59 into the success or failure of students who entered universities in October 1955 to study arts, pure science, applied science or agriculture and forestry showed that the proportion who left without success on account of academic failure was 9·9 per cent, compared with 11·3 per cent in a similar study for October 1952. The proportion of full-time advanced students continued to increase: in 1960–61 they numbered 17,836 compared with 13,379 in 1956–57, and the proportion of higher degrees to first degrees in pure science was 21·4 per cent, and in applied science 19·6 per cent. Of 11,608 (or 10·8 per cent) full-time students taking courses of a year's duration or longer in 1960–61 coming from homes outside the United Kingdom (compared with 9,907 in 1956–57 and 5,213 in 1938–39) about 60 per cent came from within the Commonwealth, while the British Post-graduate Medical Federation had a further 2,013 students from overseas out of 2,994 taking courses of less than a year.

---

* University Grants Committee. University Development: Interim Report on the years 1957 to 1961. Pp. 28. (Cmd. 1691.) (London H.M.S.O., 1962.) 1*s*. 6*d* net

There has been little change in the proportion of full-time students who live in colleges or halls of residence; although the numbers increased, from 24,652 in 1956–57 to 29,474 in 1960–61, the percentage remained 27·4. On the other hand, both the numbers living in lodgings, and the percentage, increased: from 41,291 in 1956–57 (46·0 per cent) to 54,614 (50·7 per cent) in 1960–61. Moreover, the University Grants Committee points out that the supply of lodgings for university students is becoming exhausted and in some places is likely to contract. The position varies widely, and in 1960–61, 53·4 per cent of full-time students at Cambridge and Oxford lived in colleges or halls of residence and only 1·9 per cent at home; for Scotland, the corresponding figures were 12·4 and 49·3, and for London, 18·3 and 27·9; for other institutions in England and Wales they were 27·6 and 17·2. Nor do these figures indicate the full extent of the variations, from the University College of North Staffordshire, where virtually all students are residential to Birmingham, or the Manchester College of Science and Technology, where almost all students live in lodgings or at home. Lack of capital admittedly has so far prevented the building of more halls of residence, but the University Grants Committee has already pledged fullest possible support for more ample provision for halls of residence in the coming quinquennium.

On academic staff this report merely records an increase in full-time personnel in teaching departments from 10,485 in 1956–57 to 12,921 in the autumn term, 1961; for professors, the corresponding figures are 1,459 and 1,684; for readers, assistant professors and independent lecturers, 757 and 926; for senior lecturers, 4,903 and 1,604; for lecturers, 4,903 and 5,959; and for assistant lecturers and demonstrators, 1,176 and 1.559. These figures do not, however, include staff of the rank of senior lecturer or below at Oxford and Cambridge. The report gives the rates of academic salary current in 1954, 1957 and 1960, but makes no comment beyond indicating that further proposals were submitted to the Chancellor of the Exchequer in July 1961 and that the Chancellor approved a recommendation for revision of the existing scheme for supplementing superannuation benefits which came into effect on April 1, 1960. Incidentally, in a written answer in the House of Commons on April 19, Mr. H. Brooke estimated the cost of the new scales for lecturers and assistant lecturers under the 3 per cent increase in the total salary bill for university teachers at about £1 million a year. At the same time he repeated his view that the university financial position should be reviewed in about two years time.

On income and expenditure generally, the report records an increase in the aggregate income of the universities from £41·656 million in 1956–57 to £67·467 million in 1960–61, of which 69·8 per cent and 72·7 per cent, respectively, was from Parliamentary Grants; 10·8 per cent and 9·4 per cent from fees; 4·0 and 2·8 per cent from endowments; 3·1 per cent and 2·0 per cent from grants from local authorities; 6·5 per cent and 8·9 per cent from payments for research; and 1·2 per cent and 0·6 per cent from donations and subscriptions. Earmarked grants presented a minor feature in the quinquennium, but rose from £11,000 in 1959–60 to £39,230 in 1960–61 and £36,250 in 1961–62; of the latter figure, £8,000 is a contribution to the Institute of Criminology, Cambridge; £12,000 for postgraduate courses in radiobiology at Birmingham; £8,000 for postgraduate courses in conservation studies at University College, London; £4,000 for developments in management studies at Bristol (with a further £1,250 for developments at Cambridge); and £3,000 for postgraduate courses for youth leaders at Manchester. Proposals for increased fees were put to the universities which have proved generally acceptable and will take effect in 1962–63.

Expenditure rose from £41·841 million in 1956–57 to £67·163 million in 1960–61. Of this, administration represented 7·0 per cent and 6·7 per cent, respectively; for salaries and superannuation of teaching staff the corresponding figures are 43·2 and 44·2, respectively; for departmental wages (technicians and laboratory assistants) 11·4 and 11·4; for departmental and laboratory maintenance, 13·1 and 13·8; for repairs and maintenance of buildings, 6·3 and 3·1; and for rates, insurance, heat, light, water, porters' wages, 6·5 and 9·8. Special reference is made to rates, discussion of which was necessitated both by the decision to exclude universities and colleges in receipt of Exchequer grant from the mandatory relief of 50 per cent recommended by the Pritchard Committee and which was given effect by the Rating and Valuation Act, 1961, and also by the uncertainty as to the basis on which university property should be valued. The report does not refer in detail to the test cases which have been proceeding but merely notes the decision that the universities should be reimbursed for their expenditure on rates during the next quinquennium (estimated at £1·5 million in 1961–62) by earmarked grants.

Of the non-recurrent grants totalling £92·363 million for the four years 1957–58 to 1960–61, £69 million was approved for buildings and professional fees, £18·7 million for furniture and equipment and £4 65 million for sites and properties, the actual expenditure for these purposes being £54 million, £10·8 million and £4·7 million, respectively. Of the total, 7 per cent was for buildings associated with arts subjects, 62 per cent for buildings for pure and applied science and 31 per cent for general service buildings such as libraries, student unions, refectories, halls of residence and the like. A major departure from the normal practice of recommending grants only for the initial furnishing and equipping of new accommodation has been in the authorization of provision of about £2 million over a period of years towards the cost of new electronic computers. With the contributions the universities themselves will make, this will ensure that in due course practically all universities will have their own computers and the one or two others will have access to computers. Besides the action taken in accordance with the recommendations of the Gater Committee and of Sir Arthur Rucker, the University Grants Committee has suggested to universities standards of accommodation of various types on which they can base their applications for grants for new accommodation, and has adopted new methods, based on cost analyses, of assessing grants for halls of residence and for science buildings, which encourage economy and flexibility. Finally, the Committee refers to the new arrangements put into effect as a result of criticism from the Public Accounts Committee, under which the Comptroller and Auditor General has full access to the records maintained by the Treasury for their control purposes. These arrangements were considered by the Committee of Public Accounts for the Session 1960–61 to have worked satisfactorily and the Committee recommended they should remain in force.

DIAMONDS CONTAINING CONTROLLABLE IMPURITY CONCENTRATIONS

By C. M. HUGGINS and P. CANNON

General Electric Research Laboratory, Schenectady, New York

THE presence of considerable quantities of impurities in natural diamond has recently been confirmed[1,2]. This led Frank[3] to remark that multiple techniques of examination must be used on such material. In view of the report of Yoneda[4] concerning possible effects of nitrogen on the X-ray diffraction patterns of diamond, it seems worthwhile to us to comment further on some of the results which we have gained by the deliberate introduction of a given impurity into laboratory-grown diamond. We shall limit ourselves to a qualitative examination of the electron spin resonance spectra of a few specimens, in the belief that the profundity of the effects suffices to establish that progress in this area is now limited by the composition variability of natural diamond.

Samples of diamond were prepared in the following way. A uniaxial press system[5] was used in conjunction with an indirectly heated sample holder[6]. The reaction space was filled with extruded rods of spectrographic graphite powder mixed with the powdered transition metal catalyst. The static pressure applied during extrusion was 500 lb./in.^{2}. The impurity to be introduced into the growing diamond was present either in elemental form in the mix or as an alloy component with the transition metal. Thus, in the series of experiments reported here, pure nickel was used as the catalyst, and pure boron or aluminium powder was added in the requisite amount to the reaction mixture. All the materials used in the reactions were pre-fired in vacuum and cooled in argon. Cell assembly was carried out under dust-free conditions. Diamond was produced by subjecting these samples to pressures in the vicinity of 57 kb. and temperatures in the range 1,400°–1,600° C. (slightly different temperatures and pressures are utilized with the different catalyst compositions, since the equivalent alloys melt at different temperatures).

The product diamond was recovered by acid dissolution of the metal and residual graphite, followed by extensive washing. The crystals made using pure nickel consisted of attractive, light-green octahedra, whereas the aluminium-containing diamond was colourless (using a 33 atomic per cent aluminium in nickel mix) and the boron-containing material was a deep indigo (using a 5 atomic per cent boron in nickel mix). Both the boron- and aluminium-doped diamonds were electrical conductors. Resistivities were between 5×10^0 and 5×10^8 Ω-cm., depending on the conditions of preparation.

Doped diamond was also prepared by high-pressure, high-temperature diffusion of the doping elements into existing man-made diamond, both in the presence and absence of a transition metal catalyst. Lightly coloured or colourless conducting diamond was recovered from these experiments. The concentrations of boron and aluminium introduced by these techniques ranged up to 10^{21} atoms/c.c., as determined by chemical analysis, for example, by alkali titration of boron trioxide resulting from combustion.

Samples of these materials were examined by electron spin resonance spectroscopy. All v-mode, derivative spectra were obtained using a Varian Associates *V*-4500 ESR spectrometer, a *V*-4007 6 in. electromagnet, a *V*-4547 Multi-purpose cavity system and a Moseley *X–Y* recorder. Spectrometer frequency was maintained at 9152 ± 5 mc.p.s. (field calibration was obtained with *V*-4210*A* NMR spectrometer equipped with water sample). Low-temperature spectra were obtained by maintaining sample temperatures (measured with a thermocouple) to ± 2° C. in a flow of pre-cooled, dry nitrogen gas. Any possible radio-frequency saturation was checked by varying the klystron output over the available 20 decibel range, during which no changes in paramagnetic susceptibility or line contours were observed.

The electron spin resonance spectrum of our commercially available General Electric 'Man-Made' diamond 'RVG' (nickel-based) is shown in Fig. 1. There are two major features of interest: the broad band *a* (curve I) is typically that to be expected from transition metal impurities: we therefore assign it to nickel. The size of the absorption is consistent with the estimated concentration of nickel, namely $< \sim 10^{20}$ atoms/c.c. The detail *b* is shown on curve II with × 2 dispersion and × 5 amplification compared with curve I. The main structure of *b* appears to be

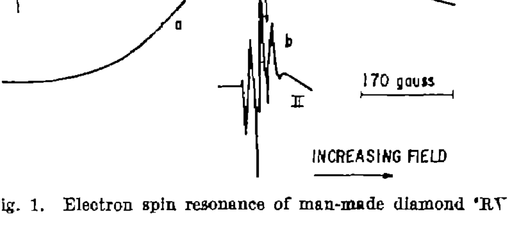

Fig. 1. Electron spin resonance of man-made diamond 'RVG'

a triplet, centred very close to a g-value (spin splitting factor) of 2·0: that is to say, whatever is producing b is behaving as though it possessed electrons of very nearly perfectly non-interacting spins with negligible spin-orbit coupling (it must be remembered that the specimen consists of many small crystals with random orientation in the sample tube).

Since weak fluorescence had been seen in this material, but not with nominally similar diamond of our Research Laboratory preparation, we examined the spectrum obtained from specimens in which the purity of the starting materials had been rigidly controlled. This showed the same major features as curve I; a specimen (3) consisting of material selected from their batch for its comparative clarity, showed less-developed resonance bands than that taken at random. Such triplets could conceivably arise from nuclear coupling with the two protons ($I = 1/2$) in $\cdot CH_2$, or nitrogen ($I = 1$). The second of these was already known to be a major impurity in natural diamond: the first was a possibility because residual hydrogen is known to cause poor diamond growth in the nickel system[7], or indeed to suppress growth completely if enough is present. Consequently, the radical $\cdot CH_2$ might be present in the crystals. Since some care had been taken to exclude hydrogen from the reactants, we considered the only possible source of hydrogen to be the water with which the sample holders[6] had been previously equilibrated. We therefore equilibrated six sample holders with deuterium oxide prior to preparing more diamond. The product from these runs, which was visually similar to the above specimens, was then examined by electron spin resonance. Once again the triplet detail (b) was seen. Had this previously been due to $\cdot CH_2$, we would have expected an expansion to a quintet due to the two deuterium atoms ($I = 1$) in $\cdot CD_2$. We therefore concluded the triplet b was due to substitutional nitrogen atoms in the diamond lattice. Further evidence was obtained by measuring the total width of the triplet (70 gauss) and the integrated intensity ratios of the lines (1 : 1 : 1). These values are consistent with the data of Smith, Sorokin, Gelles and Lasher[2]. Vacuum fusion analysis of a large sample of this diamond revealed a content of ~ 0·05 per cent nitrogen.

We next examined the diamonds prepared using an aluminium : 2 nickel catalyst (Fig. 3). The large wide band a in the nickel-based spectrum has disappeared (nickel–aluminium-based diamond is not strongly paramagnetic) and the detail at $g = 2·0$ is considerably reduced. Examination at higher gain showed that the latter was not exactly similar to the previous detail b, but poor signal-noise made it impossible to define the structure exactly. It seems likely that the detail is a highly suppressed nitrogen resonance. Some additional evidence in support of this view was obtained by examining nickel-based diamond into which aluminium had been introduced by high-pressure, high-temperature diffusion. The wide a band was lessened in conjunction with near extinction of the triplet b, indicating the considerable sensitivity of the nitrogen-atom resonance process to the presence of aluminium, or the loss of nitrogen from the crystal during incorporation of aluminium.

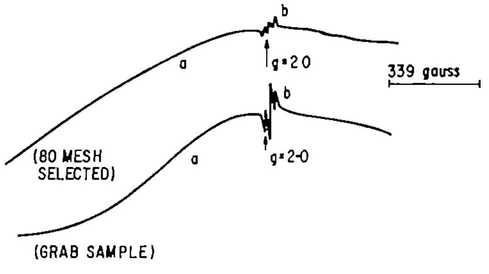

Fig. 2. Electron spin resonance of nickel-based diamond, laboratory preparation

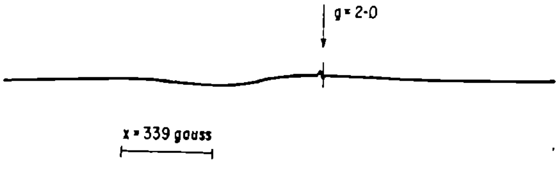

Fig. 3 Electron spin resonance of diamond from system using 2 nickel · aluminium catalyst

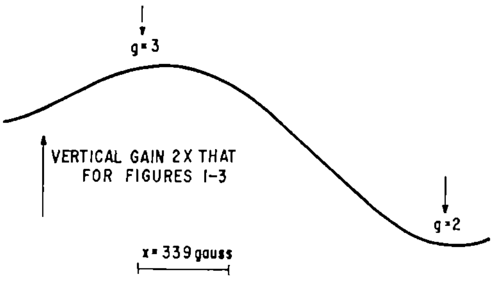

Fig. 4. Electron spin resonance of boron-doped diamond, growth-incorporated

Examination of boron-doped diamond (boron incorporated by growth) gave no sign of any absorption at $g = 2$ at room temperature, but a substantial broad resonance centred around $g \approx 3$ (Fig. 4). No hyperfine structure appeared when the specimen was cooled to 100° K., but the $g = 3$ band decreased in intensity, and a structure of unresolved detail began to appear at $g = 2$. We have no explanation to offer for these phenomena at present. It is apparent that the system is quite complex, since the nickel band is suppressed in these samples, but they are known to contain some nickel. Evidence for a nickel–boron electronic interaction was also derived from measurements on 'Man-Made' diamond into which boron had been introduced by diffusion. The spectrum was a horizontal straight line.

It is readily apparent from these results that differences of kind may be demonstrated in the electron spin resonance spectra of diamond by the introduction of quite small amounts of impurities. A careful examination of the X-ray parameters of these materials showed that there was no difference in the observed a_0 values down to the fourth decimal place. It is surprising that this should be so when up to 10^{21} impurity atoms/c.c. are present. In addition, diffraction spikes were seen in abundance only with those diamonds obtained from the 2 nickel : aluminium catalyst, in which nitrogen is presumably present only to a very small extent.

It seems to us, therefore, that not only are multiple techniques required in the examination of diamond, but also that it is necessary to have available specimens of known and reproducible composition.

RESOLVING POWER WITH TRITIUM AUTORADIOGRAPHS

By D. K. HILL

Postgraduate Medical School, London, W.12

THE penetrating power of β-particles from tritium is very low, and an autoradiographic image of a labelled structure to which the sensitive emulsion is applied therefore shows very little blurring due to spreading of the β-particles away from their source. The sharpness of the image has been calculated[1], but it was thought desirable to make a practical direct test with a radioactive source of known configuration.

'Araldite' epoxy resin, type *CY*212 (CIBA (A.R.L.), Ltd.) was made radioactive by combination with tritiated succinic acid. The reaction is similar to that taking place with dodecenyl succinic anhydride hardener (type 964*B*). The resin (2·7 gm.) was mixed with the ^{3}H-succinic acid (25 mc., 32·4 mgm.; Radiochemical Centre), and heated at 120° C. for 3 hr. The resin was then cured in the normal way, in gelatine capsules, with 964*B* hardener and 964*C* accelerator. The radioactivity of the product was 4,290 μc./gm. Its specific gravity was 1·12. The blocks were cut on a Huxley ultramicrotome (Cambridge Instrument Co.).

Two methods were used. In the first, a block of the radioactive 'Araldite' was cut to a smooth face on the microtome, and it was then re-embedded in non-radioactive 'Araldite'. The composite block was sectioned at right angles to the original face, and the sections, 0·75μ thick, were set up with Kodak '*A.R.*10' autoradiographic film. In these preparations a straight edge of radioactive material presented itself to the emulsion. After exposure for 165 hr. the autoradiographs were developed (Kodak '*D.*76', 5 min., 20° C.). The region of the radioactive straight edge was photographed under the microscope, and prints were made at a magnification of about 6,000. The spread was recorded by passing a narrow slit (240 mm. long, 0·1 mm. wide) over the print, by means of a micrometer, and measuring the amount of light transmitted from a lamp on one side of the slit to a photomultiplier on the other; the dark images of the silver grains caused a reduction of the light when they passed the slit. The average was taken for nine prints. The maximal grain density was about 400/100μ², and at this density there is appreciable loss of yield on account of 'over-hitting'; a correction was made for this. Each point on the record (Fig. 1) represents the contribution from several hundred grains. The spread of an autoradiographic image on either side of a narrow disk source is the differential of the curve in Fig. 1. The parameter which is chosen to characterize the spread is the width of the band, centred on the disk, which would contain 50 per cent of the whole grain count. This is equal to the width (Fig. 1) of the part of the observed record from 25 per cent to 75 per cent of the maximum. In this case it is 0·38μ. In emulsion '*A.R.*10' the grains are of diameter 0·2–0·4μ, and it is estimated that by pin-pointing the centres of the grain images the spread should be reduced from 0·38 to 0·34μ.

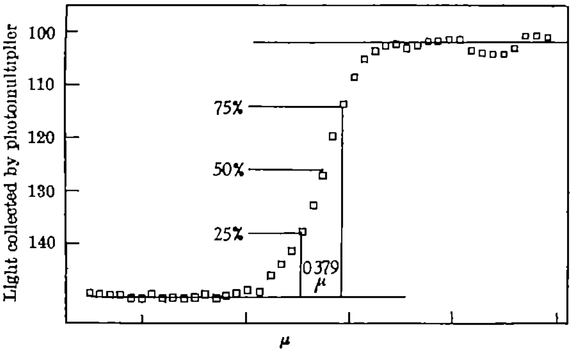

Fig. 1

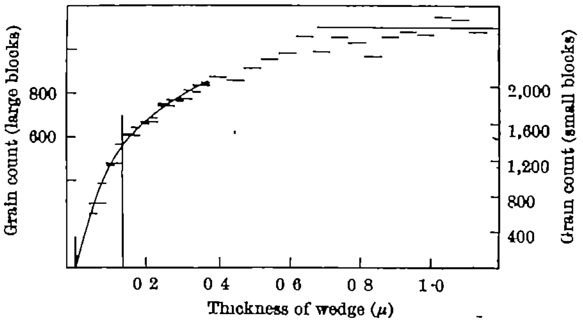

Fig 2

The second method was less direct in its approach. A face was cut on a block of the radioactive 'Araldite', and the angle of cutting was then altered by 0·5° so that subsequent sections were in the form of wedges, tapering in thickness. The autoradiographs, after times of exposure varying from 23 to 95 hr., were photographed, and the grain densities at varying distances from the tip of the wedge were counted on a number of prints. A correction was made for over-hitting. The extreme tip of the wedge breaks away during sectioning, and in Fig. 2 the curve is extrapolated beyond the region showing grain yield in the autoradiograph. The tip of the wedge appears to have broken away at a thickness of 0·031μ.

It is not difficult to prove that the form of this curve (Fig. 2) should be identical with that of each half of the symmetrical distribution over a thick section of a straight-edge source, as found in the first method. The solution for a disk source is therefore the differential with respect to the thickness of the wedge. The band containing 50 per cent of the total grain count from such a source is 0·226μ wide. This does not take account of the size of the grains and the corrected value for the band width, assuming pin-pointing of image centres of the grains, is found to be 0·24μ.

The discrepancy between the results by the two methods is possibly accounted for by inadequate allowance for grain size. This would mean an overestimate of the band-width by the first method and an underestimate in the second. If this is so, it may be concluded that a disk source will produce an image in which 50 per cent of the grains, when pin-pointed, lie in a band of width somewhere between the two estimates, 0·24–0·34μ; that is, 50 per cent of the grain centres lie within 0·12–0·17μ of the disk. By making use of the fact that the distribution is similar in form to a Gaussian probability curve it may be shown that the frequency of distribution descends to half its peak value at 0·21–0·30μ from the source. This is about the figure suggested earlier[1] on indirect data.

It should be noted that the results apply to sections of material which are thicker than about 0·5μ, that is, to sections in which self-absorption limits the contribution of deeper layers. Although the resolution could be improved by using extremely thin sections, it is generally not practicable with light microscopy to do so.

I thank Prof. A. F. Huxley and Dr. G. Winfield (CIBA (A.R.L.), Ltd.) for helpful discussion. This work was aided by a grant from Muscular Dystrophy Associations of America, Inc.

AN INTERNAL WAVE IN LAKE NYASA AND ITS PROBABLE SIGNIFICANCE IN THE NUTRIENT CYCLE

By D. H. ECCLES

Joint Fisheries Research Organization, Nkata Bay, Nyasaland

LAKE NYASA is extremely oligotrophic and shows very marked nutrient depletion above the thermocline which is formed about October[1-5]. In December it lies at about 20–40 m., but is driven down to about 150 m. by July and often breaks down in August. Despite these break-downs high nutrient-levels have never been recorded in the upper 40 m. There appears also to be a more permanent thermocline at about 200 m. (refs. 2 and 5) and the Lake probably represents a 3-layered system comparable with Lake Victoria[6]. Large short-term fluctuations in the level of the upper thermocline are well known at Nkata Bay[1-5] and have been interpreted as components of a uninodal seiche[2]. Series of temperature readings taken on voyages based on Nkata Bay have shown large displacements of this thermocline. In 1958 a difference of level of 30 m. was recorded between Nkata Bay and Mbamba Bay 70 km. to the north-east and intermediate stations showed a uniform gradient[3]. In December 1960 a large internal wave was observed in a voyage from Nkata Bay to Kota Kota returning up the other side of the Lake[5]. This wave was too short to represent a uninodal seiche.

During January–February 1961 a voyage was made from Nkata Bay to Fort Johnston and back. Series of temperature readings were made using a thermister thermometer, reading to 0·02° C., at the stations indicated in Fig. 1. Readings were taken every 5 or 10 m. in the region above the upper thermocline, but when this was approached the intervals were reduced to 2·5 m. and increased to 5 m. once it had been passed. The positions of isotherms at 0·2° C. intervals were obtained graphically from the results. The thermocline occurred in the region of the isotherms for 26°–27° C. and the area between these isotherms is plotted graphically in Fig. 2, which also shows the time and date of the readings. Considerable fluctuations in level were observed on the south-bound trip (Fig. 2*A*) between Nkata Bay and Monkey Bay with regular peaks at stations 2, 9 and 13 (possibly 5) separated by about 70 km. These were not so apparent in the northward trip (Fig. 2*B*), where fluctuations were less regular, although there is some indication of peaks at stations 23, 26–27 and 29. Unfortunately it was not possible to obtain any readings between stations 31 and 32 due to bad weather. The abrupt step between stations 7 and 8

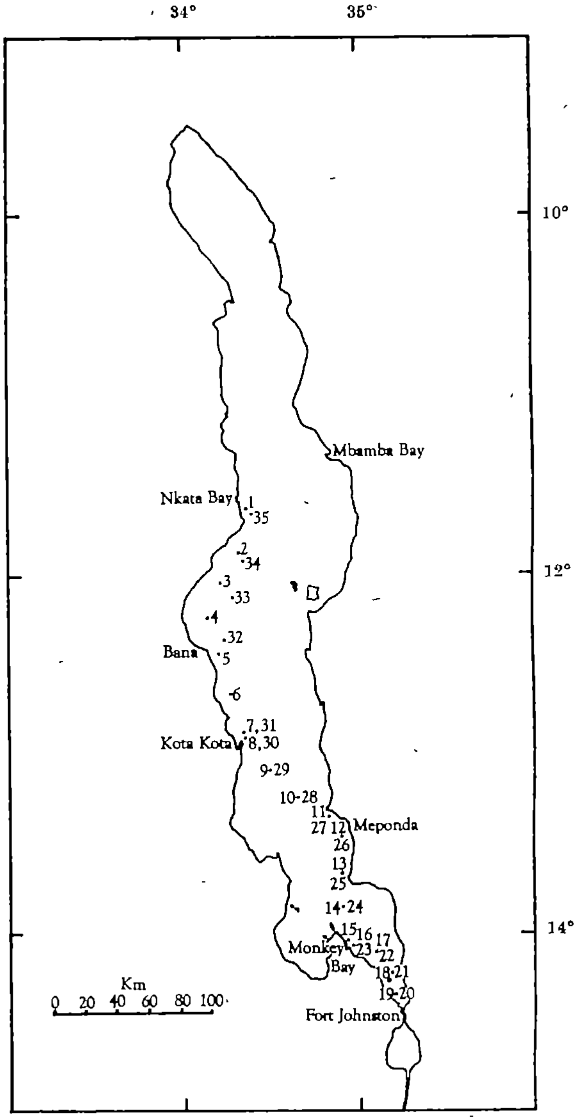

Fig. 1. Lake Nyasa showing positions of sampling stations

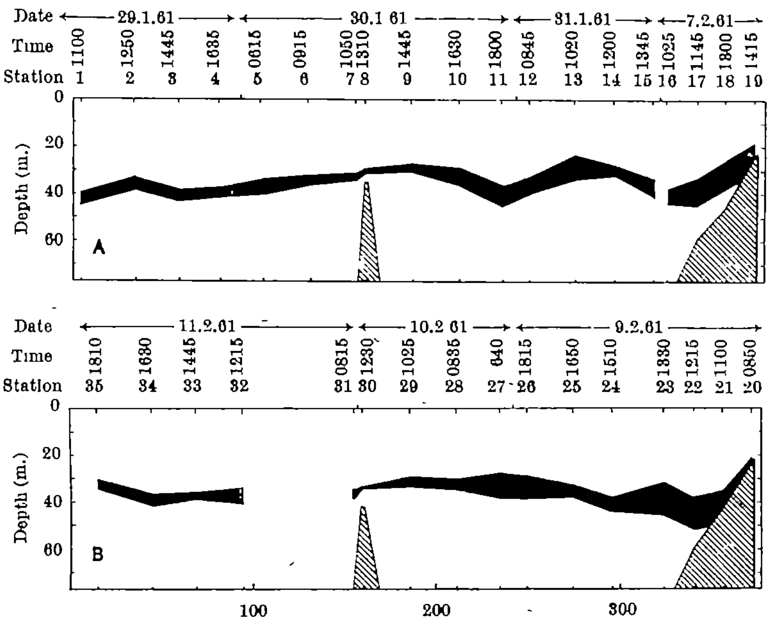

Fig. 2. The region between the isotherms for 26° and 27° C. in Lake Nyasa in January and February 1961. *A*, Southward voyage; *B*, northward voyage. Hatched areas indicate level of the Lake bottom

and 30 and 31 is undoubtedly the effect of a sand bar which extends from the end of the spit at Kota Kota. In the south-east arm, between Monkey Bay and Fort Johnston (Figs. 2*A* and *B*, stations 16–23), the amplitude of the fluctuations was increased and the isotherms became more widely spaced. In this region the thermocline meets the bottom, which rises gently to the south, and comparatively small changes in level of the thermocline must involve considerable horizontal displacements of water with resultant turbulence bringing about wider spacing of the isotherms. The extent of horizontal displacement can be judged from Fig. 2; on February 9 the isotherm for 26° C. met the bottom about 10 km. farther north than on February 7. Movements of this magnitude must also result in disturbance of the upper layers of the bottom deposits, and thus accelerate the release of the nutrients to the water.

The south-east arm of the Lake supports a much richer fishery than any other area[7,8] and it has long been considered by members of the Joint Fisheries Research Organization that this is partly due to tilting of the thermocline and upwelling of nutrient-rich water under the influence of the strong southerly winds that blow during May–August. Recent observations tend to support this view. The fertility of this area may also be influenced by the fact that annually the thermocline falls below 100 m., which is the maximum depth of the south-east arm, and nutrients can be returned directly to the epilimnion while some parts of the area are so shallow that the bottom never falls below the thermocline and nutrients are not lost. The internal waves described here suggest a further mechanism whereby the fertility of the south-east arm is maintained, and this is operative at the period when the thermocline is most marked and winds are northerly.

The headquarters of the Joint Fisheries Research Organization in Nyasaland will be transferred to Monkey Bay within a year and it will then be possible to undertake more detailed work on the hydrology of the southern portion of the Lake.

R_M VALUES IN THE GAS-LIQUID CHROMATOGRAPHY OF STEROIDS

By B. A. KNIGHTS and Dr. G. H. THOMAS

Department of Anatomy, University of Birmingham

CLAYTON[1] has shown that the retention time ($r_{(n+a+b+c+\cdots)}$) of a sterol methyl ether on gas-liquid chromatography may be expressed in the form:

$$r_{(n+a+b+c+\cdots)} = r_n \times k_a \times k_b \times k_c \times \cdots$$

where r_n is the retention time of the unsubstituted nucleus and $k_{a,b,c}$ . . . are group retention factors for a series of non-interacting substituents at positions *a,b,c*, etc. Quantitative investigations (to be published) have also been made by us, where we have considered the logarithm of the retention time of a steroid as being made up of the additive contributions of the individual substituents together with that of the nucleus to which they are attached.

We wish now to relate these observations to the theoretical studies which have formed the basis of similar quantitative work on the behaviour of compounds in paper chromatographic systems.

Bate-Smith and Westall[2] defined a function, R_M, for paper chromatography as:

$$R_M = \log\left(\frac{1}{R_F} - 1\right)$$

R_M is a function of the free energy of the compound, which in turn can be regarded as being made up of the sum of the free energies of the various groups of which the molecule is composed. It follows that R_M values for components of a molecule contribute additively to its chromatographic mobility.

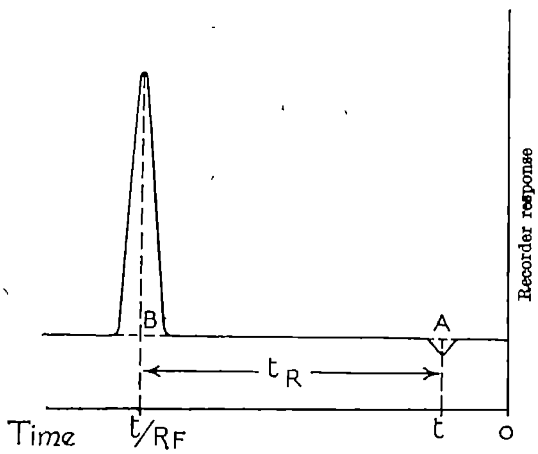

Fig. 1. Elution diagram. O, time of injection, *A*, air peak

The application of these concepts in the structural analysis of steroids has been reviewed by Bush[3].

The theory of gas-liquid chromatography differs from liquid-liquid chromatography only by virtue of the added complication arising from the compressibility of the mobile phase[4]. R_F has the same chromatographic meaning in both systems. In gas chromatography, the flow-rate of the mobile phase increases continuously as it advances down the column; since there is a corresponding increase in the rate of movement of the compound, the R_F remains constant[5]. In the chromatogram shown in Fig. 1 the time taken for the gas front to travel the length of the column is given by the time-interval (t) between the start of the chromatograph (O) and the appearance of the negative air peak (A). The retention time (t_R) of the substance is given by the interval AB and can be expressed as:

$$t_R = \frac{t}{R_F} - t = t\left(\frac{1}{R_F} - 1\right)$$

The relative retention time (r) using a standard x run under the same chromatographic conditions is:

$$r = \frac{\left(\frac{1}{R_F} - 1\right)}{\left(\frac{1}{R_{Fx}} - 1\right)}$$

Therefore:

$$\log r = R_M - R_{Mx}$$

It follows then, that the logarithm of the relative retention time of a substance is made up of the additive contributions of the individual groups (g) together with the log contribution for the relative retention time of the nucleus (N):

$$\log r = \Sigma \Delta R_{M_g} + \log^r N$$

The above relationship is implicit in our previous work. The group retention factor (k) described by Clayton can be related to R_{M_g} by the expression:

$$\log k = \Delta R_{M_g}$$

In order to conform to the existing nomenclature in paper chromatography we feel that there is some advantage in retaining the terms ΔR_{M_g} and ΔR_{M_r} to denote changes in log resulting from differences in structure of the type defined by Bush[3], that is, ΔR_{M_g} − $A\,\Delta \log r$ value due to the simple substitution of another group for a hydrogen atom; ΔR_{M_r} − $A\,\Delta\log r$ value due to a change in molecular structure other than the simple substitution of a hydrogen atom, for example, epimerization of a hydroxyl group, etc.

The work presented here was carried out with the object of testing with what degree of accuracy ΔR_{M_g} values for substituents could be determined by gas chromatography. We are indebted to Prof. W. Klyne for providing samples of mono-substituted steroids from the Medical Research Council Steroid Reference Collection. Compounds were chromatographed on 'Celite 545' (85–100 mesh) coated with 6 per cent '*QF*-1-0065' (a fluorinated alkyl silicone[6]). The running conditions were as follows: temperature, 250°; inlet pressure, 22 p.s.i.; flow-rate, 58–62 ml./min. The time of emergence was measured from the negative air peak and the relative retention times were calculated using cholestane as standard.

Table 1. RELATIVE RETENTION TIMES OF SOME STEROID HYDROCARBONS ON '*QF*-1-0065'

Steroid	r	$\log^r N$
5α-Androstane	0·18	− 0·75
5β-Androstane	0·17	− 0·78
5α-Pregnane	0·28	− 0·55
5β-Pregnane	0·25	− 0·61
5α-Cholestane	1·00	0·00
5β-Cholestane	0·90	− 0·05

The $\log^r N$ values of some androstanes, pregnanes and cholestanes are presented in Table 1. It can be seen that the order of elution is $C_{19} < C_{21} < C_{27}$, and that for pairs of hydrocarbons differing only in their configuration at C–5, the 5β-steroid is eluted ahead of its 5α-isomer. In Table 2 are given ΔR_{M_g} values for ketone and hydroxyl substituents at selected positions of the steroid molecule. These values were determined by subtracting, from the $\log^r$ of the compound listed in Table 2, the log r value of the appropriate steroid devoid of the functional group. The results serve to illustrate the degree of accuracy with which these values can be calculated and, further, to show that the contribution of a substituent depends not only on its chemical nature but also on its position in the molecule and its configuration. Such differences are of considerable importance in providing constitutional information about the structure of unidentified compounds.

A detailed analysis of ΔR_{M_g} values of functional groups in the steroid molecule is being undertaken and the results will be discussed fully elsewhere.

Table 2. ΔR_{M_g} CONTRIBUTIONS OF KETONE AND HYDROXYL GROUPS FOR COMPOUNDS CHROMATOGRAPHED ON '*QF*-1-0065'

Group	Steroid*	ΔR_{M_g}
3-Ketone	5α-Androstan-3-one (1·02)	0·76
	5β-Androstan-3-one (0·93)	0·75
	5α-Androstane-3,17-dione (4·72)	0·77
	5β-Androstane-3,17-dione (4·27)	0·77
	5α-Pregnan-3-one (1·60)	0·76
	5β-Pregnan-3-one (1·51)	0·79
	5α-Cholestan-3-one (5·46)	0·74
	5β-Cholestan-3-one (5·04)	0·75
3-OH (equatorial)	5α-Androstan-3β-ol (0·54)	0·48
	5β-Androstan-3α-ol (0·50)	0·48
	5β-Androstan-3α-ol-17-one (2·23)	0·49
	5α-Pregnan-3β-ol (0·83)	0·47
	5β-Pregnan-3α-ol (0·77)	0·50
	5α-Cholestan-3β-ol (3·03)	0·48
	5β-Cholestan-3α-ol (2·88)	0·50
17-Ketone	5α-Androstane-17-one (0·80)	0·65
	5β-Androstan-17-one (0·72)	0·64
	5α-Androstane-3,17-dione (4·72)	0·67
	5β-Androstane-3,17-dione (4·27)	0·66
	5α-Androstan-3α-ol-17-one (2·18)	0·66
	5α-Androstan-3α-ol-17-one acetate (3·29)	0·66
	5β-Androstan-3α-ol-17-one (2·23)	0·65
	5β-Androstan-3α-ol-17-one acetate (3·04)	0·65
20-Ketone	5β-Pregnan-3α-ol-20-one (2·76)	0·55
	5β-Pregnan-3α-ol-20-one acetate (3·84)	0·59
	5β-Pregnane-3,20-dione (5·37)	0·58
	5α-Pregnane-3,20-dione (5·90)	0·57

* The relative retention times (cholestane used as standard) of the compounds are given in brackets.

This investigation was supported, in part, by a grant made by the Ford Foundation to Sir Solly Zuckerman, to whom we are indebted.

We thank the Caroline Harrold Fund for a grant to cover the purchase of a Pye argon gas chromatograph and the London Rubber Co. for funds to support a university research fellowship for one of us (B.A.K.).

USE OF THE COMPLEXES OF THIOL CARBOXYLIC ACIDS WITH NICKEL IN CHEMICAL ANALYSIS

By V. M. BHUCHAR

National Physical Laboratory, New Delhi, 12

DETERMINATION of nickel in microquantities with dimethylglyoxime and its higher homologues is well known[1]. Besides these nitrogen and nitrogen co-ordinating ligands, other ligands have been suggested for its determinations. These are nitrogen and oxygen co-ordinating: 8-hydroxy quinoline[2], and nitrogen and sulphur co-ordinating: dithioxamide (rubeanic acid)[3a] and thioxine[3b]. Sulphur and oxygen co-ordinating ligand, for example, β-thiol propionic acid[4], has also been used recently for the determination of nickel; and in the following the results with similar ligands, namely, α-thiol acetic acid and *o*-thiol benzoic acid for determining nickel spectrophotometrically, are briefly reported. The use of the former in polarographic determination of nickel[5,6], and also in spot detection of chromium[7,8] in presence of titanium, has been described already by me.

Nickel (spec. pure), 0·2979 gm., was dissolved as perchlorate to make a 500-ml. solution. α-Thiol acetic acid (B.D.H.) and *o*-thiol benzoic acid (m.p. 162°–164°) were used.

Beckman's *p*H meter model *H*2 and Hilger Watts Uvispectrophotometer No. 700,308 were used. The two reactants were allowed to react together and the *p*H was set with ammonia or caustic soda solution as desired. The solution was then made up to volume.

The following observations were made:

(1) Nickel gives coloured complexes with thiol acetic acid. In aqueous centimolar solution of nickel the colour of the complex is yellowish-green in acidic solution showing pink at a *p*H of about 5 and is violet at *p*H 7 and above. The absorption curve of the coloured complex at a *p*H of 8·5 is shown in Fig. 1.

(2) Similar absorption curves are obtained whether one uses ammonia or caustic soda for setting the *p*H.

(3) There are two absorption maxima in the curve, one at 515 mμ (referred to later as position '*X*') and the other a broad, rather flat absorption band in the region 600–640 mμ (referred to later as position '*Y*').

(4) The plot of the absorbance at *X* with the change of *p*H is shown in Fig. 2 (curves *A* and *B*). The absorbance measured at *X* becomes essentially constant between *p*H 7–9. When ammonia is used for setting of *p*H, the absorbance falls off rapidly after *p*H 9 (curve *A*). But in case caustic soda is used for the same purpose, the absorbance increases after *p*H 9 and once again becomes constant between *p*H 11–12; at still higher *p*H's the absorbance increases again (curve *B*).

(5) At these regions, of *p*H 7–9 and of *p*H 11–12, the molar absorbancy indexes at *X* are 98 and 126, respectively, and Beer's Law has been found to obey for either of these regions of *p*H's for nickel concentrations varying between 2·5–50 μgm. nickel/ml. by using 40 mm. light path, or by using Ilford filter OG_1 with a Spekker absorptiometer. Therefore, either of these ranges of *p*H, that is, 7–9 and 11–12, may be usefully exploited for analytical purposes. The anions normally met with in chemical analysis, namely, sulphate, phosphate, pyrophosphate, tartrate, chloride, perchlorate, citrate and oxalate, do not essentially interfere in this determination.

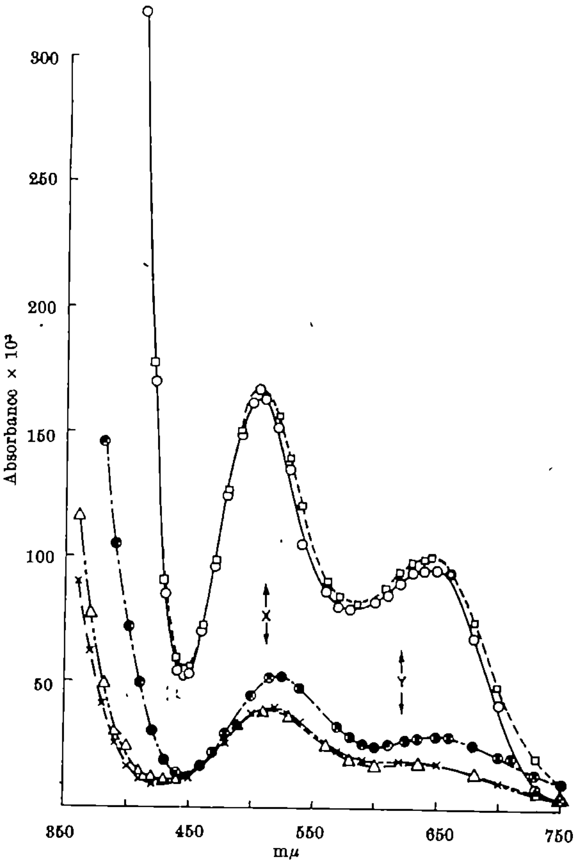

Fig. 1. Absorption curves of nickel solutions containing 23·95 μgm. nickel/ml. ($4{\cdot}08 \times 10^{-4}$ *M*) complexed with·
A (△), α-thiol acetic acid (excess), *p*H 8·5 set with ammonia;
B (×), α-thiol acetic acid (excess), *p*H 8·5 set with caustic soda;
C (○), α-thiol acetic acid (excess), *p*H 11·5 set with caustic soda;
D (○), *o*-thiol benzoic acid (excess), *p*H 8·5 set with ammonia;
E (□), *o*-thiol benzoic acid (excess), *p*H 8·5 set with caustic soda

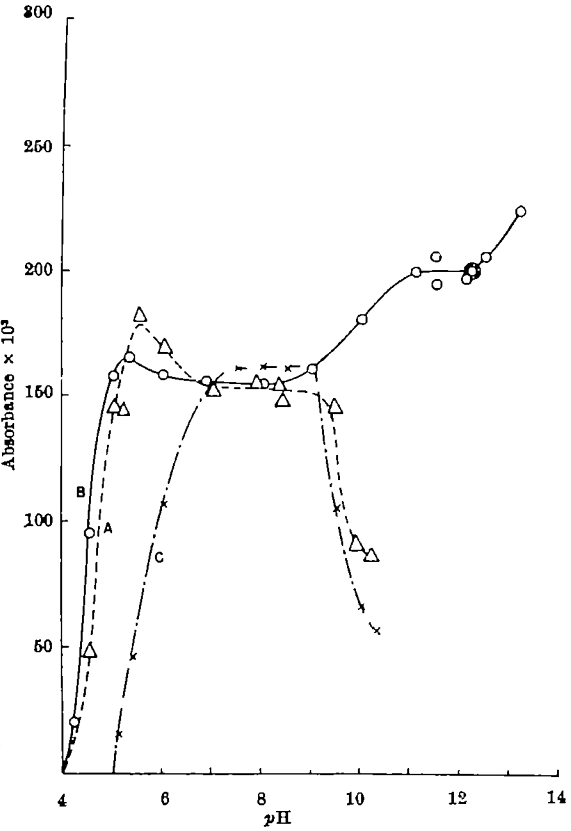

Fig. 2. Change of absorbance at 'absorption maximum' at *X* with varying *p*H of the solution containing 23·95 μgm. nickel/ml. (that is, 4·08 × 10^{-4} *M*) complexed with: *A* (Δ), a large excess of α-thiol acetic acid using ammonia for setting *p*H, *light path 40 mm.*; *B* (○), a large excess of α-thiol acetic acid using caustic soda for setting *p*H, *light path 40 mm.*; *C* (×) (7 molar) excess concentration of *o*-thiol benzoic acid using caustic soda for setting *p*H, *light path 10 mm.*

(6) This reagent can be used for determination of a few ions, namely, chromium, tungsten, uranium and nickel[8], molybdenum[9] and cobalt[10]; and is not specific to nickel. Manganese and indium do not interfere. The results of these determinations are being communicated elsewhere.

Observations regarding determination of nickel spectrophotometrically with *o*-thiol benzoic acid are also represented in Figs. 1 and 2. It may be noted that the *o*-thiol benzoic acid complex has molar absorbancy indexes 404 and 196, respectively, at 505 mμ and 635 mμ, and that analytically this complex is four times more sensitive than the α-thiol acetic acid complex.

No attempt is made here to offer any constitutional formula of the complex. The following observations in this respect, however, may be of interest.

The variation of the absorbance with the change of *p*H (Fig. 2) offers an interesting study. The coincidence of the inflexion of curve *B* at *p*H 5 and the rise of the curve *C* at the same *p*H is significant. The absorption curves at *p*H's greater than 5 have similarity of forms, especially for incidence of an absorption band at position *Y* for comparative points on curves *B* and *C*. The behaviour in case of thiol–acetic complex (curve *B*) may be explained by suggesting that more than one complex co-exist at *p*H's 5–9. Mention may be made here of the suggestion of Leussing *et al.*[11] regarding the co-existence of both monomeric and polynuclear species of complexes in solutions of nickel complexed with α-thiol acetic acid. The behaviour at higher *p*H's than 9 is again complicated. The comparative examination of these is already under study and will form the subject of another communication.

As stated earlier, in case of the thiol–acetic complex the molar absorbancy index between the region of *p*H 11–12 is about 30 per cent more than that in the region of *p*H 7–9. In this respect my observations are at variance with those of Christopher and Hamme[12] inasmuch as the latter have depicted that the absorbance between *p*H 7–12·25 remains constant. This is not borne out by Fig. 2 (curve *B*).

Attention may probably be directed to Fig. 1 in that in the case of thiol–acetic complex the position of absorption maximum at *X* between *p*H 11–12 shifts by 7 mμ bathochromically to 522 mμ, and also there is a change in the shape of the absorption spectrum at *Y* at *p*H's higher than 9.

NON-DISSOCIABILITY OF THE METAL COMPONENT OF D-α-HYDROXY ACID DEHYDROGENASE BY CHELATING AGENTS

By Dr. TERENZIO CREMONA* and Dr. THOMAS P. SINGER
Edsel B. Ford Institute for Medical Research, Henry Ford Hospital, Detroit

SINCE the simultaneous finding in two laboratories[1,2] that ethylenediamine tetraacetic acid (EDTA) and other chelating agents reversibly inhibit the D-α-hydroxy acid dehydrogenase of yeast (DHAD, 'anaerobic lactic dehydrogenase'), the mechanism of this effect has been the subject of considerable controversy. Reduced to its essentials, the question is whether chelating agents act by resolving this and related metal-flavoproteins to inactive flavoprotein, as asserted by Curdel *et al.*, or whether they act by forming an enzymatically inactive holoenzyme chelate, as suggested by Tubbs[5] and maintained by us[6–8]. As more fully discussed else-

* Fellow of the Comitato Nazionale Energia Nucleare.

where[3], a definitive answer to this question transcends in importance the particular observations involved, since a clear understanding of the action of chelating agents is essential for any interpretation based on their use as diagnostic agents in the field of metal flavoproteins. The purpose of this article is to present evidence incompatible with the assumption that the action of chelating agents on DHAD is the removal of its metal component.

We have previously reported that both DHAD and the closely related zinc-flavoprotein, D-lactic cytochrome reductase, which undergoes reversible inhibition by chelators in the same manner, may be extensively reactivated following inhibition by chelators without added metals[4]. This was accomplished by the removal of uncombined chelator on 'Sephadex', followed either by dialysis in the cold to dissociate protein-bound chelator or by incubation at 10°–45°. The latter technique, as applied to the reductase, resulted in the finding that both the rate and the extent of this 'spontaneous' reactivation depend on the temperature. These experiments were interpreted to show that the main reason for the inhibitory effect of chelating agents on these two enzymes is the formation of a chelated holoenzyme which is unable to bind substrate. Owing to the instability of the chelated enzyme full reactivation was not reached in these studies. Thus the possibility remained that a part of the inactivation was due to secondary, irreversible changes in the chelated protein or to removal of the metal or both.

Recently, conditions have been found to stabilize the chelated forms of both DHAD and the reductase[8]. By means of these full reactivation of the reductase was attained without the use of metals. Unambiguous proof that removal of the metal plays no part in the inhibition of the reductase was obtained following the isolation of the enzyme in homogeneous form and the analytical demonstration that it is a zinc-FAD enzyme[10]. It was found that the zinc content of the enzyme remained constant throughout the cycle of reversible inactivation but the inhibited form contained 2 moles chelator (o-phenanthroline) per gm. atom of zinc present[11].

Notwithstanding these facts, in a recent article dealing with the effect of acid ammonium sulphate on DHAD, Iwatsubo and Curdel[12] maintain that their original hypothesis of the mode of action of chelators is correct, although the data presented do not concern the action of chelators. In the hope of settling this question, we wish to present some data which clearly show that under the conditions used by these workers chelators do not dissociate the metal component of DHAD.

Following treatment with EDTA, the pH stability curve of the inactive DHAD is sharper and different from that of the untreated enzyme. The pH of maximum stability is 6·8. Dialysis at this pH results in full reactivation of the EDTA-inhibited enzyme (Fig. 1). Since no added metals are used in this experiment, reconstitution of the holoenzyme is precluded as a mechanism of the reactivation, and, hence, inactivation occurs solely because of chelation, not because of removal of the metal.

Although the lability of DHAD has prevented its isolation in sufficiently pure form to provide additional evidence from analytical demonstration that the inactive enzyme contains stoichiometric amounts of metal, zinc analyses are meaningful in showing that the reactivation by dialysis is not due to spurious contamination of the dialysing fluid with zinc. It was found that the zinc content of the preparation is the same before (4·8 mμmoles/mgm. protein) as after reactivation (4·7 mμmoles/mgm.).

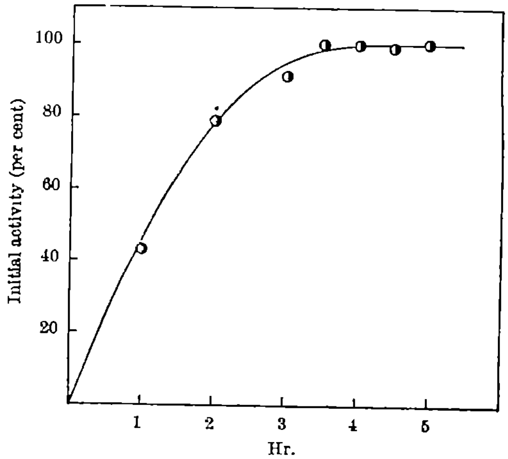

Fig. 1. Reactivation of DHAD by dialysis without added metals. Conditions: inactivation with 0·8 m*M* EDTA, *p*H 6·8, for 15 min. at 30°, reactivation, following passage through a column of 'Sephadex *G*-25' (equilibrated with 50 m*M* phosphate, *p*H 6·8) at 0°, by dialysis at 0°, under nitrogen, against 50 m*M* phosphate – 1 m*M* D-lactate, *p*H 6·8

Further evidence in support of the conclusion that EDTA inhibits DHAD by chelation is shown in Fig. 2. As demonstrated earlier for the reductase[6], both the rate and the extent of the 'spontaneous' reactivation depend on the temperature of incubation, and the fraction of enzyme in the active form may be readily varied by the mere readjustment of the temperature. Analytical studies in the case of the reductase have shown that the reversible equilibria are[11]:

$$\text{En}-\text{Zn} + \text{chelator} \rightleftarrows \underset{\textit{inactive}}{\text{En–Zn–chelate}} \rightleftarrows \underset{\textit{active}}{\text{En–Zn–chelate}} \rightleftarrows \text{En–Zn} + \text{chelator}$$

Thus a temperature-dependent intramolecular shift of the chelator occurs from catalytically inactive to active form. In the case of DHAD the same intramolecular shift of the chelator is indicated by the fast inactivation elicited by cooling a reactivated

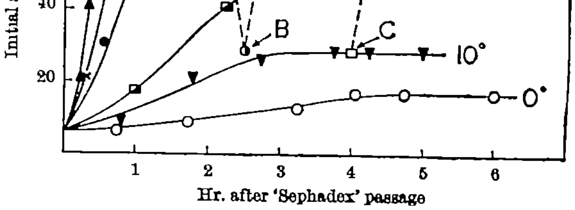

Fig. 2. Reactivation of DHAD at various temperatures. Samples of the inactivated, 'Sephadex'-passed enzyme (Fig. 1) were incubated in 50 m*M* phosphate – 1 m*M* D-lactate, *p*H 6·8, under nitrogen, at a concentration of 32 mgm. protein/ml. at the temperatures indicated. Aliquots were removed for assay as shown. At time *A* an aliquot was cooled from 38° to 10°; at point *B* it was reheated to 38°. At *C* an aliquot was heated from 10° to 38°

sample (point *A*, Fig. 2). A corresponding rate of inactivation at 10° would occur only at very high concentrations of *free* EDTA, whereas the actual concentration of EDTA in this experiment was very low, since only protein-bound EDTA was present.

The two reasons which led Curdel and Labeyrie[3] to postulate and maintain that the inhibition of DHAD by EDTA proceeds by removal of the metal were as follows. (1) These authors, when testing reactivation without prior removal of unreacted chelator, found that only Zn^{++} and, to a small extent, Co^{++} reactivated the enzyme. This apparent specificity was interpreted to show that (*a*) zinc is the prosthetic group, and (*b*) EDTA acts by dissociating zinc from the enzyme. They further observed that the Zn^{++}-reactivated enzyme has the same kinetic constants (K_M and $V_{max.}$) for D-lactate as the untreated one, while the constants of the Co^{++}-reactivated enzyme are different[3]. This was interpreted as confirming both of the conclusions mentioned. As to the first observation, Boeri *et al.*[2] reported two years ago that a series of divalent metals reactivate the EDTA-inhibited enzyme, provided that uncombined chelator is removed before adding the metal. The following results show that Zn^{++} is only slightly more effective than other divalent cations and that, therefore, the presumed specificity does not exist.

Samples of the EDTA-treated enzyme used in the experiment of Fig. 1, following 'Sephadex' passage, were incubated for 5 min. at 30° as follows: 1·89 mgm. protein in 0·1 *M* phosphate, *p*H 6·8, 0·15 ml. total volume, containing added metal at concentrations varied from 1×10^{-4} *M* to $8{\cdot}3 \times 10^{-4}$ *M*. Aliquots were assayed by the ferricyanide method[2]. Activity was calculated at infinite metal concentration from double reciprocal curves. The reactivation reached with different metals, expressed as percentage of the activity of the untreated enzyme, with *apparent* K_M for the metal in parentheses, were: Zn^{++}, full reactivation ($1{\cdot}25 \times 10^{-6}$ *M*); Co^{++}, 88 per cent ($1{\cdot}3 \times 10^{-6}$ *M*); Mn^{++}, 84 per cent ($1{\cdot}75 \times 10^{-6}$ *M*); Fe^{++}, 74 per cent ($1{\cdot}66 \times 10^{-6}$ *M*). The apparent K_M values show that the results cannot be interpreted as being due to traces of Zn^{++} in the other salts used.

As to the second reason, the apparent dependence of the constants of the reactivated enzyme on the metal used has also been observed by the authors and presented a paradox until recently. It has now been established, however, that if precautions are taken to stabilize the enzyme, the same K_M values are obtained in untreated, 'spontaneously' reactivated, and metal-reactivated samples, regardless of the metal used. When differences occur, they are the consequence of secondary changes in the protein and are as evident with Zn^{++} as with any other metal used for reactivation, provided that substrates other than lactate are tested. With lactate only minor differences are observed[7].

SEROLOGICAL HETEROGENEITY OF NORMAL HUMAN HÆMOGLOBIN

By Dr. G. R. E. NAYLOR and Mrs. M. E. ADAIR

Department of Pathology and Physiological Laboratory, Cambridge

In work reported previously[1] the reactions of anti-adult-hæmoglobin sera with hæmoglobin prepared from adult blood and from umbilical cord blood were studied by Oakley and Fulthorpe's gel-diffusion method[2]. In this method antiserum is allowed to diffuse from one side and antigen preparation from the other into a central column of gel. A band (really a disk) or bands of precipitate form in this layer; the number of bands of precipitate is an indication of the least number of antigen–antibody systems concerned in the reaction. The gel used was 1 per cent agar and the antisera showed one band of red precipitate with normal adult hæmoglobin and two bands of red precipitate with cord-blood hæmoglobin. This result was given by a considerable number of the anti-adult-hæmoglobin sera, but among those examined later three behaved differently: one showed two bands of red precipitate with adult hæmoglobin and three red bands with cord-blood hæmoglobin; one showed one red band with adult and three with cord-blood hæmoglobin; the third showed only one red band both with adult and with cord-blood hæmoglobin.

At the suggestion of Dr. C. G. Pope, gelatine was substituted for agar in diffusion experiments and was found to increase the resolution of bands of precipitate: for example, with cord-blood hæmoglobin, the antiserum which had shown one red band in agar showed four red bands in gelatine.

Glass tubes of 20-cm. length and 3-mm. calibre were bent into the form of the letter J; the narrow calibre allowed the economical use of antisera and the shape enabled the central column of plain gelatine to be introduced without contamination by the reactants. 0·16 per cent hæmoglobin was mixed with an equal volume of 6 per cent gelatine at 37° C.; 0·6 ml. of the mixture was introduced into the short limb of a tube and left for 2 hr. in a refrigerator to solidify.

Three per cent gelatine at 37° C. was added to the long limb of the tube to give a column of 20 mm. and, after this had solidified, 0·2 ml. undiluted antiserum was added to the long limb of the tube above the plain gelatine. The tubes were stoppered and stored at 1° C. Gelatine and hæmoglobin preparations were dissolved in a solution which contained 0·71 per cent sodium chloride and 0·2 per cent sodium bicarbonate; 1 in 10,000 merthiolate was present in each reagent.

All antisera described in this and the previous article[1] had been obtained from rabbits after injection of samples of the same preparation of hæmoglobin from a single bleeding of one adult (C. W.). Five preparations of hæmoglobin were examined in gelatine diffusion experiments: that used for the injection of rabbits, two obtained from the blood of adults, J. P. and R. N., and two from the umbilical cord-blood of babies E. A. and V. C. Antisera and antigens were stored at − 20° C.

With good precipitating antisera, which contained about 5 mgm. antibody per ml., bands of precipitate appeared in gelatine diffusion experiments in 7–17 days; the bands were not coloured when they first formed, but as they increased in intensity the red colour became obvious. Changes in appearance continued for more than 2 months.

In agar diffusion experiments[1], antiserum 23*D* had shown one band of red precipitate with adult hæmoglobin and two with each of four preparations of cord-blood hæmoglobin. In gelatine diffusion experiments, this antiserum showed two red bands with adult hæmoglobin and more than two with cord-blood hæmoglobin (Fig. 1: Nos. 1, 2 and 3). Antiserum 52*E*, which had shown one red band in agar both with adult (C. W.) and with cord-blood hæmoglobin (E. A.), showed in gelatine diffusion experiments two or more red bands with hæmoglobin (C. W.) and four red bands with hæmoglobin (E. A.) (Fig. 1: Nos. 5 and 7).

In comparisons between the reactions in gelatine of antisera from different rabbits with the same preparation of hæmoglobin, differences were observed in the number of red bands, their distance apart, their width and the position of the most intense band relative to the others (Fig. 1: Nos. 6 and 8; Nos. 2 and 7). This diversity was also observed when using antisera obtained from the same rabbit after different numbers of courses of injections (Fig. 1: Nos. 1 and 4: antisera 23*D* and 23*F* were obtained from rabbit 23 after 4 and after 6 courses of injections respectively).

In comparisons between the reactions of the three preparations (J. P., C. W., R. N.) of adult hæmoglobin with the same antiserum, differences in the number of red bands, their distance apart and their width were observed with some antisera (Fig. 1: Nos. 5 and 6); this diversity may suggest differences in the relative proportions of antigenically distinct hæmoglobins in the blood of different adults. In similar comparisons between the reactions of two preparations of cord-blood hæmoglobin with the same antiserum, differences were also observed with some antisera (Fig. 1 : Nos. 2 and 3); the two preparations of cord-blood hæmoglobin E. A. and V. C. contained respectively 87 and 83 per cent of fœtal (alkali-resistant) hæmoglobin estimated by the method of Jonxis[3].

With a given antiserum, a greater number of red bands was generally observed with preparations of cord-blood hæmoglobin than with preparations of adult hæmoglobin; with cord-blood hæmoglobin the distance between the upper and lower limits of precipitation in the plain gelatine layer was always greater than with adult hæmoglobin (Fig. 1: Nos. 1, 2 and 3; Nos. 5, 6 and 7).

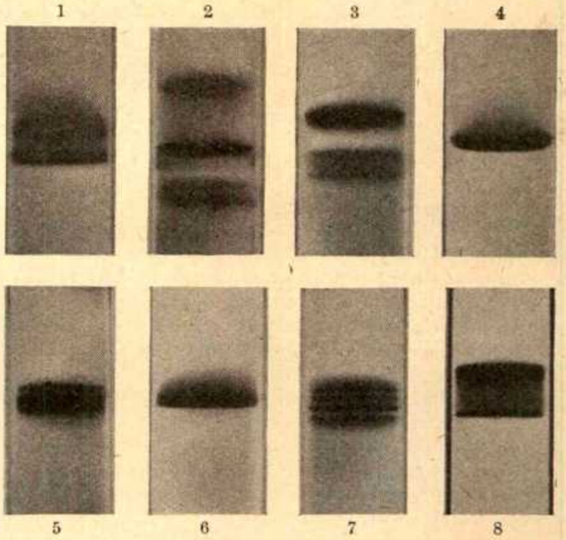

Fig. 1. Precipitates formed in gelatine when four anti-adult-hæmoglobin sera (23*D*, 23*F*, 52*E*, 35*F*) react with preparations of hæmoglobin from three individual adults (J. P., C. W., R. N.) and from two individual babies (E. A., V. C.). (1) 23*D* with J. P.; (2) 23*D* with E. A.; (3) 23*D* with V. C.; (4) 23*F* with J. P.; (5) 52*E* with C. W.; (6) 52*E* with R. N.; (7) 52*E* with E. A.; (8) 35*F* with R. N.

In experiments with seven antisera, the number of red bands observed with the three preparations of adult hæmoglobin ranged from 1 to 4 and with the two preparations of cord-blood hæmoglobin from 2 to 5. In some reactions the maximum number of bands was not easy to determine because one or more bands had diffuse margins and were incompletely resolved. To reduce the risk of artefacts which may be caused by temperature changes, the tubes were observed infrequently and more bands might have been visible at some stage. Wilson[4] has emphasized that the number of bands may diminish during the course of a diffusion experiment: bands may not be stationary and, if moving at different rates, can become superposed; increase in width can cause bands which have been distinct to overlap.

After the experimental tubes had been stored at 1° C. for 11 months, most of the bands of precipitate were still bright red. In a few experiments with adult hæmoglobin as the antigen, one of two red bands had become brown; this may indicate differing degrees of stability[5] in antigenically distinct hæmoglobins.

In a few experiments, a band which was not detectably coloured was seen in addition to red bands. Bands in which colour was not visible during several months of observation were narrow and faint; they may have been due to a reaction involving an antigen from the red cell other than hæmoglobin or to a reaction between a hæmoglobin and its antibody in which the reactants were present in low concentration.

Fractions of adult hæmoglobin (J. P.) of low and high R_F value were obtained from an 'Amberlite *IRC* 50' column after a single elution at 1° C. with a buffer of *p*H 5·84 which contained 0·07 *M* sodium chloride, 0·09 *M* trisodium citrate and 0·01 *M* citric acid. The fractions were compared using nine antisera. With seven antisera, both fractions showed two or more bands of red precipitate and with five antisera the number of bands shown by the two fractions differed. After 11 months, bands formed in experiments with the fraction of high R_F were still bright red, but those shown by the fraction of low R_F had become brown[6].

Analyses of precipitates formed by mixing undiluted antiserum with hæmoglobin solutions have shown that the anti-adult-hæmoglobin sera were capable of completely precipitating adult hæmoglobin and a cord-blood hæmoglobin which contained as much as 87 per cent of fœtal hæmoglobin[7]. Two possible explanations are suggested for the complete precipitation of cord-blood hæmoglobin: antibodies to adult hæmoglobin cross-reacted with fœtal hæmoglobin; or, the adult hæmoglobin preparation (C. W.) used for injection of rabbits contained traces of fœtal hæmoglobin[8,9] which had stimulated antibody production. These two explanations are not mutually exclusive.

Recent physico-chemical investigations have indicated that normal human hæmoglobin is to be regarded as a group of related substances rather than a single substance. By column chromatography, six hæmoglobins have been demonstrated in blood from one normal adult and seven in one cord-blood[9,10].

The results obtained in gelatine diffusion experiments with adult and with cord-blood hæmoglobin as antigen could be provisionally explained by the presence of antigenically distinct hæmoglobins in a single sample of blood from one individual, the relative proportions differing from person to person. The diversity of results obtained with different antisera (Fig. 1: Nos. 1 and 4; Nos. 2 and 7; Nos. 6 and 8) might be partly due to differences in the concentration of antibodies to these different hæmoglobins in antisera obtained from individual rabbits, or from the same rabbit after different numbers of courses of injections. In an antiserum prepared against a mixture of antigenically distinct hæmoglobins, some or all of the antibodies to one hæmoglobin may cross-react with one or more other hæmoglobins and the proportion of antibodies which cross-react may differ in different antisera. Such differences of proportion may contribute to the diversity of the results obtained with different antisera.

In the reactions of some antisera with adult hæmoglobin two, narrow, red bands of great and similar intensity and colour developed close together. Such reactions are not easily explained by the presence of one major (79–83 per cent[11]) and several minor hæmoglobin components in adult blood demonstrated by physico-chemical methods. The antisera were not reacting solely with minor components because they were able to precipitate adult hæmoglobin completely.

We thank Dr. C. V. B. Walker for gifts of adult blood, and Mr. D. P. Gatherum and Mr. S. W. Patman for the photographs. We are grateful for the use of a room maintained at 1° C. in the Low Temperature Station, Cambridge.

ISOMERIC FORMS OF HÆMOGLOBIN H

By PROF. REINHOLD BENESCH* and DR. RUTH E. BENESCH
Department of Biochemistry, College of Physicians and Surgeons, Columbia University
AND
PROF. HELEN M. RANNEY and ALAN S. JACOBS
Department of Medicine and Heredity Unit, Albert Einstein College of Medicine, New York

IN the course of an investigation of the functional properties of hæmoglobin H[1], it was observed that starch granule electrophoresis of the hæmolysate from patients with hæmoglobin H disease occasionally showed two fast components instead of one. It is the purpose of this article to report that hæmoglobin H will migrate electrophoretically either as one or as two components, depending solely on the ionic strength and the *p*H of the medium.

Blood was obtained from the two patients previously studied[1] and the methods used were those described earlier[1]. The hæmoglobin was applied to the starch blocks either as oxy- or as carbon monoxy-hæmoglobin without any influence on the results.

The electrophoretic behaviour of hæmoglobin H is illustrated in Fig. 1 and Table 1. A single fast component is observed on starch granules, on starch gel or on paper at an ionic strength of 0·1 at *p*H 7·5. When the ionic strength was decreased, separation into two components occurred in such a way that the amount of the slower component increased at the expense of the faster with decreasing ionic strength (cf. Table 1). When the two components which appear at an ionic strength of 0·033 were eluted and re-subjected to electrophoresis at an ionic strength of 0·1, only a single component with the original mobility was obtained (Fig. 2).

Table 1. INFLUENCE OF IONIC STRENGTH AND *p*H ON STARCH BLOCK ELECTROPHORESIS OF HÆMOGLOBIN H

(*A*) *p*H = 7·5

Ionic strength	Per cent of total hæmoglobin 'slow' H	 'fast' H
0·033	20·0	12·5
0·066	5·5	30·0
0·100	none	33·4

(*B*) Ionic strength = 0·033

*p*H	Per cent of total hæmoglobin 'slow' H	 'fast' H
7·5	20·0	12·5
7·0	7·0	28·5
6·5	none	38·7

The relative amounts of 'slow' and 'fast' H vary somewhat with different lots of starch.

---

* Established investigator of the American Heart Association.

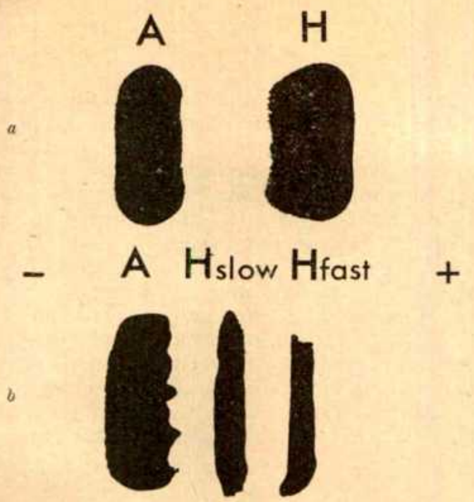

Fig. 1. Starch-block electrophoresis of whole hæmolysate. *a*, Phosphate buffer pH 7·5, $\mu=0{\cdot}10$, 16 hr.; *b*, phosphate buffer pH 7·5, $\mu=0{\cdot}033$, 16 hr.

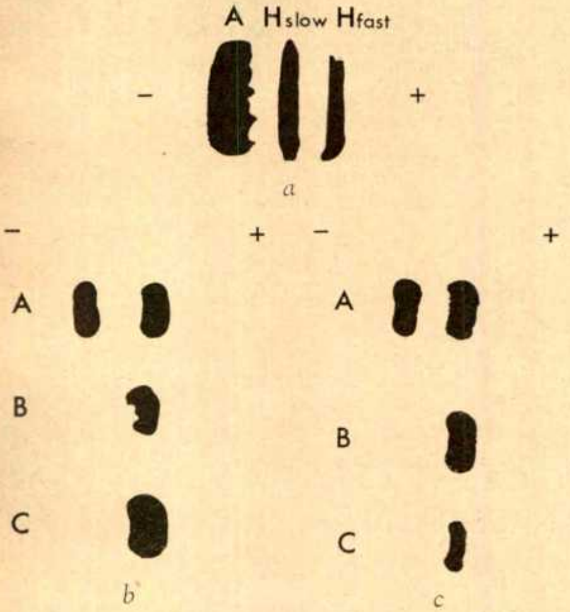

Fig. 2. Reversal of transformation. *a*, Starch-block electrophoresis of whole hæmolysate, phosphate buffer $\mu=0{\cdot}03$, pH 7·5, 16 hr.; *b*, single starch block, phosphate buffer $\mu=0{\cdot}03$, pH 6·5, 16 hr. *A*, Whole hæmolysate; *B*, fraction 'H slow' eluted from block of Fig. 2*a*; *C*, fraction 'H fast' eluted from block of Fig. 2*a*; *c*, single starch block, phosphate buffer $\mu=0{\cdot}10$, pH 7·5, 16 hr. *A*, Whole hæmolysate; *B*, fraction 'H slow' eluted from block of Fig. 2*a*; *C*, fraction 'H fast' eluted from block of Fig. 2*a*

A similar relationship was observed with respect to changes in pH. Thus, only a single component was present at pH values less than 7 even at an ionic strength as low as 0·03. Above pH 7 the slower component appears and its relative amount increases with increasing pH at constant ionic strength (Table 1). As in the case of the ionic strength-dependent transformation, the process was found to be reversible, since the two components obtained at pH 7·5 travelled with the same mobility when they were re-subjected to electrophoresis at pH 6·5 (Fig. 2).

In summary, therefore, it appears that hæmoglobin H can exist in two forms. That which is stable at high ionic strength has the greater mobility towards the anode and therefore a larger negative charge. Under the influence of low ionic strength and increasing pH, a progressive transformation to a slower and therefore less negatively charged species takes place. The rate of transformation is evidently slow enough to permit the separation of the two species during electrophoresis.

The nature of the two components was further investigated by total amino-acid analysis and molecular weight determinations. Complete amino-acid analyses on the Spinco amino-acid analyser model 120 revealed no significant differences in the composition of the two components or between them and the single component of hæmoglobin H which results from electrophoresis in high ionic strength. The analysis of the latter material was reported previously[1].

As can be seen from Table 2, neither the molecular weight nor the sedimentation constant showed any significant difference at low and high ionic strength.

Table 2

	Ionic strength = 0·033	Ionic strength = 0·10
Mol. wt.	71,000 ± 5,000	68,000 ± 4,000
$S_{20,w}$	4·55	4·55

The hæmoglobin H was eluted from the starch with phosphate buffer pH 7·5 of the indicated ionic strength and concentrated by ultrafiltration as described previously (ref. 1). The data were obtained on a Spinco model *E* analytical ultracentrifuge, using a Wratten filter No. 29 and Kodak 1 *N* spectroscopic plates. Molecular weights were determined by the Archibald method (ref. 16). The sedimentation velocity of the hæmoglobin at the two ionic strengths was determined simultaneously in a double cell rotor using a 1° positive wedge. In this way a difference of 0·1 sedimentation unit could have been detected.

The two electrophoretically distinguishable components must therefore be regarded as identical in primary structure and molecular weight.

The occurrence of two fast components in hæmoglobin H disease has been encountered in a number of laboratories[2-4]. Silvestroni *et al.*, for example, described five such cases. The only difference found between the faster component (H_1) and the slower component (H_2) was a "fetal type of U.V. spectrum" in the latter. Their claim that hæmoglobin H_2 is Bart's hæmoglobin and therefore consists of γ-chains[5], whereas hæmoglobin H_1 consists of β-chains is unacceptable in the absence of amino-acid analyses, especially since neither fraction was alkali-resistant. Bart's hæmoglobin would be particularly easy to detect by isoleucine analysis alone, since 4γ-chains contain 16 isoleucine residues[6], in contrast to α- and β-chains, which do not contain this amino-acid. (No significant amounts of isoleucine were found in any of our fractions and neither component was significantly alkali-resistant.) It is therefore possible that Silvestroni *et al.* were dealing with the same type of isomerization as described here. In general, it would seem advisable in all such cases to investigate the effect of ionic strength and pH and to exercise caution in using mobility as an absolute criterion for the identification of hæmoglobins.

Transformations of the kind described here are not without precedent in protein chemistry. Perhaps the most thoroughly investigated example is the case of serum albumin. This protein has been shown to undergo a reversible transformation in the pH-range of 3·5–4·5 to a form with a greater electrophoretic mobility towards the cathode[7,8]. Within this range two components are observed, the proportion of the faster increasing with decreasing pH. The transformation of the slow isomer (*N*) to the fast one (*F*) was found to involve the binding of three additional protons. It is noteworthy that a species with a mobility slower than *N* was observed on the alkaline side of the isoelectric point, that is, between *p*H 10 and 11 (ref. 9). Related phenomena were also encountered with ovalbumin and γ-globulin by Phelps and Cann[10], although here the interpretation is complicated by buffer ion effects.

Wishnia *et al.*[11] observed a *p*H-dependent transition between two species of conalbumin near *p*H 4, which is reversible and which they were able to correlate with proton binding by the rapid flow titration technique[12].

A sharp discontinuity in the mobility versus *p*H curve of tobacco mosaic virus protein takes place between *p*H 5 and 7 (ref. 13). In contrast to the other examples, profound changes in molecular weight, which occur in the same *p*H range, have to be taken into account in this case.

The interpretation of our observations on hæmoglobin H is analogous to those given in the investigations of these proteins. Hæmoglobin H, which is a tetramer of 4 β^A-chains, is known to be far less stable than hæmoglobin A, the tetramer of 2 α^A- and 2 β^A-chains[14]. (The stability of hæmoglobin H also seems to vary from patient to patient. Thus, the hæmoglobin H from patient N. H. was considerably more stable than that from L. G. Nevertheless, the hæmoglobin H from both sources showed the isomerization.) It is therefore not surprising that it can exist in more than one isomeric form. More specifically, the transformation of the fast to the slow component can be pictured as follows.

At a *p*H sufficiently above the isoelectric point to allow the accumulation of enough negative surface charges, a decrease in ionic strength results in repulsion between these charges and therefore in some unfolding. Some previously inaccessible basic sites thus become available for proton binding which leads to a decrease in the net negative charge on the protein and therefore a slower mobility towards the anode. This change can be reversed either by an increase in ionic strength, that is, decreasing the forces between the existing charges on the surface of the molecule, or by actually reducing the number of such charges, that is, a lowering of the *p*H towards the isoelectric point.

The presence of inaccessible proton binding sites in hæmoglobin is a well-established fact, discovered by Steinhardt and Zaiser with the rapid flow titration technique[15]. The lesser intrinsic stability of hæmoglobin H apparently permits the liberation of such groups in the neutral *p*H range, in contrast to hæmoglobin A, where they become available only in acid solution.

ELECTROPHORETIC AND IMMUNOLOGICAL STUDIES ON STRUCTURAL SUB-UNITS OF HUMAN CERULOPLASM

By Dr. M. D. POULIK
American National Red Cross, Washington, D.C.

SINCE the isolation of the copper-binding protein ceruloplasmin by Holmberg and Laurell[1] in 1948, chemical investigations of this protein have been limited. Curzon has envisaged a structure in which each copper atom provides a strong link between side-chains of four parallel peptide chains which are further stablized by disulphide bridges and hydrogen bonds[2]. Scheinberg, Aisen and Morell suggested that 16 free carboxyl groups, probably in aspartyl or glutamyl residues, are the sites of the copper binding[3]. The presence of three *N*-terminal amino-acids[4] would indicate at least the same number of polypeptide chains present.

Methods for the electrophoretic separation of structural sub-units of proteins have been developed and applied successfully to the study of haptoglobin[5], α-2 macroglobulin[6] and human γ-globulins[7]. The methods applied in this work on human ceruloplasmin were essentially the same as those described in ref. 6. Ceruloplasmin was obtained from two large-scale preparations and was estimated to be 94–96 per cent pure by Grabar's immunoelectrophoresis, starch-gel electrophoresis according to Smithies and two-dimensional zone electrophoresis[8]. Both samples contained a small amount of another copper protein of lower mobility in the starch-gel[9]. When dissolved in 6 or 8 molar urea in alkaline buffers the ceruloplasmins lost their blue colour and on electrophoresis in starch-gel (prepared in 8 molar urea and formate buffer) several protein zones were obtained.

The pattern for ceruloplasmin treated with urea alone suggests that at least one fast-migrating sub-unit and three slower ones can be dissociated as shown in Fig. 1*A*. It must be emphasized that the multiple slow-migrating zones may represent aggregation and isomerization and not necessarily separate sub-units[10]. On reduction and alkylation, by a method previously described[6], the number of slower

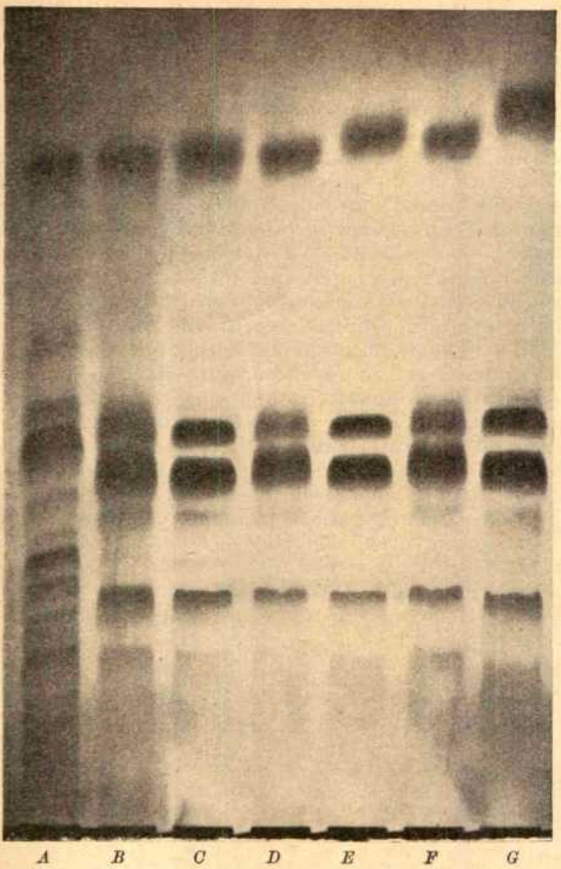

Fig. 1. Effect of reduction and alkylation on urea starch-gel electrophoretic pattern of ceruloplasmin. Ceruloplasmin treated with 8 *M* urea (*A*); ceruloplasmin reduced with varying concentrations (0·01 *M*, 0·1 *M* and 0·2 *M*) of mercaptoethanol in 8 *M* urea (*B*, *D*, *F*). Ceruloplasmin reduced with the above concentration of mercaptoethanol and then alkylated with 0·05 *M*, 0·25 *M* and 0·5 *M* iodoacetamide (*C*, *E*, *G*)

migrating zones was considerably reduced, and a simpler pattern emerged as shown in Fig. 1*B–G*. Performing the electrophoresis in urea starch-gels containing 0·02 *M* mercaptoethanol yielded identical patterns. Essentially similar patterns were obtained with four different batches of ceruloplasmin. However, when heterogeneous (possibly polymerized) ceruloplasmin[8] showing several bands by staining for oxidase activity and protein was used for similar experiments a more complicated pattern resulted. The simple pattern observed (Fig. 1*G*) would be consistent with the existence of several non-identical sub-units. Treatment of ceruloplasmin with mercaptoethanol alone (0·01–1·0 *M*) does not effect the electrophoretic and oxidase patterns in starch-gel (prepared in absence of urea). The amount of copper, determined after treatment with urea and subsequent dialysis, does not seem to be appreciably decreased. The same holds true for reduced and alkylated ceruloplasmin.

Further evidence of the dissociation of the ceruloplasmin molecule into several sub-units was obtained by ultracentrifugation in the presence of urea and by immunological methods. The apparent *S* rates of ceruloplasmin which had previously been reduced and alkylated in the presence of urea, and of ceruloplasmin treated with urea alone were found to be lower than that of untreated ceruloplasmin.

Moreover, material treated with urea (with or without reduction and alkylation) remained soluble after removal of the urea by dialysis. This behaviour may be contrasted with that of normal and abnormal γ-globulins which, after reduction and alkylation in the presence of urea, become insoluble on dialysis. When the material which had been treated with urea and afterwards dialysed was analysed by the Ouchterlony method, using highly specific rabbit anticeruloplasmin sera (the generous gift of Dr. J. Thorbecke-Hochwald, New York University) the presence of at least two immunologically active components could be detected as shown in Fig. 2. Since spurring occurs one may speculate that at least three antigenic determinants are present on the native molecule; however, additional lines of precipitation were observed, too faint to be reproduced. The results obtained were substantiated by immunoelectrophoresis in agar-gel. Identical results were obtained also with the reduced and alkylated materials. Furthermore, the immunological results were unaffected if both the Ouchterlony analysis and the immunoelectrophoresis were conducted on undialysed materials. A full report of these investigations will be given elsewhere. The immunological results described so far are suggestive of the existence on the protein molecule of several antigenic determinants which may be exposed by suitable treatment. Thus, enzymatic degradation of γ-globulin or albumin will expose new determinants[11–13]. A chemical method of degradation was used by Pope and Stevens[14] to uncover new antigenic groups of toxin of *Corynebacterium diphtheriae* and the results reported here suggest that chemical methods can, indeed, be used for such a purpose.

Electrophoretic results obtained by treatment with urea alone indicated that partial dissociation of the native ceruloplasmin occurred and that some of the

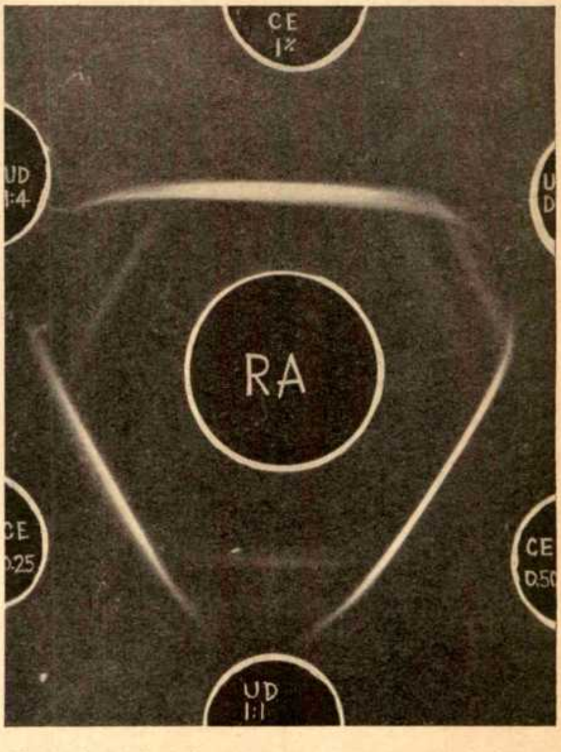

Fig. 2. Ouchterlony plate showing precipitin lines obtained with native and treated ceruloplasmin. *CE*, native ceruloplasmin (1, 0·5, 0·25 per cent); *UD*, ceruloplasmin treated with 8 *M* urea which was afterwards dialysed against normal saline (0·95 per cent) for 24 hr. at 4° C. and suitably diluted; *RA*, specific anticeruloplasmin rabbit serum

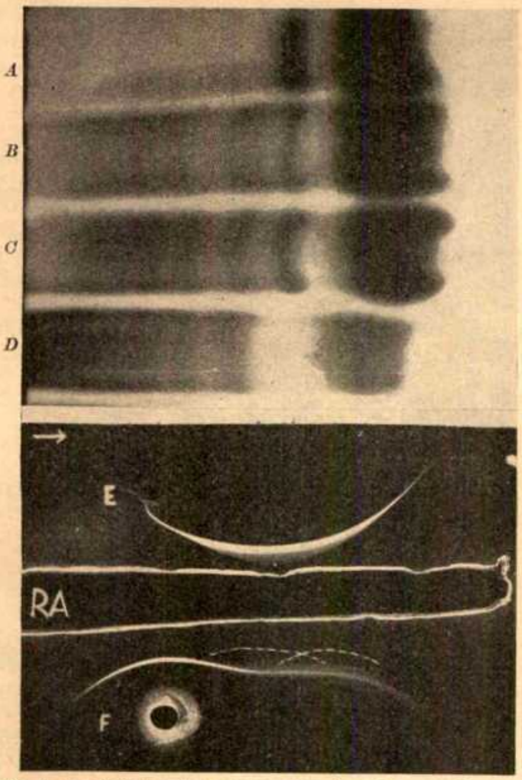

Fig. 3. Vertical starch-gel electrophoresis and agar-gel immunoelectrophoresis of ceruloplasmin treated with acetate, acetate-ascorbic acid and acetate–EDTA

Starch-gel patterns of ceruloplasmin: *A*, dialysed against saline; *B*, dialysed against 0·1 *M* acetate buffer (*p*H, 4·0); *C*, dialysed against 0·1 *M* acetate buffer in the presence of ascorbic acid (5 mgm./ml. of buffer); *D*, dialysed against 0·1 *M* acetate buffer in the presence of 0·1 *M* EDTA. Agar-gel immunoelectrophoresis patterns of ceruloplasmin: *E*, dialysed against saline; *F*, dialysed against 0·1 *M* acetate buffer in the presence of 0·1 *M* EDTA; *RA*, a specific rabbit anticeruloplasmin serum

sub-units are probably held together by weak forces. When the native ceruloplasmin was dialysed against 0·1 *M* acetate buffer (*p*H 4·0) or against either ascorbic acid or ethylenediamine tetraacetic acid (EDTA) in presence of the acetate buffer, profound changes of the electrophoretic patterns were noted. Thus, filter paper electrophoresis and agar-gel electrophoresis have shown two components instead of the usual one. Vertical starch-gel electrophoresis uncovered several new slower-migrating protein zones in addition to the two usually present as shown in Fig. 3. Using two-dimensional zone electrophoresis, the new slower-migrating zones were identified with the faster filter paper electrophoresis component. These results also show that ceruloplasmin can be rendered heterogeneous by such methods of treatment[9]. Furthermore, several new antigenic components were demonstrated by agar-gel immunoelectrophoresis, especially in the material treated with acetate–EDTA (Fig. 3*F*).

These preliminary results suggest that native ceruloplasmin can be dissociated into several non-identical structural sub-units. Investigations of the active side of the oxidase activity and the mode of copper binding should be facilitated once these sub-units are isolated. It is possible that genetic and pathological variants of this protein may be found at the level of its structural sub-units.

I am indebted to Dr. Oliver Smithies and Dr. G. A. Jamieson for their help in the preparation of this manuscript.

LOCAL MEMBRANE CURRENT IN THE OUTER SEGMENTS OF SQUID PHOTORECEPTORS

By W. A. HAGINS, H. V. ZONANA and R. G. ADAMS

National Institute of Arthritis and Metabolic Diseases, National Institutes of Health, Bethesda, Maryland; Naval Medical Research Institute, Bethesda, Maryland; and Johns Hopkins Medical School, Baltimore, Maryland

WHEN a quantum of light is absorbed by any of the millions of rhodopsin molecules in a dark-adapted human retinal rod there is a high probability that the cell will become excited[1]. Other photoreceptors may be equally sensitive to single photons[2]. The mechanism linking each of such a large number of photopigment molecules to the sensory output of one cell is not yet known; but two physical processes have been suggested as playing a part in conveying information about absorbed photons from the light-absorbing organelles of photoreceptors to the distal neurones of the visual system. The first is diffusion of light-created electrons and holes through the ordered structures in which photopigments are usually concentrated. It has been shown that such migration in the form of excitons (coupled electron-hole pairs) is improbable[3]; but photoconductivity may exist in rods under some conditions[4] and might contribute to the spread of excitation within outer segments (or to the flow of current through them). Its importance in living cells is still to be shown. A second suggestion is that light might release locally a chemical transmitter substance which diffuses to the dendrites of nearby neurones[5]. But the slow speed of molecular diffusion limits its range to a few microns during the short latency of vision, while the distal neurons of the visual system are often separated from the sites of light absorption by the much greater lengths of the receptor cells. Therefore, some additional mechanism seems required to account for signal transmission in long photoreceptors. A likely possibility is displacement of the cell membrane potential by light-induced flow of local membrane current, for such local currents are believed to produce the graded receptor potentials often seen in other kinds of sensory cells[6] and, in one case, to account for spread of excitation from sites where stimuli act to regions of the receptors where nerve impulses are generated or transmitter substances are released[7]. There is, in fact, evidence that some photoreceptor cells do depolarize when illuminated, although the source of the depolarizing current was not located[8].

This article reports some experiments which suggest that such locally originating receptor currents are capable of transmitting signals along both cell bodies and outer segments of squid photoreceptors.

The squid retina, like that of the octopus, is a packed array of long cells of which the photopigment-bearing processes (here called 'outer segments' by analogy with vertebrate rods and cones) are covered with piles of microvilli[9]. The outer segments are attached to nucleated cell bodies which lie just outside a dense layer of black pigment. From the cell bodies axones are given off which pass through a plexus and enter the optic lobe situated behind the eye[10]. Apart from the photoreceptors, only a few very small glial and pigment-bearing cells are present.

When live retinæ were isolated from dark-adapted animals (*Loligo pealii*) and sliced into strips about 100μ thick by cuts parallel with the long axes of the receptors, the strips survived and gave good electroretinograms for several hours in cold moist air (5°–10° C.) on the stage of an inverted microscope. In order to avoid light adaptation of the slices, all manipulations and observations were made in infrared radiation of wave-lengths 0·9–1·0μ rendered visible with the aid of photoelectric image converters. Micropipettes were inserted into the slices and zones in the layer of outer segments were stimulated with movable spots of red light 30–40μ in diameter. The positions of receptors, stimulus, and electrodes were recorded continuously with a motion picture camera photographing the screen of an image converter attached to the microscope. One frame from a record is shown in Fig. 1. The slice lies with the long axes of the receptors in the plane of the page. The tip of pipette *A* lies at the inner limiting membrane *L* while that of *B* has been thrust into the retina so that its tip (arrow) is surrounded by the proximal parts of the same group of outer segments which end at *A*. The cell bodies and axons lie below the pigmented layer *P*. The stimulus *S* enters the slice perpendicularly to the plane of the page, passing through parts of the outer segments of about 200 receptor cells.

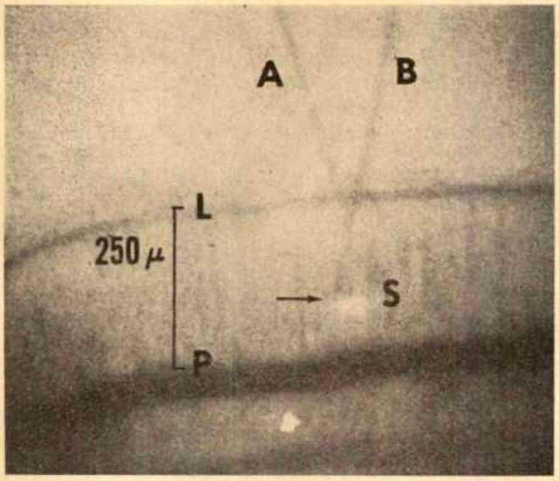

Fig. 1. Slice of living squid retina photographed with light of wave-lengths 900–1,000 mμ. Electrode *A* at inner limiting membrane *L*. Tip of electrode *B* at arrow in layer of outer segments just above pigmented zone *P*. Stimulus spot *S* consisted of wave-lengths 630–650 mμ

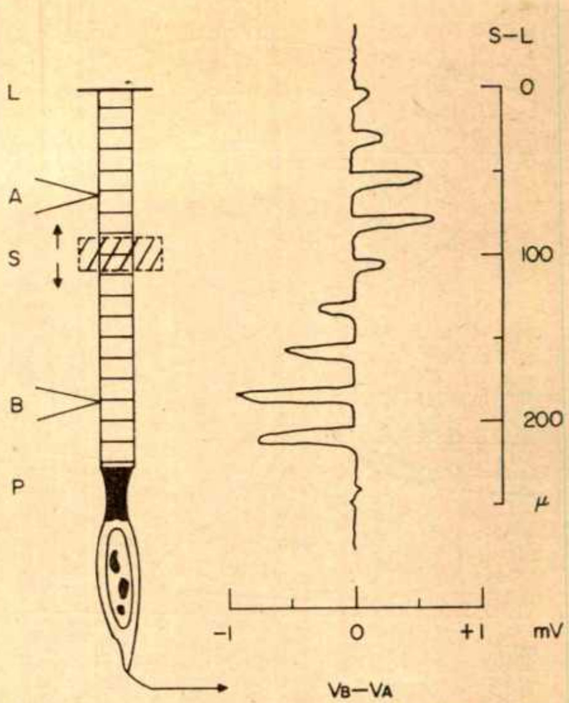

Fig. 2. Extracellularly recorded potentials in a retinal slice with stimuli at various depths in the layer of outer segments. Ordinate, distance of stimulus *S* from internal limiting membrane *L*. Abscissa, potential difference between electro tips. Stimulus intensity equivalent to 3×10^{11} photons cm.$^{-2}$sec.$^{-1}$ at 500 mμ. See legends of Figs. 1 and 3 for explanation of symbols

When two pipettes filled with sea-water and with tips 1–5μ in diameter were placed as shown in Fig. 1, no resting potential difference was recorded between them. This was not surprising, since the receptor outer segments are not more than 4–8μ in cross-section and the electrodes would be expected to create new extracellular spaces or enlarge existing ones by destroying some photoreceptors during penetration of the slice. However, when an intermittent light stimulus was moved along a line connecting the two tips, small graded slow potentials were seen which resembled the externally recorded electroretinogram[11]. The sign and amplitude of the potentials depended on the position of the spot, the tip nearest the light going negative to the one more distant (Fig. 2). An intermediate position was always found where the stimulus produced no potential difference. At this point the stimulus caused both electrodes to go equally negative relative to a distant indifferent electrode.

Detailed two-dimensional plots of the potential field in a locally illuminated slice showed a minimum confined to the illuminated region and a maximum spread out over the cell bodies the outer segments of which were in the path of the stimulus. Fig. 3 shows this for a stimulus placed near the tips of the outer segments. When the stimulus was moved deeper, the minimum remained centred on it, but the maximum did not shift in position. The topography of the field

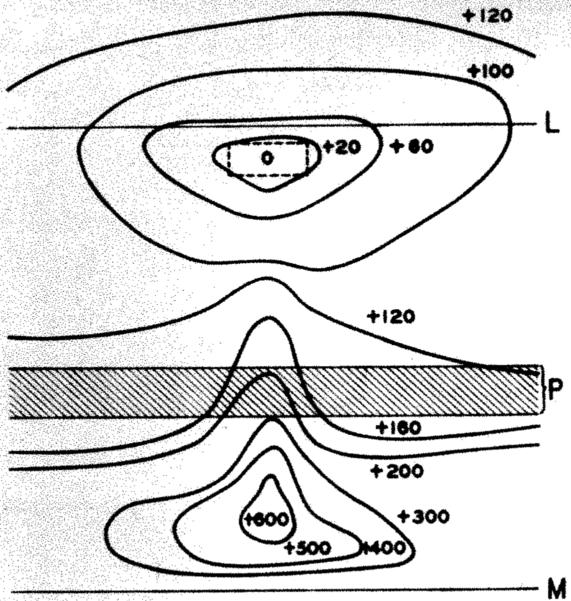

Fig. 3. Isopotential contours in a retinal slice illuminated near the tips of the outer segments. Internal limiting membrane at *L*, stimulus indicated approximately by dashed square. Cell bodies of receptors lie between pigment layer *P* and glial membrane *M*. Contours indicated in microvolts relative to potential at centre of stimulus. Plot was made by inserting a microelectrode into the slice in the direction from *L* to *M* and recording responses relative to an electrode at *L* as the stimulus was swept along a line parallel to *L*. Stimulus intensity equivalent to 6 × 10^{10} photons cm.$^{-2}$ sec.$^{-1}$ at 500 mμ

was independent of stimulus intensity below 10^{11} photons cm.$^{-2}$ sec.$^{-1}$ (500μ equivalent) because the amplitudes of the responses, like those of the electroretinogram[11b], were directly proportional to light intensity in this range. However, the region of negativity around the light became relatively larger when stimuli more intense than 10^{13} photons cm.$^{-2}$ sec.$^{-1}$ (500 mμ equivalent) were applied. This effect was believed due to saturation of the current-producing mechanism of the directly illuminated outer segments combined with excitation of surrounding cells by stray light scattered from the primary beam.

The fields observed were those to be expected if positive membrane current arose in the cell bodies of the illuminated group of receptors, flowed through the intercellular spaces and entered the outer segments where photons were actually being absorbed. Such a current should change the membrane potentials of the cells which produce it. Attempts were therefore made to record these changes directly with intracellular electrodes.

If a pipette with tip diameter less than 0·2μ and filled with potassium chloride solution (resistance 50–100 megohms in 3 *M* potassium chloride) was substituted for electrode *B* of Fig. 1 and carefully tapped into a slice, many regions were encountered in all retinal layers which had negative resting potentials of 10–50 mV. When an electrode was in such a region, illumination of the outer segments in line with its tip produced graded potentials of the usual form but much larger than those recorded with large pipettes filled with sea-water and always positive in sign. In bright light, the responses nearly abolished the resting potential but did not reverse it. Within 2 min. after penetration, the resting potential and light response usually disappeared, declining together until only a small but typical extracellular response from surrounding cells remained. Since the electrode resistance never increased more than 5 megohms when it was inserted into a region giving large responses, it is likely that the tip was in a photoreceptor, because their interiors formed the largest and most numerous spaces present. On this assumption, the space constants of the outer segments were estimated by measuring the amplitudes of the large responses elicited by stimuli at varying distances along the cells from the electrode tip. Values of 400–600μ were usually obtained. No intracellularly recorded action potentials were seen, perhaps because the photoreceptor axons were too severely depolarized by the injury associated with dissection and penetration; but it seems clear that light does produce local currents which markedly depolarize both cell bodies and outer segments and would be capable of initiating or modifying trains of spikes at the origins of the receptor axons.

The preceding results suggest that the action of light is to produce some local electrical change which allows current to flow into the outer segments within a few microns of the point where the photons are absorbed, but they say little else about what the change might be. However, some further information was obtained by light-adapting zones in the outer segments. When the tips of the outer segments the responses of which are shown in Fig. 2 were exposed to a flash containing 7·4 × 10^{14} photons cm.$^{-2}$ of wavelength 550 ± 10 mμ, the responses of the tips to subsequent test flashes were initially reduced more than tenfold, recovering their original responsiveness gradually over a period of 15 min. The unilluminated deeper parts of the same outer segments were not detectably affected by the adapting light. Adaptation of deeper zones produced corresponding effects. Intracellular recordings from the adapted cells showed no prolonged changes in their resting potentials, so that it is unlikely that their internal ionic composition was much affected by the light. Moreover, the adapting exposures were not great enough to activate more than 5 per cent of the rhodopsin in the illuminated zones, since the extinction coefficient of the squid photopigment is less than 20,000 cm.^{2} m.mol.$^{-1}$ at 550 mμ (ref. 12). This result is reminiscent of the drastic reduction in responsiveness of vertebrate retinæ by adapting exposures whose photochemical effects are minor[13].

Two alternative explanations can be offered for the ability of light to adapt zones in outer segments without depolarizing the receptors or destroying their photopigment. First, adaptation might alter the intercellular concentration of some ion which carries current into the receptors. The intercellular spaces seem very small in electron micrographs[9d] and their ionic composition could be greatly affected by a flow of charge that would leave the cytoplasm of the receptors almost unchanged. The 15-min. period required for an adapted zone to recover its sensitivity would then be due to diffusion of ions into the illuminated zones from neighbouring intercellular spaces. However, the diffusion of most small ions in water seems to be nearly two orders of magnitude too fast for this, and it would be necessary to suppose that diffusion is greatly retarded in the spaces between the outer segments. Local adaptation can also be explained in a second more abstract way. If the photopigment molecules were organized into functional units in which single absorbed photons inactivated at least 20 chromophores for a time, the observed adaptation would result. Further work will be necessary to assess the value of these suggestions; but it is clear, nevertheless, that the flow of the receptor current depends to a remarkable degree on highly localized changes induced by light in the outer segments of the receptors. The roles of electron-hole migration and diffusion of transmitter substances thus seem restricted to signal transmission through distances of only a few microns from the sites of light absorption, if indeed they play any part at all in visual excitation in the squid retina.

A detailed account of these experiments and of the electrochemical basis of the receptor current of the squid retina will be published separately. We thank the staff of the Marine Biological Laboratory, Woods Hole, Massachusetts, for their help during this work, and Mr. M. W. Klein of the Engineering Research Development Laboratories, U.S. Army Corps of Engineers, Fort Belvoir, Virginia, for the loan of infrared optical equipment. The opinions expressed herein are ours and are not to be construed as representing those of the U.S. Navy or the naval service in general.

EXCYSTATION OF *EIMERIA ARLOINGI* (MAROTEL, 1905): STIMULI FROM THE HOST SHEEP

By A. R. B. JACKSON

Department of Veterinary Pathology and Bacteriology, University of Sydney

ALTHOUGH excystation of various species of *Eimeria* has been investigated for many years, no completely satisfactory explanation of the mechanism has been advanced. In some avian species free sporozoites may be obtained by first mechanically rupturing the oocyst wall to release the sporocysts and then treating these with a trypsin solution (*E. tenella*[1]) or a trypsin-bile solution (*E. acervulina*[2]). Such treatments fail to produce free sporozoites of *E. bovis*[3] or of the species infecting sheep.

Initially in this work numerous attempts were made to produce *in vitro* excystation using mechanical means and also various enzymatic preparations, both natural and synthetic, in different combinations and *p*H-levels. In no instance did excystation occur.

As a possible explanation of these negative results, it was thought that at least two separate stimuli might be required, these occurring in sequence in the rumen or abomasum, and the small intestine. With this in mind sporulated oocysts were treated successively in fluid collected from the rumen, abomasum and small intestine. This produced a low percentage of excystation. Further work showed that a high percentage of excystation could be obtained by first introducing oocysts into the rumen enclosed in a 'Cellophane' sac via a fistula (following Sommerville's technique[4]), then incubating them in a solution containing trypsin and sheep bile. It was not shown that a stimulus from the abomasum was required.

These two stimuli, the first provided by the rumen and the second by the trypsin-bile solution, were then further examined.

Stimulus from the Rumen

Attempts to provide this stimulus *in vitro* by using ruminal fluid gave variable and generally unsatisfactory results unless incubated under an atmosphere of carbon dioxide. This suggested a close similarity to the stimulus for larval exsheathment described by Rogers and Sommerville[5] and Rogers[6]. After application of this ruminal stimulus the only visible change that could be seen in the oocysts was a lifting or splitting of the cap over the micropyle. That a further change had occurred was demonstrated by their ability to excyst if afterwards incubated in a trypsin-bile solution. Other evidence of change include: the collapse of the oocyst contents when placed in a hypertonic solution, for example, of sodium chloride, normally used for floating oocysts; the staining of the inner wall (but not the sporocysts) a characteristic purple with methylene blue; the destruction of the oocyst and contents when placed in a solution of sodium hypochlorite. It is postulated that the stimulus activates an enzyme system within the oocyst which chemically alters both the inner wall of the oocyst and a supposed outer coat of the sporocyst.

The nature of this ruminal stimulus was investigated *in vitro* using methods similar to those described by Rogers[6]. The results in Table 1 show some of the features of the stimulus. All preparations were incubated at 39° C.

These results clearly indicate that carbon dioxide is the essential part of the stimulus. The addition of bicarbonate does not enhance its action, but anaerobic and reduced conditions do.

It was observed that when isotonic buffer solutions were used, subsequent attempts to excyst the oocysts resulted in the liberation of the sporozoites from the sporocysts, but although actively motile they were unable to escape from the oocyst. With dilute buffers the sporozoites were capable of leaving the oocyst through the micropyle. Sodium bicarbonate solution of 0·1 *M* and above acted similarly to isotonic solutions. Solutions more dilute than this resulted

Table 1. INDICATING THE ABILITY OF SOME GAS MIXTURES UNDER DIFFERING BUFFERED AND REDUCED CONDITIONS TO PROVIDE THE RUMINAL STIMULUS

Buffer	Gas phase	pH	Reducing agent	Oocysts activated per cent
Bicarbonate	Air	8·3	–	0
Phosphate	N_2	6·8	–	0
Bicarbonate	N_2	8·3	+	0
,,	N_2	8·3	–	0
,,	15 per cent CO_2: air	6·8	–	16
Phosphate	15 per cent CO_2: N_2	6·8	–	49
Bicarbonate	,,	6·8	–	47
,,	,,	6·8	+	64

in free sporozoites, the effect being augmented with increasing dilution. Complete excystation of those oocysts incubated in isotonic buffers could be obtained if they were washed in water prior to incubation in the bile-trypsin solution. The significance of these observations is discussed below.

Oocysts used in the following experiments were allowed to sporulate in distilled water. Oocysts which sporulated in a potassium dichromate solution produced somewhat different results as will be described here. Unsporulated or incompletely sporulated oocysts do not react to the ruminal stimulus.

(1) *Effect of carbon dioxide.* Fig. 1 indicates the increasing activity of the stimulus with increasing concentration of carbon dioxide in the gas phase. The type of buffer does not appear to alter the result significantly; anaerobic and reduced conditions do. Results for carbon dioxide and oxygen mixtures were essentially similar to those given for carbon dioxide and air. Although this action was first investigated as a stimulus from the rumen, it is possible that conditions in the small intestine may also be adequate to initiate the stimulus. Very high concentrations of carbon dioxide were not inhibitory.

(2) *Effect of temperature.* The control that temperature has on the stimulus is shown in Fig. 2. No activity occurred at 30° C. With temperatures above 46° C. the stimulus was effective, but viable sporozoites were not obtained.

(3) *Effect of reducing agents.* The addition of a reducing agent to the buffer solution generally increased the effectiveness of the stimulus as shown in Fig. 1. Three chemically unrelated agents—sodium dithionite, cysteine and ascorbic acid—were used. All were effective.

(4) *Effect of sodium chloride.* The addition of sodium chloride in increasing amounts from 0·01 to 0·2 *M* to the buffer solution did not significantly affect the carbon dioxide stimulus.

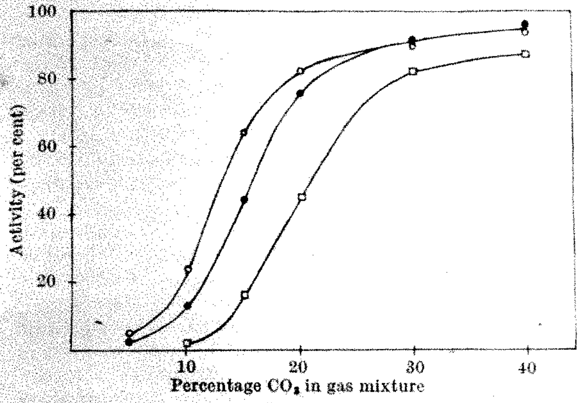

Fig. 1. Effect of increasing concentrations of carbon dioxide under aerobic, anaerobic and reduced conditions on the proportion of oocysts activated by the stimulus. Experiments were in sodium bicarbonate buffer at pH 6·8. Cysteine–hydrochloride 0·02 *M* was used as the reducing agent. Incubation at 39° C. for 8 hr. The measure of 'activity' was determined by the ability of oocysts to excyst when incubated in a trypsin-bile solution. □, CO_2 : air ; ●, CO_2 : N_2 ; ○, CO_2 : N_2 + cysteine

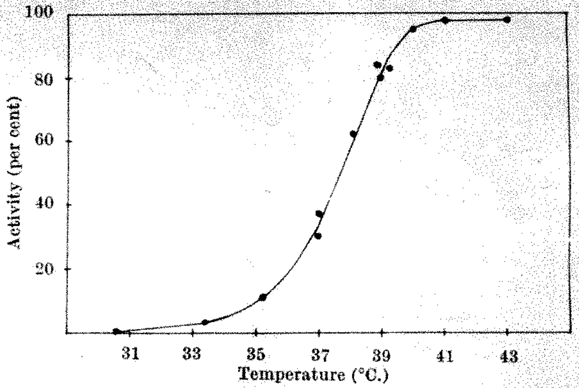

Fig. 2. Effect of temperature on the proportion of oocysts activated by the stimulus. Experiments were in sodium bicarbonate buffer at pH 6·8 with 20 per cent CO_2 : N_2 mixture incubated at 39° C. for 12 hr. The measure of 'activity' was determined by the ability of oocysts to excyst when incubated in a trypsin-bile solution

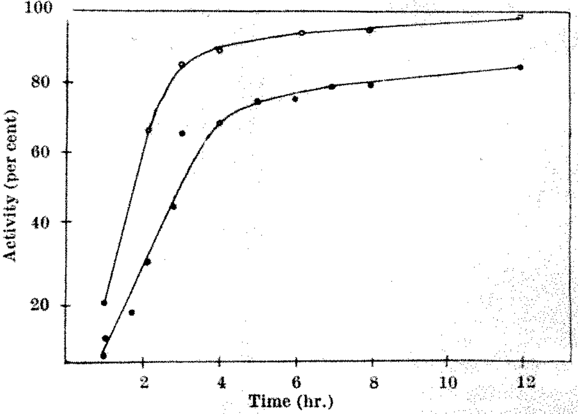

Fig. 3. Effect of time on the proportion of oocysts activated by the stimulus. Experiments were with CO_2 : N_2 gas mixtures and sodium bicarbonate buffer to give pH 6·8. Incubation at 39° C. The measure of 'activity' was determined by the ability of oocysts to excyst when incubated in a trypsin-bile solution. ○, 40 per cent CO_2 ; ●, 20 per cent CO_2

(5) *Time required for the stimulus to act.* Fig. 3 shows the effect of time on the proportion of oocysts activated by the stimulus. Most were affected after 6 hr., but with continued incubation the proportion was slowly increased.

(6) *Effect of potassium dichromate.* Oocysts which sporulate in potassium dichromate and are then subjected in turn to the ruminal stimulus and to incubation in a trypsin-bile solution show a lower excystation-rate than oocysts sporulated in distilled water. It is noteworthy that although a lower percentage excyst, and also a lower percentage show the characteristic purple staining with methylene blue, the destructive action of sodium hypochlorite affects a similar proportion of oocysts which have sporulated in potassium dichromate to those which have sporulated in distilled water. This would suggest that potassium dichromate does not affect the oocyst's ability to be influenced by the ruminal stimulus, but does reduce its permeability to the enzyme solution providing the second stimulus, possibly by an effect on the cap or micropyle.

Stimulus from the Small Intestine

The essential components of this second stimulus are trypsin and bile. In the foregoing experiments an excysting fluid of 0·25 per cent trypsin 1 : 250 and 10 per cent sheep bile in a phosphate–buffered balanced salt solution at *p*H 7·4 was used. Oocysts previously subjected to the ruminal stimulus will begin to excyst when incubated in this medium. The sporozoites become motile within the sporocysts, and, with the disappearance of the Stieda body, escape fairly rapidly into the cavity of the oocysts. They then proceed to move actively round the oocysts, their anterior end frequently making contact with the micropyle. In oocysts treated in water or buffers of low molar strength, the sporozoites push their way through the micropyle and escape. Following incubation the first free sporozoites are found after about 0·5 hr., the process continuing for some hours.

Both trypsin and bile must be present for the second stimulus to be effective. The stimulus was effective if the oocysts were added to a bile solution first, then, following washing, to a trypsin solution. It was not effective, however, if this procedure was reversed.

Trypsin may be replaced by papain. Sodium taurocholate (British Drug Houses) and 'Tween 80' had an action similar to bile. To ensure viability of the sporozoites the osmotic pressure and *p*H of the excysting fluid must be kept within physiological limits.

It is considered that the *in vitro* stimuli described here are essentially those which *in vitro* result in excystation. It is most probable that the initial stimulus in which carbon dioxide is the essential factor is effected within the rumen because relatively high levels of carbon dioxide are required. This is comparable with the stimulus for exsheathment of *Haemonchus contortus* larvæ[6]. Bile and trypsin, which constitute the second stimulus, would normally be encountered by oocysts in the small intestine. *In vitro* treatment with buffers of low osmotic pressure or washing in water is essential if escape of sporozoites from the oocysts is to be effected. Such treatment presumably causes the rupture of the thin membranous inner wall underlying the micropyle following its chemical alteration by the ruminal stimulus. Additional enzymes such as pepsin, pancreatin and lipase were not effective in replacing this step. It is considered that *in vivo* this may be accomplished by the physical conditions encountered by the oocysts within the gastro-intestinal tract, such as changes in hydrostatic pressure. It was noticed that oocysts within a 'Cellophane' sac in the rumen would start to break up after some hours. Hammond[3] reported the same observation on oocysts in 'Cellophane' sacs in the large intestine of the calf.

A limited number of non-quantitative observations were made on other species of *Eimeria* infecting sheep including *E. parva*, *E. intricata*, *E. faurei* and *E. nina kohl yakimovae*. It is probable that the sequence of excystation is essentially the same in all these species.

Limited observations on *E. tenella* from the fowl and *E. stiedae* from the rabbit suggest that the process of excystation in these species may be similar to those infecting the sheep. It would be interesting to compare quantitatively the stimuli required by species infecting different animal species.

I thank Prof. H. R. Carne and Mr. Sommerville for advice; and Prof. W. P. Rogers for helpful discussion.

ÆTIOLOGY OF 'WET-BELLY' IN RANCH-BRED MINK

By DR. C. K. GUNN

Superintendent, Experimental Fur Ranch, Summerside, P.E.I., Canada

THE external symptom of 'wet-belly disease' in mink is denoted by an area of wet, matted fur, surrounding the opening of the prepuce in male mink. This may vary in extent from 1 in. in diameter to an area extending over the whole abdominal surface. This is caused by a dribbling of the urine into the fur (Fig. 1). Because of the anatomical differences in the sexes, wet-belly is not common in female mink.

'Wet-belly disease' has become of considerable economic importance because of its increased incidence and the marked devaluation it causes in mink pelts. The latter results from the unprime, pigmented state of the leather (Fig. 2) underlying the matted, and frequently stained, fur in the affected area of skin over the abdomen.

This 'disease' has been attributed to a number of causes, including acidosis[1], nutritional anæmia[1], urinary calculi[2], and biotin deficiency[3]. Wet-belly was not correlated to ration composition[4], but to feeding of whole fresh-water fish[5], or feeding rations high in fat content[6,7], and to stress caused by handling[8]. Methods as being effective in preventing the condition include feeding choline[6,7] and feeding cooked potatoes[9].

Ranchers also noted that when high proportions of chicken waste, fish and tripe were used to replace horse meat in mink rations, 'wet-belly disease' became a major problem, with the number of defective pelts reaching 20–30 per cent of the kit male crop.

In 1960, experimental work was initiated at the Experimental Fur Ranch, Summerside, Prince Edward Island, Canada, on this condition. It was readily produced in 40–70 per cent of kit male mink by feeding rations containing high proportions of raw chicken waste, whole fish and beef tripe from August to December. (The ingredients of the rations were (per cent): chicken waste, 28·75; fish (small flounders and tom cods), 28·75; tripe, 5; horse meat, 15; cereal, 7·5; liver, 10; brewers' yeast, 0·5; milk powder, 0·5; canned tomatoes, 3·75; cod liver oil, 0·25.) The occurrence of the 'disease' coincided with the furring season and the onset of cold weather in the month of November. The incidence of the disease among 144 female mink receiving the wet-belly-inducing rations was less than 1 per cent.

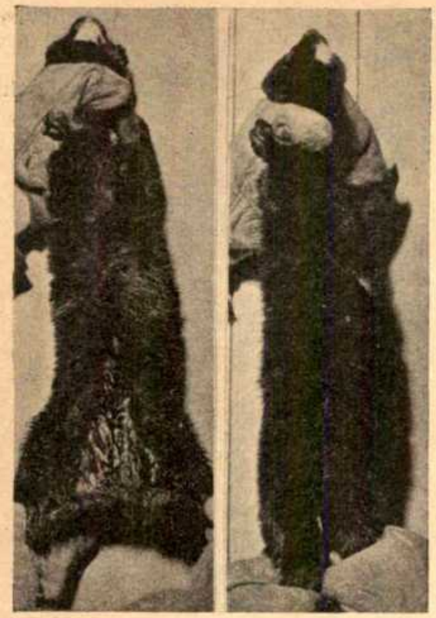

Fig. 1. Left, wet-belly disease; right, normal

The average body-weights of 33 male mink with 'wet-belly disease' and 39 normal mink on the same rations were not significantly different in the early stages of the disease on November 21 (1·58 and 1·61 kgm., respectively).

In two other experiments, using similar rations, the addition of 10 per cent fat (lard) caused no significant increase in the incidence of wet-belly among 144 male kit mink (1960 and 1961 seasons). The incidence was 27 cases of 'wet-belly' on the fat-supplemented rations and 31 cases on the rations without added fat.

Attempts to prevent 'wet-belly' among the above-mentioned mink, by the addition of a supplement containing buffering minerals, vitamins (including choline), lipotrophic factors, coenzymes and an anti-oxidant (supplement: dicalcium phosphate, sodium and potassium bicarbonate, magnesium sulphate, fumarate, aspartic acid, asparagine, cysteine, adenylic-5-acid, calcium pantothenate, choline, betaine, inositol, cyanocobalamin, bonemeal, milk powder, bran and wheat germ) were not effective. Attempts to cure the condition after its onset by the use of an antibiotic (chloromycetin), a sulphonamide (sulpha methoxypyridazine) and a chemical genito-urinary antiseptic (furadantin) gave inconclusive results with 82 cases of 'wet-belly disease'. It was noted in this investigation that the 'disease' had a high spontaneous resolution factor, and that frequent recoveries and relapses occurred among the male mink maintained on the 'wet-belly'-inducing ration throughout the winter and spring seasons.

The pathological findings were chiefly confined to an inflammation of the glans penis, terminal urethra and prepuce or sheath of the affected animals. In conjunction with these findings, it was also observed that unsheathing of the inflamed penis through the inflamed and constricted opening of the prepuce was painful. This is thought to cause the mink to allow the urine to dribble from the prepuce cavity through its opening on to the belly fur, giving rise to the external manifestation of the 'disease'. No bladder stones were found in the mink with 'wet-belly disease' on autopsy.

Examination of the urine showed no differences in acidity (pH 6·2 and 6·3) between 'diseased' and normal males. Negative findings were also obtained for the presence of significant amounts of glucose and albumin in urine. Histopathological sections showed no evidence of cystitis, but some kidney damage was present in the kidneys of the 'diseased' mink.

Bacteriological investigation of male mink with active 'wet-belly disease' showed that nine of ten animals examined were infected with *Proteus* organisms in the prepuce cavity, whereas ten normal male mink gave negative findings. Other bacteria of the coliform group, *Staphylococcus*, *Streptococcus fecales* and *Salmonella* organisms were variably present in normal and 'diseased' mink.

The bacterial smears from the prepuce cavities in mink with active 'wet-belly disease' were usually significantly more heavily infected with bacteria than corresponding smears from normal mink or from those which had recovered from the disease. In the latter, coincident with the diminution of contamination by bacteria, there was a significant disappearance of *Proteus* organisms and inflammation.

To determine whether the *Proteus* strains isolated from the prepuce cavity had infected the mink, agglutination tests were carried out with the blood sera of mink which were known to have had 'wet-belly disease' and to have recovered from it. Blood sera from seven of ten of such mink showed significantly high antibody titres (160–1,280) to a strain of *Proteus mirabilis* recovered from the prepuce cavities of the above mink. Conversely, all the sera from the above male mink gave negative agglutination tests to a strain of *Proteus vulgaris* recovered from one of them. As controls, blood sera were taken from six female mink which had received the 'wet-belly'-inducing rations for a period of six months, but which had not developed 'wet-belly' condition. These gave completely negative agglutination tests to the pathogenic strain of *Proteus mirabilis*.

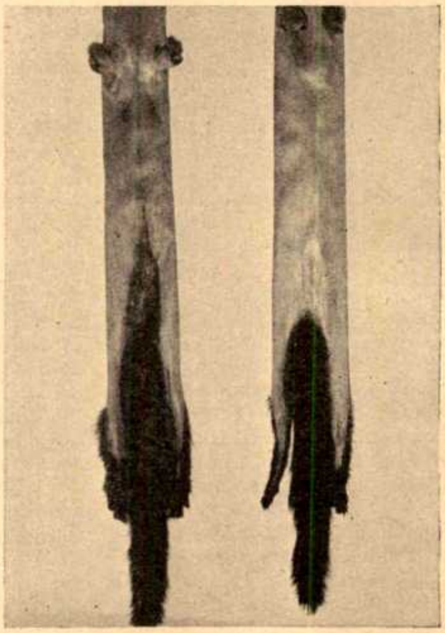

Fig. 2. Left, pigmented leather from wet-belly disease; right, normal leather

To learn the route of transmission of the *Proteus* organisms to the prepuce cavity, a bacteriological examination was made of the fæces of mink that had recovered from 'wet-belly disease'. *Proteus mirabilis* was found in the fæces of these mink, suggesting that the 'disease' originates via the intestinal tract. The fæcal strains of *Proteus mirabilis* gave the same morphological, cultural and biochemical tests and agglutinated to the same titre (with the same mink sera) as the original strain of *Proteus mirabilis* obtained from the prepuce cavities of these male mink.

Further examination was then made of the different meat and fish products of the 'wet-belly'-inducing rations for the presence of these organisms. *Proteus mirabilis* was found to be present in relatively high concentrations in the raw chicken waste, whole fish and tripe used in these rations. Also, it gave the same bacteriological tests, and was agglutinated by the sera taken from the male mink which had recovered from the 'disease'. On the other hand, five different samples of horse meat, which had not caused 'wet-belly disease', gave negative tests for the presence of *Proteus* organisms.

In another experiment, 48 kit mink (24 males and 24 females) were fed the above-mentioned 'wet-belly'-inducing ration (control); a second similar group was fed the same ration, except that the chicken waste, fish and tripe had been cooked; a third similar group was fed the same ration, except that the chicken waste, fish and tripe had been deep frozen to −10° to −20° F.

The incidence of 'wet-belly disease' was decreased 50 per cent by cooking and 44 per cent by freezing, when compared with the number of cases found on the control ration. No cases of 'wet-belly disease' occurred in the 72 females on the experiment.

A further experiment was carried out with 32 male mink kits. These were given a standard horse-meat ration, which could be expected to produce no 'wet-belly disease'. The rations of 16 of these mink were heavily contaminated daily with *Proteus mirabilis* organisms during August–December. 'Wet-belly disease' had occurred by December in eight of the 16 mink receiving the infected feed, but in only one mink of the 16 receiving the same but non-infected ration. Bacteriological smears showed that in 50 per cent of these mink with 'wet-belly disease', *Proteus mirabilis* could be readily recovered from the prepuce cavity.

Because at this Station the onset of visible external symptoms of this disease were not found to occur until the month of November, coincident with the onset of colder weather and furring of the mink, it would therefore appear that these may be stress factors which predispose the mink to infection by lowering their resistance. However, the mink at this Station had been caught and weighed weekly or bi-weekly during a period of 11 years (prior to the feeding of a 'wet-belly'-producing ration which resulted in 40–70 per cent occurrence of the 'disease' in 1960 and 1961) with less than 1 per cent incidence of this 'disease' among kit males.

Although further work is in progress, the experimental findings to date suggest that the 'disease' is a monovalent or polyvalent infection caused by *Proteus* organisms or/and other potential pathogens present in chicken waste, whole fish or tripe. These organisms have been found in high concentrations in such feedstuffs and are thought to infect (under suitable environmental conditions) young growing mink which may have a relatively low resistance to such potential pathogenic bacteria.

IMMUNOLOGICAL PROPERTIES OF PHOTODYNAMICALLY INACTIVATED TUMOUR CELLS

By JUDITH S. BELLIN*

Polytechnic Institute of Brooklyn, Brooklyn, N.Y.

THE oxidation of biological substrates as mediated by the action of visible light and certain dyes has been termed 'photodynamic action'[1]. The photodynamic inactivation of tumour cells results in their inability to produce tumour growth on subsequent transplantation[2]. As an extension of this work it was of interest to inquire whether it is possible to induce an immune state by the inoculation of tumour cells thus attenuated by the action of light and dyes.

In *C3H* mice which have received an injection of viable *6C3HED* tumour cells, and which therefore harbour an actively growing tumour, a challenging dose of the same tumour at a different site is invariably rejected. Such a second-set reaction cannot be demonstrated in *C3H* mice which were originally injected with photodynamically inactivated tumour cells. Table 1 illustrates the results obtained in a representative experiment (for details as to materials and method of procedure see ref. 1). Four groups of twenty male *C3H/Hej* mice were injected subcutaneously on the right side, each with 500,000 *6C3HED* tumour cells. Prior to injection the cells had been treated as shown in Table 1. As expected, the cells which had been illuminated with white light (from a

slide projector) and those which had been treated with dye in the absence of light were viable, and induced tumour growth at the site of injection in all animals. Those cells which had been exposed to both dye and light failed to induce tumour growth, as did similarly treated cells which had been re-suspended in Freund's adjuvant. Thirteen days after the original injection, all the mice received a second implantation, this time on the left side, consisting of 750,000 viable tumour cells. Eight days later only one of the animals in the group harbouring actively growing tumour on the right side had developed additional growths on the left (at autopsy this one growth proved to be an extension of the original tumour), whereas most of the animals which had no primary tumour had developed growths on the left side. The use of Freund's adjuvant did not enable photo-inactivated cells to induce immunity in the host.

Swiss mice which bear sarcoma 180 in the tail are about 60 per cent immune to a challenging dose of viable tumour cells injected a week after the tails have been amputated[3]. This immunity cannot be demonstrated in similarly treated mice which originally received tail injections of photodynamically inactivated tumour cells. Table 2 summarizes data on such an experiment. Ninety Swiss mice (obtained from the pathogen-free colony at the State University of New York, Downstate Medical Center, males and females equally divided among all three groups) were injected subcutaneously in the tail with 0·1 c.c. of a slurry of *S*180 cells, which had previously been treated as indicated in Table 2. Tumours did not develop in the tails of those mice which had received photo-inactivated tumour cells. Eleven days after injection the tails of all animals were amputated, and the stumps were allowed to heal. On day fourteen all mice received 500,000 viable tumour cells intraperitoneally. It can readily be seen that those animals which had received photodynamically inactivated cells were not immune to the challenging injection.

Table 2. IMMUNOLOGICAL PROPERTIES OF SARCOMA 180 CELLS

Day 1	Day 11*	Day 14	Day 64	
Cells injected subcutaneously into tail:	No. tumours in tail	developed ascites	No. mice surviving	Immune (per cent)
Saline, white light 15 min.	23/26	11/26	15/26	59
10^{-5} *M* thionine, dark	24/30	13/30	17/30	57
10^{-5} *M* thionine, white light 15 min.	0/30	30/30	0/30	0

* All tails amputated on day 11; on day 14, 500,000 viable *S*180 cells injected intraperitoneally.

Other workers[4-6] have shown that tumour cells can retain the power to immunize, even though they are no longer capable of progressive growth. Thus sarcoma 180 cells which had been irradiated *in vitro* with moderately heavy doses of X-rays (2,000 r.) could no longer induce tumour growth on transplantation, but conferred immunity to a challenging dose in 95–100 per cent of the animals. When irradiated with doses of 60,000 r. the tumour cells lost this immunizing ability as well[4]. Slightly higher figures were found[5] for achieving comparable effects in the case of a *C3HB* tumour in *C3H* mice. Irradiation for ten minutes with white light from a 500-W. lamp in the presence of 10^{-5} *M* thionine is sufficient to inactivate tumour cells[2]. During this time approximately 30 joules are absorbed per ml. of the suspension. This dose is sufficient to impair both the viability (as shown by lack of tumour growth on transplantation) and the immunizing ability of the cells, and is thus equivalent in action to a dose of 60,000 r. needed to achieve the same result with X-rays.

Tumour cells inactivated by photodynamic means are not able to induce immunity in the host-line in which they originated. This presumably indicates that under the above conditions the photodynamic process produces qualitative changes in the tumour cells which makes them antigenically different from viable tumour cells. It is interesting to note that most of the dyes which cause photodynamic inactivation of tumour cells have a strong affinity to RNA and DNA, and it is tempting to speculate that the photodynamic alteration of the antigenic properties of these cells was specifically mediated by their inactivation of protein-synthesizing systems in the cell. It would be of interest to investigate the (possibly selective) inactivation of the enzyme formation in bacterial cells by selected dyes in order to test this possibility.

These investigations were performed in the laboratory of Dr. S. C. Mohos at the State University of New York, Downstate Medical Centre. I thank him for his helpful suggestions.

A SEX DIFFERENCE IN EFFECT OF TEMPORAL-LOBE NEUROSURGERY ON DESIGN PREFERENCE

By DR. H. LANSDELL

National Institute of Neurological Diseases and Blindness, Bethesda, Maryland

THE human brain has a pronounced asymmetry of function: one hemisphere, generally the left, is clearly 'dominant' for speech[1], and the other is possibly more important for perception[2,3]. The present investigation, part of a project on the psychological changes following temporal-lobe surgery, was concerned with a test of artistic aptitude and the impairment that should occur after removal of cerebral tissue from the non-dominant side. The neurosurgery produced asymmetrical effects of this kind; but, unexpectedly, they were found only in men; the lateralized effects in women were reversed.

Twenty-two patients with temporal-lobe epilepsy were tested on the Graves design judgment test before and again 13–31 (mean 17) days after undergoing unilateral temporal-lobe surgery for the relief of their epilepsy[4]. Forty-two additional cases were tested for the first time 1–8 (mean 4·2) years after such surgery. The age at surgery for the 64 cases was 11–57 (mean 31) years. In one man and two women

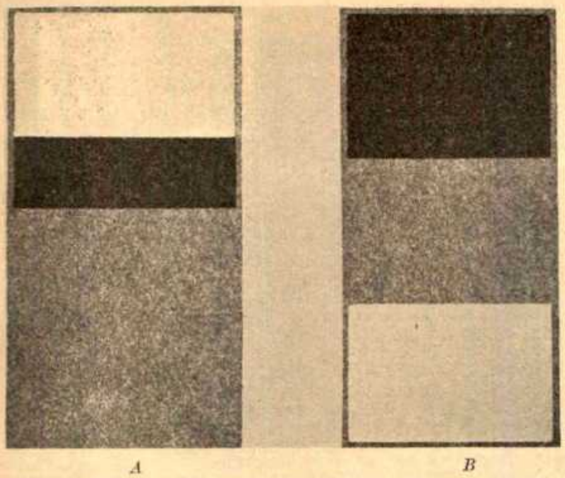

Fig. 1. Representative item (No. 46) from the Graves design judgment test. *A* is the more artistic design

the dominant hemisphere for speech was on the right side according to the 'carotid "Amytal" test'[5]; their operations were on the left. One of these women was in the group tested only after surgery.

The Graves test was designed to measure "certain components of aptitude for the appreciation or production of art structure"[6]. The test consists of 90 items in a booklet; for each item, the subject is required to choose the preferred design from two, occasionally three, printed on a page (an example is shown in Fig. 1). The designs are abstract with little or no 'meaningful' content; the inartistic ones contravene principles of æsthetic order and are often symmetrical designs or nearly so. The only colour used, and not in all items, is a greyish green. Preferences are marked on a standard answer sheet. The test is not timed.

The effect of the surgery on the patients' preferences appeared to be negligible until the sex of the patients was taken into account (Table 1). The group of men with resections in the non-dominant hemisphere showed a drop in mean aptitude score after the operations, whereas the women with non-dominant operations showed a rise. Conversely, with operations in the dominant hemisphere, the men showed a rise in score while the women showed a drop. An analysis of variance showed that this interaction of sex, side and change with operations was significant ($P < 0·01$). Since the rank order of the four means after the operations was the same as before, it might appear that the operations accentuated differences which were already present. However, separate analyses of the pre- and post-operative scores indicated a significant interaction of sex and side only after operation ($P < 0·01$).

Three patients had changes in score which were opposite to the general pattern described, and two patients showed no change. For three of these five cases the atypical nature of the operations seems to be pertinent to their inconsistent behaviour. The ablation on the non-dominant side in a man who showed no change in score was done in two stages nine months apart; his score might have dropped had he been tested after the first stage. The operations on the dominant side in two men who showed a drop in score were also unique: one was performed six days after a simultaneous exploration of both temporal areas, the other was interrupted by a laryngospasm and the brain bulging for a few minutes through the cranial opening. Possibly these operations entailed some disruption of functions on the non-dominant side.

Table 1. PRE- AND POST-OPERATIVE MEAN SCORES ON THE GRAVES TEST

Sex and temporal lobe operated	No. of cases	Pre-operative mean	Post-operative mean
Men, non-dominant	8	35·4	28·0
Women, non-dominant	5	41·8	47·2
Men, dominant	7	41·0	46·9
Women, dominant	2	31·5	26·5

A chance score would be 44; the published means for the test range from 41·0 for 106 non-art high school students to 77·3 for 54 students in their third year in an art school (ref. 6).

The amount of tissue removed in the 22 cases was often less than that usually reported for this type of operation, measuring about 3–5½ cm. from the tip of the lobe on the right and about 2½–4½ cm. on the left, and sometimes gyri or the tip of the lobe were spared. The relation between estimates of the amount removed and the amount of change in scores tended to be inverse although not statistically significant.

The low scores following some of the operations indicate a marked preference for designs which are symmetrical or otherwise too simply structured. These patients could be displaying the concreteness and simplicity in perception often reported in patients with gross brain damage. The better scores after other operations might be a result of the removal of disruptive epileptogenic tissue from the other side. An interpretation of the better scores as a result of practice seems unlikely because no general tendency for improvement was found in nine other cases that had exploratory operations with no removal of tissue.

The changes on the Graves test do not appear to be 'intellectual' in so far as they were not found to be related to changes in the scores on the Wechsler–Bellevue intelligence tests. There was an expected significant drop[2] in the mean of the total weighted scores for the six 'verbal' sub-tests after the operation in the dominant hemisphere ($P < 0·02$, one-tail test).

Although the post-operative changes on the Graves test are clear, they appear to be transitory. No significant relation to the surgery was discernible either for sex or side of operation in the group of 42 patients tested a year or more after their operations. The mean score for the 15 women (42·7) was slightly, but not significantly, higher than the mean for the 27 men (38·2). Furthermore, 11 of the original group of 22 patients have been tested a third time, with a mean lapse of 17 months since their operations. Ten showed a change opposite to that shown on the first post-operative test; three patients who got better scores on their first post-operative test dropped on the third testing, and the other seven dropped, then rose. A woman whose score was unchanged after a non-dominant operation scored lower on the last test. Finally, combining the data from these 11 cases on their third testing with the data from the other 42 cases also yielded no significant differences. That the test still did measure something in the latter group of 53 cases is indicated by a low, but significant, correlation with intelligence ($r = 0·47$).

The results obtained with the women, unlike those with the men, do not conform to the hypothesis that an impairment in some aspect of human visual perception occurs after removals from the temporal lobe of the non-dominant hemisphere. A similar failure of results for women to agree with those for men has been found in an examination of the effect of dominant temporal-lobe operations on an objective test of proverbs: the women were unaffected and the men dropped in score after operation[7]. The varying proportion of women to men in previous investigations may have been partly responsible for the varied success in demonstrating lateralized effect of temporal-lobe surgery[8].

The effects of the operations suggest that some physiological mechanisms underlying artistic judgment and verbal ability may overlap in the female brain but are in opposite hemispheres in the male. Some data in the psychometric literature could be interpreted in the same way: girls show positive correlations between their level of artistic interest and their competence on tests of verbal reasoning and language usage, whereas boys do not[9].

Although the Graves test is considered to be an aptitude test, it is not like the usual speed test which measures efficiency of perception; it is not timed and the subject is not asked to choose 'correct' answers. The Graves test is probably measuring a factor called 'liking for simplicity versus complexity' which has been demonstrated in several experiments on form preferences[10]. Temporary changes in an 'interest' factor as a result of neurosurgery might have been expected. But it is surprising to find that the function of each temporal lobe in regard to this trait appears to be opposite in each sex.

I thank Dr. Maitland Baldwin, clinical director of this Institute, for encouraging psychological research on his patients, and Dr. E. J. Laskowski for supplying the results of the carotid 'Amytal' tests.

NEW RESULTS ABOUT THE MECHANISM OF PHOTOSYNTHESIS

By B. RUMBERG, DR. A. MÜLLER and DR. H. T. WITT

Physikalisch–Chemisches Institut, Universität Marburg

A REACTION scheme of photosynthesis derived from analysis of short-timed absorption changes has already been devised[1-3]. Further flashing light measurements lead to an extended scheme as presented in Fig. 1.

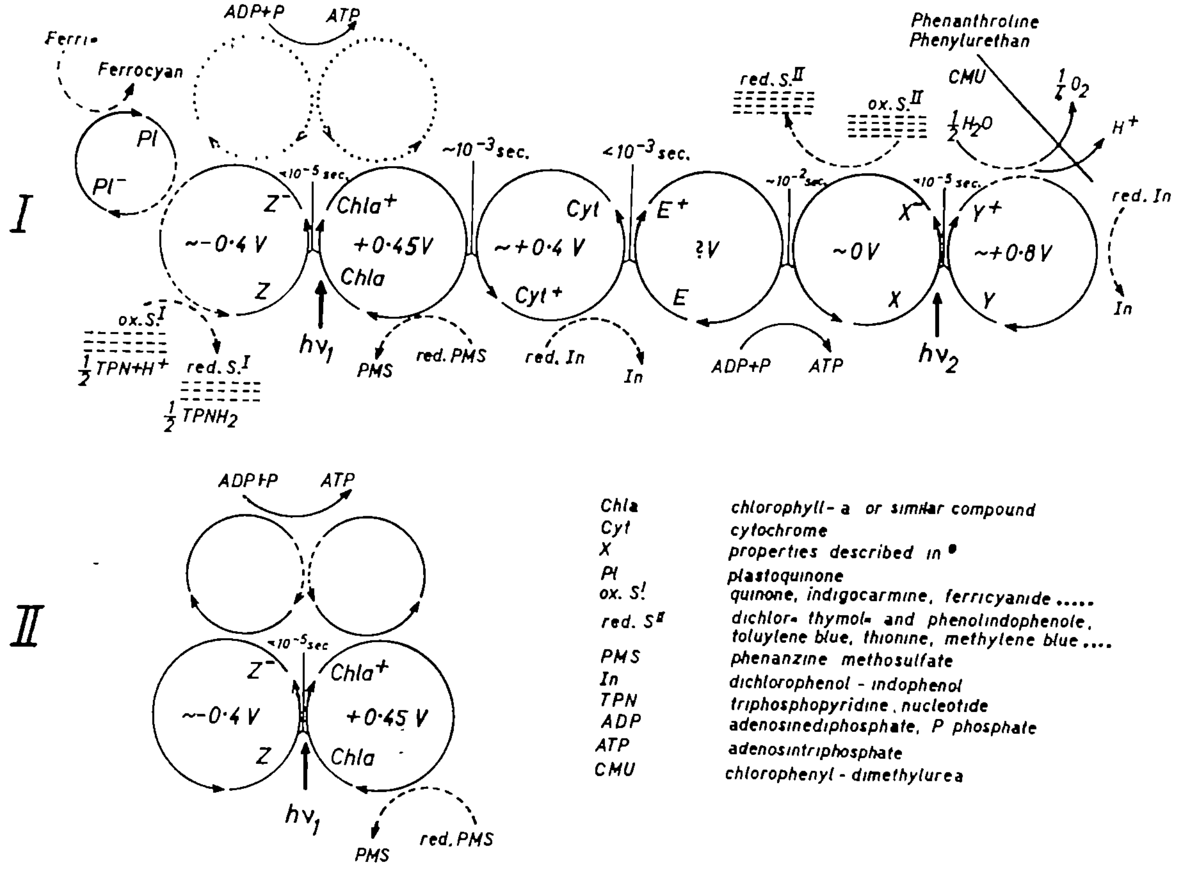
Cytochrome oxidation Cyt → Cyt$^+$ is characterized by changes in absorption around 405, 420 and 555 mμ. In green plants under normal conditions corresponding changes are observable only at 420 mμ. It was supposed that these are caused by cytochrome and that the smaller ones at 405 and 555 mμ are incidentally compensated by changes caused by $X \rightarrow X^-$. Extended measurements between 400 and 700 mμ give no evidence that $X \rightarrow X^-$ causes changes other than those around 475 and 515 mμ. Therefore, the changes at 420 mμ are obviously not caused by cytochrome. However, we found that typical changes (at ~ 405, ~ 420, ~ 555 mμ) caused by Cyt→Cyt$^+$ are always observable when the reduction of Cyt$^+$ is delayed. Such a delay can be caused in different ways: (*a*) By exciting *Chlorella* or chloroplasts only with $h\nu_1$-light (far red). In this case only small amounts of X^- are formed for reduction of Cyt$^+$ (ref. 1). (*b*) By exciting chloroplasts at $-150°$ C. At such temperatures the reduction of Cyt$^+$ is completely stopped[3]. (*c*) By addition of oxidized dichlorophenol-indophenol and small amounts of reduced dichlorophenol-indophenol which uncouple Cyt from X in chloroplasts (see Fig. 1). (*d*) By using aged chloroplasts. In such chloroplasts X and Y are inactive. Added small amounts of red. In or red. PMS ($< 10^{-5}$ M/l) are used as *e*-donor for Cyt$^+$.

Cyt→Cyt$^+$ becomes observable when the reduction time Cyt$^+$→Cyt is delayed more than 10^{-3} sec. This suggests that under normal conditions the reduction time must be shorter than 10^{-3} sec. Then the reduction is faster than the time of oxidation, which was estimated at ~ 10^{-3} sec.[3]. From these figures it is plausible that in normal conditions no accumulation of Cyt$^+$ occurs. (In ref. 1 we reported that Cyt$^+$ is reduced in ~ 10^{-2} sec. This was derived from the kinetics of the changes which appear under normal conditions at 420 mμ and from which we now have to suppose that they are not caused by cytochrome.)

The unknown agent reducing Cyt$^+$ in $< 10^{-3}$ sec. is called *E*. This is reduced directly or indirectly by X^-. As opposed to ref. 3, in Fig. 1 of this article: (*a*) the experimentally estimated redox-potential of cytochrome[1] is depicted; (*b*) *Chla* is used instead of *C*.

Bishop[4] has shown that plastoquinone *Pl* has a function in the *e*-transport during photosynthesis. From the changes in absorption in the ultra-violet[5] we have to assume that *Pl* is at least engaged as an *e*-acceptor of Z^- (Fig. 2). But from the redox potential of X and the reversible extraction experiments with petroleum ether[1] another part of *Pl* seems to be engaged with the reaction of X.

In ref. 3 it was shown that the light-induced changes in absorption at 430 and 703 mμ[3,6] are caused by one and the same substance—by photo-oxidation of a chlorophyll *a* or a similar compound (*Chla* → *Chla*$^+$)—because both changes show identical kinetic behaviour. These investigations were extended. Different *p*H values (2–12), temperatures (5–35° C.), and concentrations of added reduced phenazine methosulphate (10^{-6}–10^{-4} M/l.) exert a strong influence on the decay time or magnitude of the changes; but in any event the behaviour at 430 mμ is exactly the same as at 703 mμ. Detailed analysis of the changes at 430 and 703 mμ by one of us (B. R.) shows that these changes are caused by photo-oxidation of *Chla* in two completely different reaction systems I and II (Fig. 1). This means that at least three different light reactions are engaged in photosynthesis. 50 per cent of *Chla* is engaged in the non-cyclic electron transport of system I; the other 50 per cent of *Chla* reacts in system II, which probably operates only by cyclic electron transport. This can be shown in the following way.



Chla	*chlorophyll-a or similar compound*
Cyt	*cytochrome*
X	*properties described in* ●
Pl	*plastoquinone*
ox. S.I	*quinone, indigocarmine, ferricyanide .....*
red. S.II	*dichlor- thymol- and phenolindophenole,* *toluylene blue, thionine, methylene blue ....*
PMS	*phenanzine methosulfate*
In	*dichlorophenol - indophenol*
TPN	*triphosphopyridine, nucleotide*
ADP	*adenosinediphosphate, P phosphate*
ATP	*adenosintriphosphate*
CMU	*chlorophenyl - dimethylurea*

Fig. 1. Reaction pattern in photosynthesis at 20° C. ●, Witt, H. T., and Muller, A., *Z. phys. Chem.*, *N.F.*, 21, 1 (1959). Cyt^+ can react also with red. PMS. At higher concentrations (≮ 10^{-5} μ/c.) red. PMS by-passes Cyt^+ and reacts with $Chla^+$

By exciting with flashing light the 50 per cent *Chla* in I as well as the 50 per cent *Chla* in II are oxidized and afterwards reduced (causing negative changes at 703 mμ, see *a* in Fig. 2). By using continuous background illumination of low intensity with only $h\nu_1$-light (708 mμ), the 50 per cent of *Chla* in system I, Cyt and *E* should be enriched in oxidized form because nearly no X^- is produced for its reduction. Vice versa, the other 50 per cent *Chla* in system II should not be enriched at low intensity because of the cyclic *e*-transport. Therefore, the $h\nu_1$-light of a supplementary flash (with $h\nu_1$- and $h\nu_2$-lights) can oxidize only the 50 per cent *Chla* in system II with following reduction (*b* in Fig. 2). The $h\nu_2$-light of the same flash produces X^- (causing changes at 515 mμ (see *c* in Fig. 2)). X^- should reduce the 50 per cent *Chla* in system I, already oxidized by the continuous background light, via Cyt and *E*. This can be followed by the *positive* changes at 703 mμ (*d* in Fig. 2)[7].

The simultaneous oxidation of X^- can be followed at 515 mμ (*e* in Fig. 2). The rate-determining step for the reduction of already oxidized $Chla^+$, via E^+ and Cyt^+, is given by the oxidation time of X^- ($\sim 10^{-2}$ sec.). Therefore, the time dependence of the changes at 515 mμ and of the *positive* ones at 703 mμ should be the same (compare *d* and *e* in Fig. 2). Different conditions such as different *p*H (6–8), temperatures (0–35° C.) or ageing (0–7 days) have strong influence

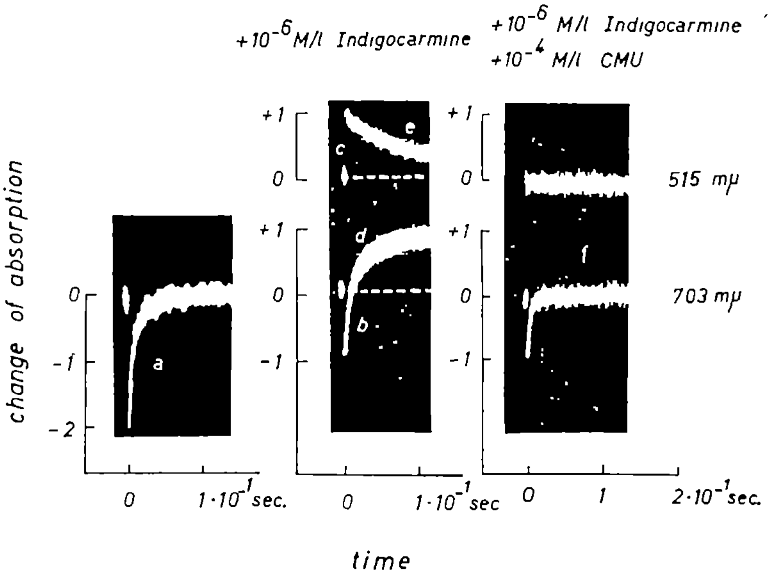


Fig. 2. Relative changes of absorption on chloroplasts (spinach) caused by a flash of light. 20° C., *p*H = 7. The flash was turned on at *t* = 0; flash duration = 10^{-4} sec.

on the changes at 515 mμ (*e*) and the positive ones at 703 mμ (*d*). But in any event the influence is—as expected—exactly the same at both wave-lengths. This shows quantitatively the co-operation of *Chla* and X via Cyt and E in system I. Comparing the positive changes of *Chla* in I with the negative ones of *Chla* in II (*d* and *b* in Fig. 2) in dependence of poisons or ageing (0–7 days) or *p*H (6–8) it results for both a quite different dependency. This confirms that the *Chla*-reactions operate in two different systems, I and II. For example, chlorophenyl dimethylurea (CMU) stops non-cyclic *e*-transport by blocking oxygen production. Therefore, addition of chlorophenyl dimethylurea should stop all reactions of system I but none in system II because of the cyclic *e*-transport in II. Fig. 2*f* shows the result. As expected, there remain only the negative changes caused by the 50 per cent of *Chla* operating in system II. (With high concentrations of chlorophenyl dimethylurea, $\geqslant 10^{-3}$ *M*/l., as used in ref. 3, all changes vanish.)

Further analysis shows that also in system I a cyclic *e*-transport is possible: $\overset{\longrightarrow}{Z \leftarrow \mathit{Chla}}$. But while the probably only cyclic *e*-transport in II is always operating, cyclic *e*-transport in I is only possible when no *e*-acceptor, ox.S.$^{\mathrm{I}}$ (Fig. 1) or *Pl* (Fig. 1) is available for Z^- in system I. We found out that in chloroplasts oxidized indigocarmine, quinone and ferricyanide are compounds which react with Z^- preventing cyclic *e*-transport in system I (in the experiments of Fig. 2 oxidized indigocarmine was used). Further evidence for the probability of the scheme in Fig. 1 is given by the separation of the mechanism into seven partial reactions (see ref. 10).

From the redox potentials it follows that phosphorylation[8] (ADP + P → ATP) can be coupled with reactions as indicated in Fig. 1. A non-cyclic phosphorylation can take place in system I between Cyt and E or E and X. It may be that the function of system II is to generate a cyclic phosphorylation. With ATP and $TPNH_2$ carbon dioxide can be reduced to sugar via the Calvin cycle[9].

DIGITAL COMPUTER SIMULATION OF ECOLOGICAL SYSTEMS

By Dr. DAVID GARFINKEL

Johnson Research Foundation, University of Pennsylvania, Philadelphia, 4

THE mathematical representation of ecological systems has been investigated for several decades, starting with the pioneer work of Volterra[1] and Lotka[2]. Most of this work has been done with pencil and paper and has necessarily been limited to systems simple enough to permit the analytical solution of the resulting equations. Some work has been done with analogue computers[3], and an application of digital computers to the problem has been made by Watt[4,5]. It is the purpose of this article to describe a general computer method of representing ecological systems of any desired degree of complexity in terms of simultaneous first-order differential equations, with some simple illustrative applications.

The calculations thus far performed are based on the assumption[1,2,6] that the rate at which two species interact is proportional to the product of their numbers. This rate law is identical to the mass action law of chemistry and therefore permits the use of a computer programme[7,8] developed to represent complex chemical systems with the *Univac I* computer. This programme enables the computer, when given as input a set of chemical equations of the form:

$$A + B \rightarrow C + D$$

automatically to write instructions to solve the associated set of differential equations:

$$-\frac{\mathrm{d}A}{\mathrm{d}t} = -\frac{\mathrm{d}B}{\mathrm{d}t} = k\,(A)\,(B)$$

and then perform the solution by numerical methods when given a set of initial conditions. It is possible to write and solve sets of equations having no relationship to chemistry, and it would be possible to substitute some other interaction law for the mass action law, or to make allowance for its limitations[5].

The system examined here (represented by the 'chemical' and differential equations shown in Table 1) consists of a prey, grass (*GRS*), and a predator, rabbits, which may be either adequately fed (*FRB*) or starved (*SRB*). The starved rabbits are assumed to die at a moderately rapid rate if unable to feed; the fed ones, to reproduce. In most of the calculations, it has been assumed that some of the grass is segregated in such a way that the rabbits cannot get at it (that is, roots

Table 1

'Chemical' equations	Rate constants
(1) $GRS \rightarrow GRS$	$k_1 = 24$
(2) $SRB + GRS \rightarrow FRB - SRB - GRS^{a}$	k_2 varied $\begin{cases} 3 \times 10^{-1} \\ 10^{-3} \end{cases}$
(3) $FRB \rightarrow FRB$	$k_3 = 30$
(4) $FRB \rightarrow SRB - FRB$	$k_4 = 300$
(5) $SRB \rightarrow DUM - SRB^{b}$	$k_5 = 33$
(6) $FRB \rightarrow DUM - FRB$	$k_6 = 3$
(7) $FRB + GRS \rightarrow DUM - GRS^{c}$	$k_7 = 0\,012$
(8) $RTS \rightarrow GRS^{d}$	$k_8 = 5 \times 10^{-4}$
(9) $GRS + GRS \rightarrow DUM - GRS^{e}$	$k_9 = 5 \times 10^{-5}$

Corresponding differential equations

$$\frac{\mathrm{d}(GRS)}{\mathrm{d}t} = k_8(RTS) + k_1(GRS) - k_9(GRS)^2 - k_7(FRB)(GRS) - k_2(SRB)(GRS)$$

$$\frac{\mathrm{d}(SRB)}{\mathrm{d}t} = k_4(FRB) - k_5(SRB) - k_2(GRS)(SRB)$$

$$\frac{\mathrm{d}(FRB)}{\mathrm{d}t} = k_3(FRB) + k_2(GRS)(SRB) - k_6(FRB) - k_4(FRB)$$

a, Substances which disappear in a reaction must be listed again on the right side of the equation.

b, This statement is equivalent to '*SRB* disappears'.

c, Fed rabbits continue to eat.

d, *RTS* = roots To abolish the roots, k_8 is set equal to zero.

e, This is to limit the amount of grass that may grow in a fixed land area which they cannot dig up), which is equivalent to a constant influx of grass into the system.

Varying the predative efficiency of the starved rabbits yields results shown in Figs. 1–4. If the rabbits are highly efficient predators with access to all the grass, they will exterminate it and then starve to death (Fig. 1), a situation observed experimentally by Gause[9]. If some of the grass is inaccessible, a steady state results in which the grass is eaten as fast as it appears (Fig. 2). As the predative efficiency of the rabbits is decreased the system goes into an oscillation (Fig. 3) and then a damped oscillation (Fig. 4). An even more inefficient predator effectively starves to death in the midst of plenty.

A given predator may attack more than one prey organism with differing degrees of efficiency[6]. In many cases this may stabilize the system, but it need not do so: when the predators of Fig. 3 were given an alternative prey, which they attacked less efficiently, they first ate approximately all the available preferred prey, and then came to a steady state with the alternative prey.

In an attempt to duplicate a system where a stable predator–prey relationship may be upset with drastic consequences by adding another predator[10], a second predator (foxes) which eats the rabbits was introduced; the foxes are assumed to reproduce (and die of starvation) more slowly than the rabbits. When foxes were introduced into a system (Fig. 4) which would otherwise come to a steady state, it went into wild oscillations (Fig. 5); at the end of the second oscillation the rabbits were approximately extinct.

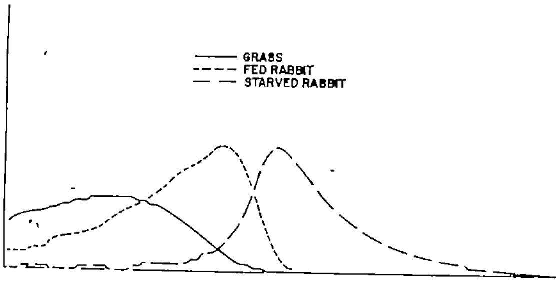

Fig. 1. No. of animals as a function of time with $K_2 = 0·3$ and $K_3 = 0$

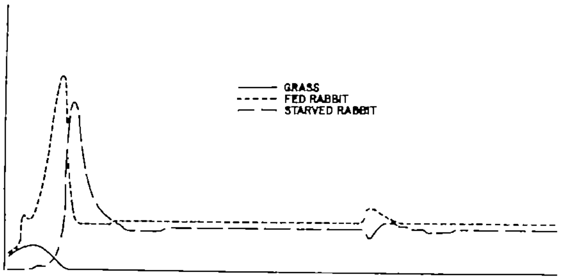

Fig. 2. No. of animals as a function of time with $K_2 = 0·3$ and $K_3 = 0·24$

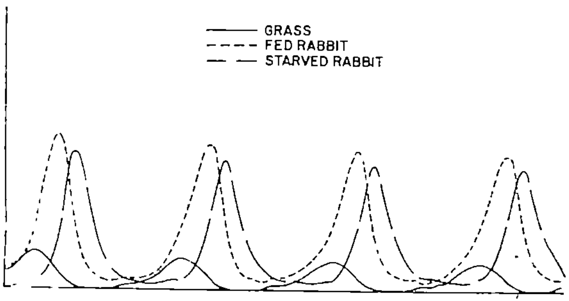

Fig. 3. No. of animals as a function of time with $K_2 = 5 \times 10^{-3}$ and $K_3 = 0·24$

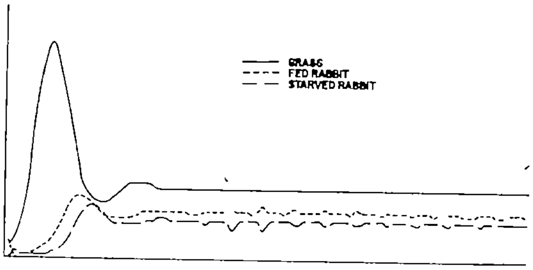

Fig 4 No of animals as a function of time with $K_2 = 10^{-2}$ and $K_3 = 0·24$

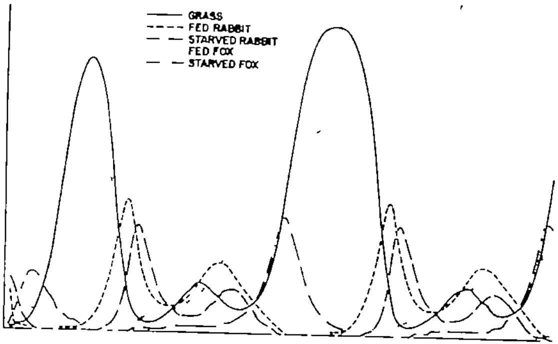

Fig. 5. No. of animals as a function of time with foxes introduced into the system of Fig. 4

Application of this method calculation to ecological problems offers two distinct advantages: (1) The computer can be made to deal with nearly all the mathematics. (2) The limit of complexity is that imposed by the speed and memory size of the computer used (the largest now in existence would be able to handle more than 1,000 species in this manner). By suitably defining new 'species' and taking advantage of other properties of the programme, it is possible to represent environmental variations, disease, different states of nutrition, effect of age, etc.

This method of calculation can be applied both to studies in theoretical ecology and to real situations (such as agricultural pest control). It must, however, be emphasized that the ability to perform calculations in this manner is no substitute for detailed knowledge of the system being studied.

This work was performed during the tenure of a Research Career Development Fellowship, U.S. Public Health Service, and supported by the Office of Naval Research.

PHYSICS

Ignition of Gas Mixtures by Electric Discharges between a Heated and a Cold Electrode : Application in Breakflash Apparatus for Intrinsic Safety Testing

THE thermal theory of ignition of gases explains certain phenomena in the ignition of explosive mixtures by electric sparks involving capacitive and break or make discharges. However, a number of important questions for theory as well as practice remain to be answered. In this connexion the author has made some introductory investigations on the ignition of explosive gas mixtures having in mind the simplified assumption that the ignition process is essentially thermal in character, so that some critical temperature is involved in the initiation of the ignition. This temperature may be attained by a single process, such as the heating of a wire, or by more than one process, for example, the heating of a wire plus an electric discharge. In the case of an 8·3 per cent methane–air mixture the initiation of ignition involves a certain critical volume of gas attaining a minimum temperature.

Normally, a considerable proportion of the spark energy is lost in heating the electrodes, though in certain circumstances, for example, capacitance sparks between electrodes at a suitable separation, the loss to the electrodes may be made small. It has been found experimentally that a variety of factors influence the probability of ignition by the break discharge of a given circuit. It appears that these factors affect in various ways the dissipation and utilization of energy in the discharge so that they may increase or decrease the 'incendivity' of the break discharge. These considerations led me to the conclusion that a useful control of the break discharge energy for ignition might be achieved by conducting discharges between a heated and a cold electrode.

The ignition investigations were carried out in a cylindrical chamber of transparent 'Perspex' containing an 8·3 per cent by volume methane–air mixture at atmospheric pressure. The electrode assembly consisted of a stationary heated nichrome wire (80/20 nickel–chromium) of diameter 0·213 mm. (35 S.W.G.), in the shape of a rounded W, and within the middle loop a cold springy wire of tungsten, 0·152 mm. diameter (38 S.W.G.), was arranged to slide and to provide the circuit break. The tungsten wire electrode was driven at a constant speed of 20 r.p.m., so that it passed the heated electrode at a linear speed of about 6 cm./sec.

The preliminary experiments included ignition of the explosive methane–air mixture by (*a*) a heated nichrome electrode alone; (*b*) break discharges from a circuit containing 95 mH. air-cored inductance and a 24-V. d.c. source; (*c*) break discharges from a circuit of very low inductance, also using a 24-V. d.c. source. Further, some observations were made on the behaviour of a cold and hot platinum wire electrode in break discharges.

The experiments completed so far indicate that: (1) The explosive ignition of a methane–air mixture by a heated nichrome electrode alone could be obtained for a few times before the electrode broke. A rapid rise of the electrode temperature gave a high probability of ignition.

(2) The break discharge energy for ignition at a heated electrode decreases as the electrode temperature is increased towards the gas ignition temperature. In Fig. 1 are shown typical ignition probability curves obtained with the inductive circuit at various electrode temperatures (I_h = electrode heating current).

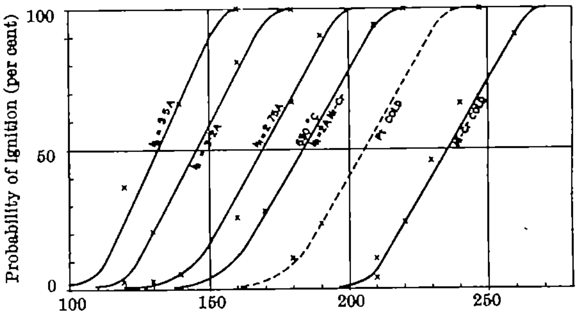

Fig 1

(3) A small number of tests with a circuit of low inductance showed ignitions at break discharges of circuit carrying 1·3 amp. at 24-V. d.c. with electrode heated to about 800° C.

Inductive break discharges between cold platinum wire of 0·274 mm. diameter (32 S.W.G.) and cold moving tungsten wire showed a higher 'incendivity' than that of cold nickel–chromium wire (Fig. 1). This might be attributed to catalytic activity at the surface of the platinum wire. In contrast to this, similar discharges between hot platinum wire showed lower probability of ignition. For a 250 m.amp. circuit current, which produced 100 per cent ignition with cold platinum–tungsten electrodes (Fig. 1), the hot platinum electrode produced only 5 ignitions in 100 tests.

Experiments with electric break (or make) discharges between a heated and cold electrode (or both electrodes might be heated) may yield some information on various aspects of the ignition process, and prove useful in some practical applications. So far, some tentative conclusions can be drawn from the experiments carried out.

(1) The experiments show that electrical break discharges in explosive atmospheres when assisted by appreciable circuit current heating at the point of discharge may create dangerous conditions with currents which are recognized as safe for discharges at cold electrodes.

(2) Operation of a breakflash apparatus with one electrode (or both) heated offers the possibility of an intrinsic safety testing system with high sensitivity (very small igniting currents). The use of a continuously variable heating current in an electrode may enable the safety margins of circuits to be

determined in cases where the application of an over-voltage or an over-current is inconvenient.

γ-Spectrometry compensated for the Compton Effect

PEIRSON *et al.*[1-3] proposed an efficient technique for obtaining net photopeaks in γ-spectrometry by subtracting the Compton continuum of the NaI(Tl) detector by means of an anthracene scintillator. The photoelectric effect in the latter is indeed negligible and gives rise to the Compton effect only. After equalization for pulse height and counting-rate, net photopeaks are thus obtained.

To minimize counting losses, the detection efficiency of both detectors, in the Compton region, should be approximately the same. This requires equal diameters of the scintillators. The cost of the anthracene detector thus becomes quite high when large NaI(Tl) crystals are used. It appeared, however, that a plastic scintillator (Nuclear Enterprises *NE* 102) is equally suitable for this purpose, resulting in a detector cost reduction by a factor of approximately 50.

The detection efficiency of this plastic is about 60 per cent in comparison with the anthracene, whereas the pulse height is about 67 per cent.

Uncompensated and compensated spectra of cobalt-60, using a 3 in. × 3 in. NaI(Tl) and 3 in. × ½ in. anthracene crystal or a 3 in. × ½ in. *NE* 102 plastic scintillator, are given in Fig. 1. From this it appears that an even better compensation for the Compton edge is obtained with the latter. For the spectrum compensated with the plastic scintillator, the detectors were at an angle of 90° and mounted in lead collimators.

When mounted at an angle of 180°, the back scatter is indeed still quite important and extends up to the 500-KeV. region, whereas at an angle of 90° a reduction in back scatter by a factor 3 is obtained.

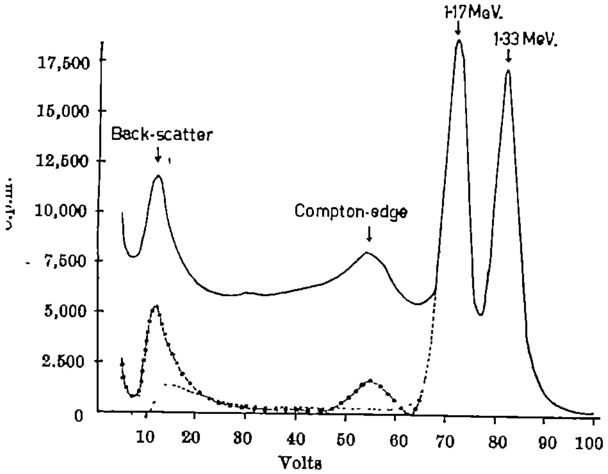

Fig. 1. Spectrum of cobalt-60. ——, Uncompensated (180° angle); –○–, compensated with anthracene (180° angle); - - - -, compensated with plastic scintillator (90° angle and collimator)

The detection efficiency, caused by the lead collimator, is reduced by 20 per cent only.

This technique appeared to be more efficient than the use of a lead absorber before the anthracene crystal as recommended by Peirson *et al.*[4].

GEOLOGY

Age of Deglaciation in the Ruwenzori Range, Uganda

THE massive fault-block of the Ruwenzori Mountains, which lies on the axis of the Western Rift between Uganda and the Congo, is the wettest of the high mountain areas in East Africa. For that reason it has more glaciers at present and has been more extensively glaciated in the past than any of the other tropical African mountains. Although relative ages have been estimated[1,2], no absolute dates have been published for prehistoric glacial events in this or any other tropical African mountain area.

During July of 1960 Mr. Jonathan Richardson, Mr. Robert Kendall and I collected cores from the sediment that had accumulated in glacial lakes at a variety of altitudes on the Uganda side of the Ruwenzori Range. Much of the sediment was fossiliferous and organic enough to permit radiocarbon dating, and an analysis of one sample by Isotopes, Inc., of Westwood, New Jersey, has provided the first absolute date of a major glacial event in East Africa.

The lowest Ruwenzori moraines are in the Mobuku Valley, where they extend down to 2,100 m. near Ibanda. Lateral moraines at slightly higher altitudes occupy the smaller valleys of the mountains. All these moraines are several orders of magnitude larger than any between them and the present glacier termini. Presumably they have been built up during several glaciations; but good exposures are rare and no evidence of interglacial episodes has come to light.

No lakes are to be found close to the lower ends of the low moraines, but one does lie at the junction of the Mobuku River lateral moraine system with that of its principal tributary, the Bujuku River. This is Mahoma Lake (lat. 0° 21′ N., long. 29° 58′ E.) at an altitude of 3,000 m. Its shape, size, depth and relation to the associated moraines all suggest that it occupies a kettle and there is no evidence of a glacial still-stand between it and the lowest moraines in the valley.

We raised a core almost 6 m. long from the mud under 9·5 m. of water in Mahoma Lake. The drilling operation ceased when the borer entered sandy gravel with pieces of stone more than 4 cm. in diameter and the section appeared to be complete. The lowest 0·4 m. of sediment consisted of coarsely graded grey clay, silt and fine sand. The change to organic sediment began rather sharply at a depth of 5·4 m. and was complete within 0·2 m. The organic lake mud consisted very largely of algal remains and was uniform in gross appearance to the top of the section.

The grey inorganic material looks as if it had been laid down very rapidly while the glacier was still close enough to provide a rich source of fine inorganic sediment, so the carbon date of 14,700 ± 290 years B.P. for sample I–556, which came from the bottom 0·2 m. of organic lake mud, should provide a minimum date that is very close to the true date of deglaciation of the locality. This is the first piece of direct evidence to show that fifteen thousand years ago, while the Wurm glacier in Europe and the Wisconsin glacier in America were going through a halting retreat from their southern limits, the equatorial African mountain glaciers were retreating as well. It strongly supports palynological studies (Martin, P., personal communication, and refs. 3 and 4) indicating that Pleistocene climatic changes in the tropics have been of the same sign as those in the rest of the world and synchronous with them.

I thank the John Simon Guggenheim Memorial Foundation and the National Science Foundation for financial support for this work.

Palygorskite in Leicestershire

CURRENT geological investigations into the ancient rocks of Leicestershire have revealed three occurrences of the clay mineral palygorskite. These are in the lower quarry at Bardon Hill, the Cliffe Hill quarry and the Warren quarry at Enderby. At all three localities the palygorskite is present in joints in dioritic rocks. In every case its identification has been checked by X-ray powder techniques. No sepiolite lines were detected on any of the powder photographs.

At Bardon Hill the palygorskite is found as compact, fibrous masses filling the centre of a joint, the walls of which are lined with coarse calcite crystals. At Cliffe Hill and in a deeply penetrating joint at Enderby, the mineral forms fine specimens of mountain leather and in both cases is intergrown with fine-grained calcite. Elsewhere in the Warren quarry at Enderby palygorskite is almost ubiquitous on the joint surfaces of the upper level, where it is free from carbonate impurities and again takes the form of compact, fibrous masses. At all three localities the palygorskite occurs at levels not far below the overlying Triassic unconformity and in the Warren quarry it can be traced, without a break, from the joints in the diorite into the matrix of the overlying basal Triassic breccia.

Palygorskites found in igneous rocks (usually in joints or crush bands) are generally considered to be of hydrothermal origin[1,2]. When found in sediments the mineral is assumed to be of sedimentary origin[3,4]. So far as the Leicestershire localities are concerned the geological similarities of the three occurrences suggest that the palygorskite in each is of the same age and origin. With regard to the origin, the palygorskite at Enderby cannot have been deposited from a hydrothermal differentiate of the dioritic magma since it is found in the overlying Triassic rocks. We believe that it was deposited from downward-moving waters which were in direct connexion with the lakes and rivers in which the basal Triassic sediments of the area were deposited and not from post-Triassic ascending hydrothermal solutions.

The following observations at Enderby are in agreement with this conclusion. (1) Palygorskite is only found on the second (deeper) level in strong joints which persist upwards to the Triassic unconformity. (2) Its main development is in joints within approximately thirty feet of the unconformity. (3) The mineral is most abundant in the area below wadies. (4) It is poorly developed in, or absent from, adjacent, buried hills which would have acted as anticlinal traps for ascending solutions. It is of interest to note here that in Charnwood Forest a number of other mineral veins with calcite, barytes and clay minerals occur in joints in the Charnian rocks. These can be traced upwards into Triassic sediments where the minerals concerned form parts of the matrices of the basal breccias.

In view of this conclusion, we suggest that occurrences of palygorskite in the joints of igneous rocks should not, without supporting evidence, be assumed to be of hydrothermal origin. Further, having noted that palygorskite is frequently reported from continental deposits and soils (often red)[3,5-7], we propose that occurrences such as those in the Shetland Isles[2] and some of the others reported from various parts of Scotland[8] may point to the former existence of Old Red Sandstone or Triassic unconformities at no great height above the points at which palygorskite is now found.

Geochemical Characteristics of Carbonatites

THE lava from Fort Portal in western Uganda, recently described by von Knorring and Du Bois[1], was considered to be carbonatitic in view of the high carbonate content and its agreement with the characteristic trace element pattern as observed among true carbonatites, which are in the main calcitic or dolomitic rocks. In pure carbonatite rocks, significant elements like iron, titanium, zirconium and niobium may be accidental or regional to some degree, whereas elements like strontium, barium, rare earths and phosphorus seem to belong to the earlier (primary) constituents of carbonatite magmas.

An examination of another carbonatite lava, collected from the crater of Oldonyo Lengai volcano in Tanganyika by Dr. N. J. Guest, shows a remarkable composition which may correspond more closely to some of the primary carbonatite magmas. Chemically this lava is composed of sodium, calcium and potassium as major constituents, chlorine, fluorine, sulphur, phosphorus, strontium, barium, manganese and iron as minor, whereas other elements are present in amounts less than 1,000 p.p.m. When finely crushed, about 67 per cent of this lava is soluble in hot water and an X-ray examination showed that the soluble part consists mainly of sodium carbonate and the insoluble of calcium carbonate. The powdered lava melts at approximately 650° C.

Archæocyathine Limestones of Antarctica

ONE of the problems in antarctic geology has been the uncertain stratigraphic position of the Cambrian Archæocyathid limestone found as erratics on the Beardmore Glacier[1,2] and dredged from the Weddell Sea[3]. Probably the Beardmore erratics came from the Mt. Buckley limestone at the head of the glacier; but the field relationships of this limestone are uncertain. In recent syntheses by Fairbridge[4] and Harrington[5] the limestone is left in an uncertain position between the flat-lying Beacon Sandstone, and the underlying steeply dipping Ross System of Harrington. The Beacon Sandstone has yielded upper Palæozoic and Mesozoic fossils, and the Ross System is usually considered pre-Cambrian.

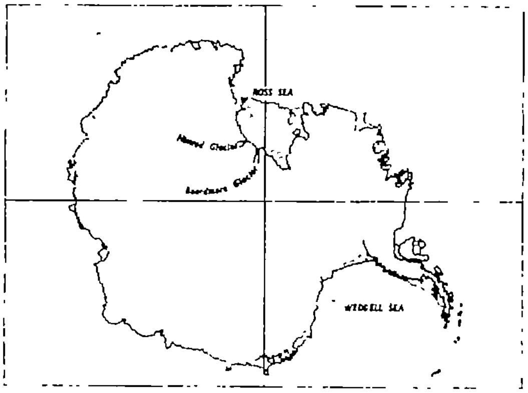

Fig. 1. Locality map of Antarctica

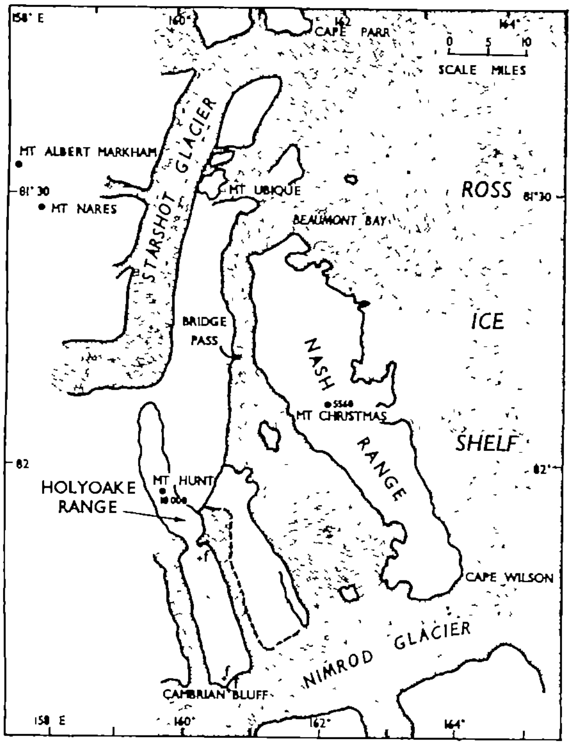

Fig. 2. The Nimrod glacier area, showing fossil localities in Cambrian limestone

Field work during 1960–61 by a New Zealand Geological Survey team suggests that the Archæocyathid limestones belong to the top of the Ross System. Specimens of Archæocyatha were found in place near the Nimrod Glacier in the Holyoake Range (Figs. 1, 2) at three localities, 82° 25′ S., 160° 40′ E.; 82° 23′ 27″ S., 160° 36′ 30″ E.; and 82° 11′ 35″ S., 160° 18′ E. From preliminary examination the fossils belong to several genera of Archaeocyatha, chiefly in the families Coscinocyathidæ and Archaeocyathidæ. They occur in steeply dipping, locally folded, recrystallized and partly recrystallized limestones. The limestones are presumed to overlie greywackes of the Nash Range, which have a similar strike and also dip steeply. These are invaded by plutonic rocks, and clearly belong to the Ross System. An unconformable contact between horizontal Beacon sediments and almost vertical limestone was seen on Mt. Hunt from a distance of six miles. Thus the Cambrian limestones agree with the Ross System in their steep attitude, high degree of folding and partial recrystallization and differ from the flat-lying unmetamorphosed Beacon Sandstone. The Cambrian limestones are therefore assigned to the Ross system, which evidently extends into the Lower Palæozoic.

METEOROLOGY

A Trend Towards a Longer Dry Season in South-western Nigeria

STEBBING[1] has stated that the climate of West Africa was becoming increasingly drier, and that the Sahara was advancing southwards at an alarming rate. The ensuing controversy, which developed in the late 1930's, has been summarized by Jones[2]. During the past 50 or 100 years there has been a distinct degeneration of the vegetation in many parts of West Africa; but most workers considered this to be caused by human activity rather than by a change in climate and pointed out that there was no meteorological evidence for a progressive, rather than a cyclical, climatic change.

The Olokemeji Forest Reserve, in south-western Nigeria, lies across the forest/derived savanna boundary. The general features and vegetation of the reserve have been described[3], and the seasonal changes in the environment are being analysed in order to compare them with the seasonal changes observed in the vegetation. The rainfall data, in particular, are being analysed in some detail. Records are available from 1906 until 1927 and from 1953 to the present day. The mean annual rainfall is 1,232 mm., and no evidence has been found for a progressive change in this value.

The northern climatic limits of the vegetation zones in West Africa depend on the severity of the dry season rather than on the mean annual rainfall. Consequently, the length (in days) of the rainless periods and, in particular, of the maximum dry period during each dry season (November–February) were analysed. This showed that there was a significant positive correlation between the year of the dry season and the length of its maximum dry period ($r = 0{\cdot}43$, $p =$ about 0·02). In calculating the regression, it was found that the maximum dry period was increasing by 0·59 day per year. (For the dry seasons 1953–54 to 1961–62 the mean length of the maximum dry period was 78·1 days.)

Similarly, calculations were carried out on the length of the maximum dry period during the 'little dry season', which occurs about August. Here also there was a significant positive correlation between the year of the 'little dry season' and the length of its maximum dry period ($r = 0{\cdot}53$, $P < 0{\cdot}01$), and the maximum dry period was found to be increasing by 0·23 day per year. (For the 'little dry seasons' 1954–61 the mean length of the maximum dry period was 19·6 days.)

The evidence presented here, although statistically significant, is from only one station, and it is obviously unwise for too far-reaching a conclusion to be drawn from it. Nevertheless, the analysis of records from other stations may show a similar trend towards an increase in the length of the maximum dry period even though, as at Olokemeji, there is no significant change in the annual rainfall. As dry season severity is more important than mean annual rainfall in determining the distribution of the vegetation zones and the consequent land use policy it is important that records from other stations should be analysed for this factor.

BIOPHYSICS

Adsorption of Proteins on 'Sephadex'

IN the course of studies on the gel filtration of a number of proteins on 'Sephadex *G*–50' (trade name for a cross-linked polysaccharide dextran made by Pharmacia, Uppsala, Sweden, who publish a booklet containing an extensive bibliography), it was found that in the absence of salts some proteins were strongly adsorbed to the gel. For example, ribonuclease, lysozyme, trypsin, bovine serum albumin and a polytyrosyl derivative of trypsin[1] were all adsorbed and could not be removed by extensive washing with distilled water. However, these proteins were recovered quantitatively by elution with dilute sodium chloride solutions. Since 'Sephadex' has been used extensively for the desalting of protein solutions and for the separation of proteins from materials of low molecular weight, it is important to note that in attempts to remove salts completely by using distilled water as eluant, this phenomenon may lead to complications.

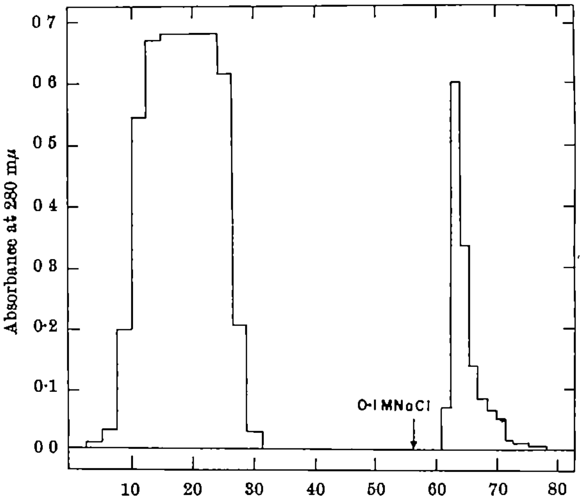

Fig. 1. Adsorption of ribonuclease on 'Sephadex *G*-50' and elution with 0·1 *M* sodium chloride. 20 ml. of ribonuclease solution (1 mgm./ml.) was passed through the column (8·5 cm. × 1·2 cm.), followed by water and 0·1 *M* sodium chloride (arrow)

Two batches of 'Sephadex *G*–50' were used in this work. (The manufacturer's specifications for the 'Sephadex *G*–50' were as follows: "Lot No. To 6809, Dry screen analysis: On U.S. No. 50 0·0 per cent, Through U.S. No. 270 3·3 per cent, Water regain, 4·7 gm. water per gm. dry gel; Lot No. To 6387, Dry screen analysis: On U.S. No. 50 0·1 per cent, Through U.S. No. 270 0·6 per cent, Water regain, 5·0 gm. water per gm. dry gel.") No differences were observed in their behaviour. The dry gel was suspended in a large volume of 0·05 *M* sodium chloride, allowed to settle for about 15 min., and the supernatant decanted. This was repeated twice to remove fines, and the gel was then packed into the column. The gel was washed with distilled water until no chloride was detectable in the effluent. Some of the columns were used repeatedly and were washed with 0·1 *M* sodium chloride and distilled water before each run. The binding capacity of 'Sephadex *G*–50' at 25° was determined for several proteins as follows: a solution containing an amount of protein in excess of the capacity of the gel was passed through the column and the difference between the amount of protein applied and the amount eluted with water was measured. This value agreed with the quantity obtained by subsequent elution with 0·1 *M* sodium chloride. A representative experiment is illustrated in Fig. 1. The binding capacity of an 8·5 cm. × 1·2 cm. bed of 'Sephadex *G*–50' for lysozyme (egg white), ribonuclease (bovine pancreas), and bovine serum albumin was found to be 7·2, 2·8, and 2·4 mgm. respectively. Protein concentrations were determined by ultra-violet spectrophotometry. All the proteins tested were eluted quantitatively with 0·1 *M* sodium chloride. In an experiment with lysozyme, it was found that 10^{-2} *M* sodium chloride also eluted the protein quantitatively, whereas 10^{-3} *M* sodium chloride did not elute any of the adsorbed protein. Trypsin adsorbed to the gel was readily eluted with 10^{-3} *M* hydrochloric acid, but not with 10^{-4} *M* hydrochloric acid.

These findings suggested that use could be made of the strong binding of some proteins to 'Sephadex' to concentrate such proteins from dilute salt-free solutions. The following experiment illustrates this application and gives some indication of the binding strength involved. Four hundred ml. of a dilute ribonuclease solution (0·025 mgm./ml.) was passed through a column of 'Sephadex *G*–50', 11 cm. × 2·2 cm. It was found by determination of enzymatic activity[1] that the concentration of ribonuclease in the eluate was less than 0·1 per cent of that of the applied solution. The column was washed with an additional 300 ml. of water, and the enzyme was then eluted with 0·1 *M* sodium chloride. Fractions of 1·0 ml. were collected. All the enzyme was recovered, 93 per cent being present in 10 ml. Thus, a 40-fold concentration was achieved. The protein concentration in the peak fraction was 1·6 mgm./ml. The activity of the ribonuclease was not affected by adsorption to the gel. Not all proteins tested have been found to behave similarly to those mentioned here. Thus, neither yeast alcohol dehydrogenase nor pig pepsin was found to be adsorbed. The latter two enzymes were tested at 4° in order to minimize autolysis and denaturation.

The fact that the adsorbed proteins are eluted by dilute salt suggests that electrostatic interactions may play a part in the adsorption. Furthermore, the fact that dilute hydrochloric acid was an effective eluent and that pepsin, a highly acidic protein, was not adsorbed points to the possible presence of negatively charged groups in the gel. This view is also supported by the work of Gelotte[3], in which he found that the hydrochlorides of the basic amino-acids lysine, arginine and histidine are strongly adsorbed by 'Sephadex *G*–25' in water, whereas they are eluted by 0·05 *M* sodium chloride. Gelotte ascribed this behaviour to the presence of carboxyl groups in the gel. Other factors such as the aromatic group content[3,4] or the molecular weight of the protein may also influence the degree of binding. Although the adsorptive capacity of 'Sephadex *G*–50' is very small compared with that of ion-exchange celluloses[5], this property of the gel may acquire considerable significance when small quantities of protein are used.

CHEMISTRY

Estimation of Metal Content in Nickel Soaps by Polarography

HEAVY metal soaps with their many-sided technical and industrial applications present some unsolved problems to the chemists. One of these is the estimation of the amount of metal present in a particular soap. Until now the chemical analysis is generally used for this purpose. This method, besides being tedious, is apt to give less-accurate results, especially when the metal content is low. In the present communication some of the results of the polarography of nickel palmitate and myristate which have found a direct application in estimating the metal concentration are briefly described.

Boner[1] in 1937 showed the existence of complex ion formation between pyridine and metal soaps of Ni^{++}, Co^{++} and Cu^{++}. Polarography of the metal complexes of pyridine in the aqueous medium using potassium chloride as the supporting electrolyte was undertaken by Lingane and Kerlinger[2] in 1941. Since the soaps under investigation became hydrolysed with even traces of water, their polarography in non-aqueous media, using (1) lithium chloride in 1 : 1 benzene/methanol mixture[3]; (2) methyl hydrogen sulphate also in 1 : 1 benzene/methanol mixture[3]; (3) potassium chloride in glycol as supporting electrolyte was investigated. Measurements were carried out with a dropping mercury electrode with Lange's polarometer (model III, No. 46) in conjunction with the Multiflex galvanometer type *MGF* 2 at 25 ± 0·1° C. Inert atmosphere was maintained in the polarographic cell (*H*-type[4]) by passing purified nitrogen through it. The capillary constant $m^{2/3} t^{1/6}$ in the different supporting electrolytes were LiCl = 1·618; $MeHSO_4$ = 1·532; KCl = 1·610 mgm. sec.$^{-1/2}$. All the reagents used were either A.R. samples or product purified by standard methods in the laboratory. Nickel palmitate and myristate were prepared by precipitation method[5]; they were analysed for nickel content.

The polarograms in three different supporting electrolytes showed that the pyridine complex of both the soaps are reducible at the dropping mercury electrode and reversible waves (determined by the normal slope) with the $E_{1/2}$ values shown in Table 1 were obtained.

Table 1

Supporting electrolyte	$E_{1/2}$ (for Ni myristate) vs saturated calomel electrode	$E_{1/2}$ (for Ni palmitate) vs. saturated calomel electrode
0·166 *M* LiCl	– 0·74 volt	– 0 785 volt
0·166 *M* $MeHSO_4$	– 0·74 volt	– 0 700 volt
0·166 *M* KCl	– 0 802 volt	– 0 800 volt

Polarograms obtained with varying amounts of soap in pyridine gave waves having increasing diffusion current values with increasing concentration of the soap. Moreover, the value of diffusion current/concentration of soap was found to be constant for the different mixtures as can be seen from Table 2. From these results it was concluded that the polarographic method can be usefully utilized for the estimation of nickel in its metallic soaps.

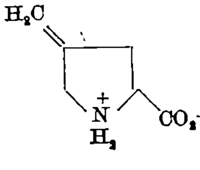
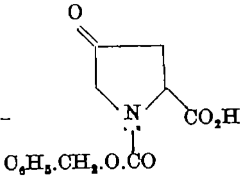
4-Methyleneproline : Synthetic Studies

RECENTLY, Gray and Fowden[1] have reported the isolation of a new amino-acid, 4-methylene proline (I), from seeds of loquat (*Eriobotrya japonica*). Structure (I) was firmly established by both chemical and spectroscopic evidence; but during the course of another investigation we have confirmed it by synthesis. This synthesis serves also to clarify some ambiguity concerning the optical configuration of the new amino-acid.



I



II

$(C_6H_5)_3P{=}CH_2$

III

Wittig reaction[2] between benzyloxycarbonyl-4-oxo-L-proline (II)[3] and methylenetriphenylphosphorane (III) yielded the oily benzyloxycarbonyl derivative of 4-methylene-L-proline. Its crystalline di*cyclo*hexylamine salt had m.p. 160–161° $[\alpha]^{19^\circ}_D - 5.5^\circ$ (*c*. 2 in chloroform) (found: C, 70·89; H, 8·63; N, 6·53. $C_{26}H_{38}O_4N_2$ requires C, 70·55; H, 8·65; N, 6·33 per cent). The natural amino-acid, generously provided by Dr. L. Fowden, was converted into its benzyloxycarbonyl derivative by treatment with benzylchloroformate at *p*H 10·3 (autotitrator) in aqueous acetone; the di*cyclo*hexylamine salt had m.p. 139° and no detectable optical rotation in chloroform solution (found: C, 70·21; H, 8·48; N, 6·63 per cent). In the solid state (nujol mulls) the two salts had distinctly different infra-red spectra, although the absorption bands corresponding to the principal functional groups were similar. In chloroform solution, however, the spectra were identical. Evidently the natural amino-acid is racemic, and this was confirmed by hydrogenation to a mixture of the *cis*- and *trans*-4-methylprolines (mainly the *cis* isomer[1]). We have shown previously that the optical rotations of the *cis* and *trans* isomers of 4-methyl-L-proline are both large and negative (−85° and −57° respectively)[4]. However, the hydrogenation product of the natural 4-methyleneproline had, within the limits of experimental error, no detectable rotation, and it can be concluded that less than 1 per cent of optically active material can be present.

4-Methyleneproline isolated from loquat seeds is therefore racemic, as suspected by Gray and Fowden[5]. This result is surprising, both in view of the rare occurrence of racemic amino-acids in Nature, and since the most plausible biogenetic precursor, 4-methylene-glutamic acid, has already been isolated in an optically active form[6], although from a different plant source.

Benzyloxycarbonyl-4-methylene-L-proline is a possible precursor for stereospecific synthesis of 4-hydroxymethylproline, the configuration of which is at present a matter of discussion[7].

Use of Amines in Inorganic Hydrolysis

FOLLOWING the work of Smith and Page[1], amines have been widely used for the extraction of acids from aqueous solutions. We have applied this process to the hydrolysis of inorganic salts in aqueous solution without the introduction of any reagents into the aqueous phase. An amine which is immiscible with the aqueous phase is used to extract the acid formed on the hydrolysis of the salt and under suitable conditions insoluble complexes can be precipitated. Thus complexes of UO_2^{++}, Th^{4+}, Fe^{3+} and $RuNO^{3+}$ have been precipitated by us, and although the anion has usually been nitrate we have also carried out precipitations from sulphate media. Other anions could also be used since amines extract many acids efficiently (see, for example, Moore[2]).

The hydrolysis of uranyl nitrate can be made to proceed until a uranium complex is precipitated; for example, in a typical experiment when a 0·89 *M* solution of uranyl nitrate in water was stirred with 0·5 *M* trinonylamine (tri-3 : 5 : 5-trimethylhexylamine) in xylene for 5 min. at room temperature a yellow precipitate was formed. After washing with water and drying at 60° C. the composition of the solid corresponded to $UO_3.2H_2O$ (found: U = 73·2 per cent, H_2O = 12·7 per cent; calculated for $UO_3.2H_2O$, U = 73·8 per cent, H_2O = 11·2 per cent). The product was contaminated by xylene as shown by a carbon content of 0·76 per cent; but nitrogen could not be detected showing that no amine was present. The identity of the product was confirmed by X-ray examination and by differential thermal analysis (which indicated that it was the α-form of $UO_3.2H_2O$).

The precipitated complexes are probably of the type $UO_3.2H_2O.x$ amine and their stability varies with the type of amine, for example, with a tertiary amine, such as trinonylamine, the amine can be removed by thorough washing followed by drying at 60° C., but this is not the case if a primary amine such as 'Primene *JM-T*' (a proprietary mixture of alkyl primary amines with carbon chains ranging from C_{16} to C_{22}) is used. Dioctylamine (DOA, a mixture of the di-iso-octylamine isomers) gives a uranium–amine complex corresponding approximately to $UO_3.2H_2O.$ (DOA) and in stability to washing this is intermediate between the complexes formed by the primary and the tertiary amines examined. The efficiency of precipitation depends on the basicity of the amine and on the relative amounts of amine and acid. We have found precipitation efficiencies of about 99 per cent for the precipitation of uranium with 'Primene *JM-T*' dissolved in kerosene or with DOA dissolved in xylene using amine : uranyl nitrate mole ratios of approximately 3 : 1.

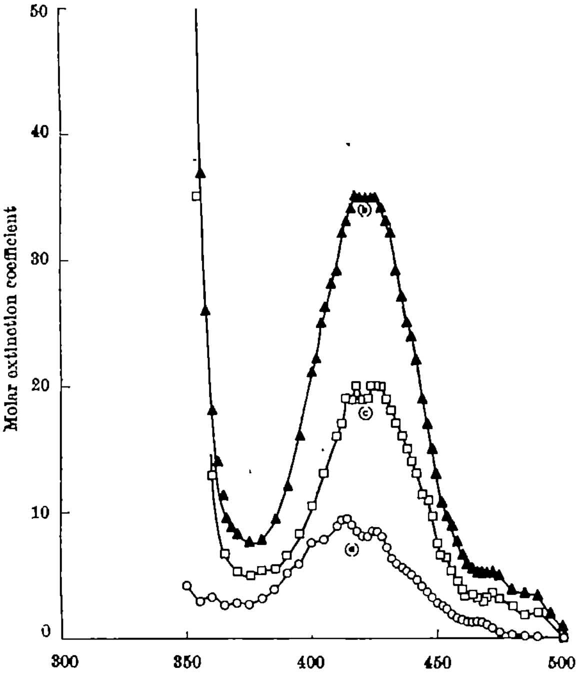

Fig. 1. Absorption spectra: *a*, aqueous uranyl nitrate; *b*, the same solution after extracting 52·9 per cent of the nitrate (no uranium precipitated); *c*, the supernatant liquor after extracting 93 per cent of the nitrate (82 per cent of the uranium precipitated)

The method described here can also be used for the examination of hydrolytic reactions taking place in aqueous solutions, again without introducing reagents into the aqueous phase (the solubility of trinonylamine in water is less than 5 parts per million). This is illustrated in Fig. 1, which gives the absorption spectra of (*a*) aqueous uranyl nitrate solution, (*b*) the same solution after 52·9 per cent of the nitrate has been extracted into trinonylamine (but no uranium has been precipitated) and (*c*) the supernatant liquor after 93 per cent of the nitrate has been extracted into trinonylamine from a 0·24 *M* solution of uranyl nitrate in water, and 82 per cent of the uranium has been precipitated. The spectra of the hydrolytic species resemble those found in the titration of uranyl perchlorate with sodium hydroxide[3], and the extent of hydrolysis may be controlled by choice of amine, concentration of amine and by variation in the relative phase volumes of amine and aqueous phases.

We thank Dr. E. Wait for the X-ray examination and Dr. R. M. Dell for the differential thermal analysis. We are grateful to Imperial Chemical Industries, Ltd., for supplies of trinonylamine and dioctylamine and to C. Lennig and Co., Ltd., for 'Primene *JM-T*'.

BIOCHEMISTRY

Xanthophyll Pigmentation in Sheep Fat

CASTLE[1] concluded from the observations of Zophoniasson that the yellow fat appearing in some Icelandic sheep is due to a simple recessive character in inheritance. I have recently examined the chemical nature of the yellow pigments in the adipose tissue of some Irish sheep. The yellow fat was rendered from the adipose tissue by heating in an oven at 60° C. One hundred and fifty grams were saponified by heating with 300 ml. of 20 per cent alcoholic potassium hydroxide. After dilution with 900 ml. of water the pigments were extracted using 1,200 ml. of diethyl ether. Complete extraction was accomplished by using 600-ml. portions of ether in two or three subsequent extractions. After washing with water and drying over anhydrous sodium sulphate the ether was distilled off under nitrogen on a water bath. The residue of crude pigments and cholesterol was dissolved in 5 ml. of hexane and chilled. After filtration, from unsaponified material deposited during chilling, the pigment extract was made up to 50 ml. using hexane.

The yellow colour of a petroleum ether 40°–60° C. solution of the pigments was completely extracted by 90 per cent v/v aqueous methanol, thus proving the presence of xanthophylls and the absence of carotene. When the hexane solution was chromatographed on a magnesium oxide column and developed with a mixture containing 82·5 per cent hexane, 15 per cent acetone and 2·5 per cent ethanol, the pigment mixture was resolved into three yellow bands designated *A*, *B* and *C* in order of increasing adsorption. Fractions *A* and *B* were eluted by the developer and collected separately. Fraction *C* was eluted by 8 per cent ethanol in hexane. After washing with water and drying over anhydrous sodium sulphate each of the three fractions was re-chromatographed on a column of de-activated aluminium oxide, and solutions of ethanol in hexane (2 and 4 per cent) were used as developer. Minor bands obtained by this treatment were separated from the main fractions *A*, *B* and *C*. These three fractions after elution from the de-activated aluminium oxide were incapable of further resolution when washed, dried and re-chromatographed on a basic zinc carbonate column

Table 1. SPECTROPHOTOMETRIC CONSTANTS OF LUTEIN, LUTEIN-5 : 6-EPOXIDE, FLAVOXANTHIN AND OF FRACTIONS *A*, *B* AND *C*. MAXIMA ARE EXPRESSED IN MILLIMICRONS

	Hexane	Carbon disulphide	Chloroform	Benzene
Lutein	420,447,477	—	428,456,487	—
Fraction *A*	419,445,475	—	426,450,480	—
Lutein-5 : 6-epoxide	442,471	472,502	—	453,482
Fraction *B*	443,472	473,501	—	453,482
Flavoxanthin	421,450	—	430,459	432,456 (ref. 3)
Fraction *C*	421,448	—	430,455	432,455

and developed with 20 per cent ether in benzene. Fraction *A* and lutein prepared from grass were found to be chromatographically homogeneous.

Table 1 shows the position of the absorption spectra maxima of the three purified fractions *A*, *B* and *C* in various solvents and also gives the spectrophotometric constants of lutein, lutein-5 : 6-epoxide and flavoxanthin as given by Goodwin[2]. It is concluded from the chromatographic homogeneity of fraction *A* and lutein, the positions of the pigments on the magnesium oxide column[1], the spectrophotometric constants of the fractions in the various solvents and the shape of the absorption curves, three of which are shown in Figs. 1, 2 and 3, that fraction *A* is lutein, fraction *B* is very probably lutein-5 : 6-epoxide and fraction *C* is most likely flavoxanthin. All these three xanthophylls are present in green tissues[3]. The lutein-5 : 6-epoxide appeared to be present in greatest concentration, though it is possible that some lutein was lost during the saponification.

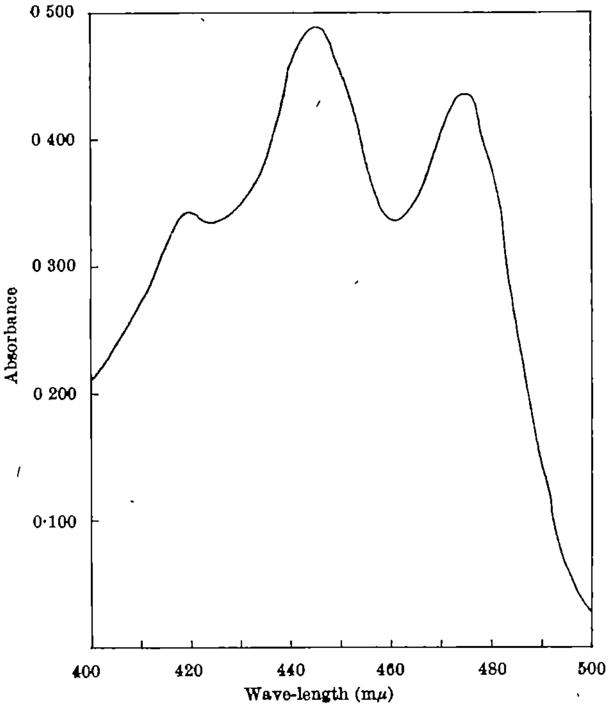

Fig. 1. Visible absorption spectrum in hexane of lutein extracted from yellow sheep fat

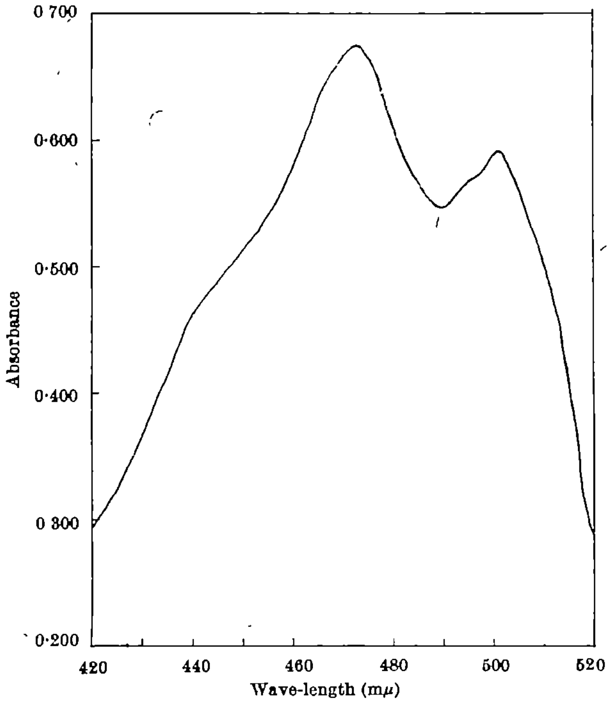

Fig. 2. Visible absorption spectrum in carbon disulphide of lutein-5 : 6-epoxide extracted from yellow sheep fat

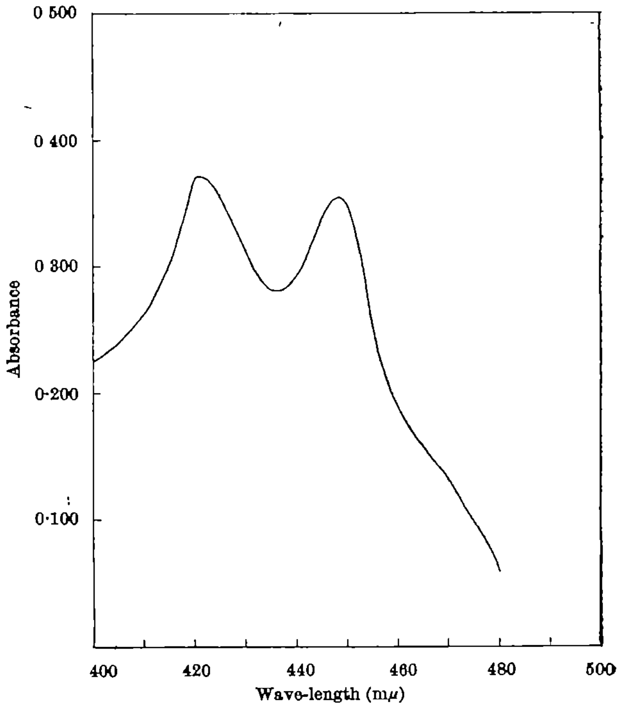

Fig. 3. Visible absorption spectrum in hexane of flavoxanthin extracted from yellow sheep fat

It would seem that the yellow fatted sheep has inherited the inability to oxidize the xanthophylls. The primitive sheep may have been deficient in a 'xanthophyll oxidase' system and the yellow-fatted sheep of to-day may be atavistic in possessing yellow fat. The only other animal which has been reported to store xanthophylls exclusively in its adipose tissue is the yellow-fatted rabbit[4]. A yellow-fatted sheep may be detected before slaughter by the following rapid test. The proteins of a sample of the sheep's blood serum are precipitated by ethyl alcohol. Extraction with diethyl ether brings the xanthophylls into the ether layer. A yellow colour in the ether layer indicates a yellow-fatted sheep. A full account of this work will be published elsewhere[5].

A Mammalian Peptidase specific for the Hydrolysis of *N*-Terminal α-L-Glutamyl and Aspartyl Residues

THE histochemical visualization of a calcium activated *N*(α-L-glutamyl)β-naphthylamide-cleaving activity has been described in an earlier publication[1]. Hydrolysis of *N*(α-L-aspartyl)β-naphthylamide has now been observed histochemically in sites identical to those described for *N*(α-L-glutamyl)β-naphthylamide (for example, guinea pig pancreatic duct epithelium and islets of Langerhans and human and rat glomeruli) in the presence of the optimal concentration of the activating ion, calcium. The above tissue section localizations of the enzymatically catalysed hydrolysis of the α-L-glutamyl and α-L-aspartyl substrates are distinct from those seen with other β-naphthylamide substrates in the presence of calcium ions.

An enzyme having the characteristics noted here, aminopeptidase *A*, has been partially purified from rat kidney by the following method. The microsomal fraction derived from sucrose or potassium chloride homogenates of rat kidneys was resuspended in 0·001 *M tris*(hydroxyamino)methane buffer at *p*H 7·5. The particulate suspension was subjected to digestion by a mixture of trypsin and chymotrypsin. Centrifugation of the digest at 100,000*g* gave a particulate fraction containing essentially all the aminopeptidase *A* activity and was devoid of significant activity toward glycyl, L-leucyl, α-L-glutaminyl, DL-alanyl, or DL-phenylalanyl-β-naphthylamide.

Parallel calcium ion activation of *N*(α-L-glutamyl)-β-naphthylamide and *N*(α-L-aspartyl)β-naphthylamide is apparent from the results given in Table 1.

Table 1. LIBERATION OF β-NAPHTHYLAMINE (mμMOLES/MIN./MGM ENZYME)

	Additions to incubation solution*	Substrate	
		α-L-Glutamyl-β-naphthylamide	α-L-Aspartyl-β-naphthylamide
1	None	27	3·3
2	0·001 *M* $CaCl_2$	55	9·2
3	0·01 *M* $CaCl_2$	65	11
4	0·02 *M* $CaCl_2$	62	11
5	0·01 *M* Ethylenediamine tetraacetate	3·3	0·3
6	0·01 *M* $CaCl_2$ and 0·002 *M* α-L-Glutamyl-L-phenylalanine	20	2·2

* Incubation solution. Enzyme, 0·06 mgm. dry weight, substrate, 0·41 mgm. α-L-glutamyl-β-naphthylamide or 0·39 mgm. α-L-aspartyl-β-naphthylamide; fast garnet GBC, 0·5 mgm.; in 3 ml. 0·1 *M tris*-(hydroxyamino)methane-maleate buffer, *p*H 7·0, 37° C. The reaction was stopped after 10 min. by the addition of 1 ml. 10 per cent 'Tween 20' in 1 *M* acetate buffer, *p*H 4·2. After 30 min. absorbance at 525 mμ was determined.

Disodium ethylenediamine tetraacetate and α-L-glutamyl-L-phenylalanine produced an inhibitory effect on the hydrolysis of the aspartyl substrate equivalent to that produced on the glutamyl substrate. The inhibition by α-L-glutamyl-L-phenylalanine was found to be of a competitive nature. No effect on hydrolysis was afforded by L-leucinamide, L-leucylglycine or glycyl-glycine (0·002 *M*). The dipeptides α-L-glutamyl-L-phenylalanine and α-L-aspartyl-L-arginine were defined as substrates for aminopeptidase *A* by chromatographic identification of constituent amino-acids of each dipeptide following incubation with the enzyme. No hydrolysis of *N*(α-D-glutamyl)β-naphthylamide, *N*(N^{α}-benzoyl-α-L-glutamyl)β-naphthylamide or *N*-carbobenzoxy-α-L-glutamyl-L-phenylalanine was observed in the presence of high concentrations of aminopeptidase *A*.

Strong evidence that the hydrolysis of both the *N*(α-L-aspartyl)- and *N*(α-L-glutamyl)β-naphthylamide substrates is catalysed by the same enzyme is afforded by the identical effects of activator and inhibitors on the hydrolysis of these substrates and the identical histochemical localization obtained with both. Moreover, the maximum velocity determined by the method of Lineweaver and Burk using an equimolar mixture of naphthylamide substrates was found to lie between the maximum velocities of the individual substrates, again attesting to the fact that only one enzyme is involved in the hydrolytic reactions.

The absence of hydrolysis of *N*(α-D-glutamyl)β-naphthylamide and *N*(N^{α}-benzoyl-α-L-glutamyl)β-naphthylamide in both the histochemical and biochemical systems and of *N*-carbobenzoxy-α-L-glutamyl-L-phenylalanine in the biochemical system indicates that aminopeptidase *A* is stereospecific and exhibits primarily exopeptidase activity.

The biochemical data confirm the existence of the histochemically defined peptidase having a relative specificity for *N*-terminal L-dicarboxylic amino-acids. For convenience and clarity of nomenclature this enzyme is referred to as aminopeptidase *A* (acid α-amino peptidase) to distinguish it from classic leucine amino peptidase[2] and enzymes hydrolysing acidic omega amino[3] and non-acidic α-amino-acid β-naphthylamides[4].

Pig kidney and duodenum are good sources of aminopeptidase *A* and further investigations to obtain a more purified preparation from these sources are in progress. A report of these studies as well as a detailed account of the kinetics of aminopeptidase *A* activity, its application as an end group reagent, the steric and chemical limits of specificity of the enzyme toward synthetic substrates and procedures for the syntheses of these substrates will be the subject of future communications.

Adrenal Glucose-6-Phosphatase: Alterations in Intracellular Distribution induced by Treatment with Adrenocorticotrophic Hormone

HAYNES *et al.*[1] have proposed a mechanism of the action of adrenocorticotrophic hormone (ACTH) on the adrenal gland in which glucose-6-phosphate (G-6-P) plays a most important part. The increased rate of production of G-6-P, arising from the activation of phosphorylase by ACTH to produce increased quantities of glucose-1-phosphate and the subsequent conversion of the glucose-1-phosphate to G-6-P by phosphoglucomutase, results in an increased metabolism of G-6-P by oxidation to 6-phosphogluconic acid. This oxidation produces reduced triphosphopyridin nucleotide (TPNH) and the TPNH serves as a source of energy for various steps in the production of steroids[2]. However, G-6-P may also be metabolized by dephosphorylation, affected by the enzyme glucose-6-phosphatase (G-6-Ptase).

Since we have been examining the effect of treatment with ACTH on certain adrenal enzymes[3], we felt that an investigation of the effects of ACTH on G-6-Ptase might provide further insight into the metabolism of G-6-P. In this communication results are presented indicating that ACTH treatment caused a change in activity and intracellular distribution of G-6-Ptase.

For preparation of adrenal particulate and soluble cell fractions, approximately 500–700 mgm. of adrenals were collected (100–125 mice) and pooled prior to homogenization. Details of the procedure were given earlier[3]. In order to study the effect of ACTH on enzyme activity in cell fractions, another preparation was made from animals killed 30–45 min. following the subcutaneous injection of 500 milliunits of ACTH. Prior to enzyme assay, each cell fraction was resuspended by briefly homogenizing in a sufficient volume of 0·25 molar sucrose. G-6-Ptase was assayed by Swanson's method[4]. Nitrogen determinations were performed using a modification of the Pregl micro-Kjeldahl method[5]. Enzyme activity (mean of quadruplicate determinations) was expressed in terms of nitrogen.

Table 1 illustrates the intracellular distribution of G-6-Ptase in normal adrenal glands. The results indicate that this enzyme appears to be localized in the microsomal fraction, a result similar to that reported for liver G-6-Ptase[6]. However, following the *in vivo* treatment with ACTH, several differences were observed as recorded in Table 1. The G-6-Ptase activity was found also in the nuclear and mitochondrial fractions, and in small amounts in the soluble cytoplasm as well (less than 2 per cent of the total activity). The most striking difference was the microsomal G-6-Ptase activity, which decreased to less than 50 per cent of the value found in normal glands. Total activity was decreased by approximately 20 per cent.

Table 1. LOCALIZATION OF GLUCOSE-6-PHOSPHATASE ACTIVITY IN ADRENAL CELL FRACTIONS BEFORE AND AFTER ACTH TREATMENT

Cell fraction	Nitrogen (mgm./gm. tissue)	Specific activity*	Total activity†	Total activity (per cent)

* Specific activity expressed as μgm. inorganic phosphate released/μgm. nitrogen.

† Total activity expressed as mgm inorganic phosphate released/gm. protein

If one assumes that a change in G-6-Ptase activity is a reflexion of some alteration in the metabolism of G-6-P, then the data presented here suggest that treatment with ACTH causes a rapid change in the metabolism of this compound. However, the exact relationship of these changes of enzyme to the production of adrenocortical steroids is not known. One possible explanation is that the decrease in G-6-Ptase activity might shunt the metabolism of G-6-P partly towards oxidation, since it has been shown that an increase in G-6-Ptase activity favours the formation of the oxidized form of TPN[7]. If the metabolism of G-6-P via oxidation (hexose monophosphate shunt) in the microsomes is enhanced, then it would follow that the production of TPNH would be increased. There are reports indicating that, following the administration of ACTH. adrenal TPNH rises[1]. On the other hand, the appearance of extra-microsomal G-6-Ptase activity following ACTH treatment suggests an increased G-6-P metabolism by dephosphorylation, favouring the formation of TPN. Further work is necessary to elucidate these intracellular relationships.

Effect of Dietary Linolenate on the Proportion of Linoleate and Arachidonite in Liver Fat

PRELIMINARY experiments have suggested that feeding of linseed oil fatty acids depressed the proportion of arachidonic acid in liver and cerebella of chickens[1]. The following experiment was conducted to determine the validity of the original observation.

Day-old Nichols 108 cockerels were fed a purified low-fat diet for seven days. They were then divided into groups of 8 birds each and fed diets containing either ethyl linoleate or linseed fatty acids added at the expense of glucose. The chickens were fed the experimental diets until they were 35 days old. They were then fasted overnight, killed, and the liver analysed for fatty acids using gas chromatography. The results are given in Table 1.

Table 1. EFFECT OF DIETARY FAT ON THE FATTY ACID COMPOSITION OF LIVERS FROM 35-DAY-OLD CHICKENS

* 75 per cent ethyl linoleate, Nutritional Biochemicals, Cleveland, Ohio. This diet contains 1 5 per cent 18:2.

† Diet *C*-21 (casein, amino-acid, glucose, vitamins and minerals[2]) modified by deletion of methyl myristate and increasing arginine to 0 9 per cent

‡ Per cent by weight of total fatty acids in liver. Average of 3 replicates ±*S.D.*

§ Veg. Acid 520, Archer Daniels Midland, Minneapolis, Minn. This contains 47 per cent 18 3 and 17 per cent 18:2. The diet contains 1 7 per cent 18 2.

The linoleic acid content of the diets containing 10 per cent linseed fatty acids or 2 per cent ethyl linoleate is about the same (1·7 per cent and 1·5 per cent respectively). Nevertheless, the percentage of linoleic in the liver of chickens fed the linseed fatty acids was approximately twice the level observed in the livers of the birds fed 2 per cent linoleate. The arachidonic acid was significantly ($P < 0\cdot05$ by the t test) lower in the birds consuming linseed oil fatty acids. Since arachidonic acid is synthesized from linoleic acid[3] our observations suggest that the linolenic acid in the linseed fatty acids is inhibiting the conversion of linoleic acid to arachidonic acid.

This hypothesis, however, should be confirmed by the feeding of pure linolenic acid and preferably by the use of carbon-14 labelled linoleic acid.

Elastin a Sialoprotein

THE aorta consists of elastin, collagen and a number of other proteins; it also contains about 2 per cent of carbohydrate[1]. Elastin is usually isolated from aorta or ligamentum nuchæ by treatment with acids and alkalis at elevated temperatures; however, a small amount of ill-defined carbohydrate appears to be held strongly and cannot be easily removed[2]. It is possible that this sugar moiety is an integral part of elastin.

The object of the work reported here was to isolate a fragment containing the elastin-sugar linkage using very mild conditions, and to investigate its nature.

A bovine aorta was cleaned, minced in the cold and treated in turn with pepsin at *p*H 2·5, trypsin at *p*H 7·5, and collagenase at *p*H 7·0. The residue was washed well after each treatment, which lasted 30–40 hr. at 37°. The tryptin digest contained most of the acid mucopolysaccharide, as judged by the content of hexosamine and hexuronic acid. The final residue, which accounted for about 50 per cent of dry aorta, was then treated exhaustively with pure elastase at *p*H 8·5 (preparation *E*,I, Hall and Czerkawski[3]), which resulted in more than 90 per cent solubilization. Dialysis of the solubilized material gave approximately equal amounts of diffusate and retentate.

Although both fractions of elastolysate had similar amino-acid composition, the diffusate was devoid of carbohydrate. The retentate, which is practically resistant to further action by elastase, contains about 0·5 per cent of a substance giving the usual reactions for sugars. It contains no glucosamine or galactosamine, but approximately equal amounts of sialic and hexuronic acids. The presence of the former was first indicated by considerable humin formation during hydrolysis in strong mineral acid, and finally confirmed by the positive Bial and direct Ehrlich reactions The actual amount of sialic acid was estimated after a mild acid hydrolysis (1 hr. at 80° in 0·1 *N* sulphuric acid) by the thiobarbiturate and alkali-Ehrlich methods of Aminhoff[4]. Such hydrolysis did no damage to the protein and certainly did not remove the hexuronic acid (Table 1, col. 3), and although it made the sialic acid reactive to thiobarbiturate, probably due to hydrolysis of the glycosidic bond on C2, it did not produce a complete cleavage, because the sugar could not be separated from the residual protein by dialysis. When the products of mild hydrolysis were subjected to dialysis, no sialic acid could be detected in either the diffusate or retentate. The reactivity of sialic acid with the thiobarbiturate reagent could be restored when the retentate was again hydrolysed for 1 hr. at 80° in 0·1 *N* acid. This can be explained by supposing that the mild acid hydrolysis breaks only one of two linkages joining sialic acid to elastin, and that subsequent dialysis results in the reformation of this bond (Table 1, col. 2).

Table 1 ANALYSIS OF SUGAR COMPONENTS AND REACTIVITY TO ELASTASE OF THE RETENTATE FRACTION

Treatment	Apparent content of sialic acid (per cent)	Content of hexuronic acid (per cent)	Elastolytic activity (arbitrary units)
None	0·02	0·23	7·0
Mild acid hydrolysis	0·29	0·23	19·8
Dialysis (retentate)	0·02	0·19	12·0
Another hydrolysis (retentate)	0·23	—	—

The sialic acid was determined by Aminoff's method (ref. 4), and the hexuronic acid was determined directly by the method of Bitter and Ewins (ref. 5). The elastolytic activity was determined by the trichloroacetic acid precipitation method as described by Hall and Czerkawski (ref. 6).

The ability to react with thiobarbiturate is paralleled by the susceptibility of the retentate fraction to further attack by elastase. The mild acid hydrolysis makes the protein susceptible to further proteolytic attack, but this newly acquired susceptibility is greatly reduced after dialysis (Table 1, col. 4).

It is too early to venture any firm conclusions at this stage; but there is every indication that sialic acid is doubly linked to elastin and so is a cross-linking agent, probably in association with the hexuronic acid. It is possible, that it occupies a strategic position, because, although present in such small amount (about 1 mole/10⁵ gm.), it plays an important part in the reaction with elastase. This last fact also makes it unlikely that the sialic and hexuronic acids are part of a large polysaccharide polymer; on the contrary, they are probably uniformly distributed throughout the solid elastin.

m-Hydroxyphenylpropionic Acid, a Major Urinary Metabolite of (+)-Catechin in the Rat

ALTHOUGH substances of the flavonoid type are present in many foodstuffs of plant origin the metabolic fate of these compounds in mammalian metabolism was until recently largely unknown. The compounds on which recent investigation has been centred, however, are of either the flavonol[1-5], the flavanone or the flavone type[6]. It appeared to be of interest. therefore, to study the fate of a compound of the related catechin type, in which the keto group at C4 is absent.

A group of male albino rats were placed on a standardized, low flavonoid diet based on milk powder and white flour with salt and vitamin supplements. After a period of two weeks, the rats were divided into control and experimental groups, the control group being maintained on the foregoing diet while each rat of the experimental group received 50 mgm. (+)-catechin in admixture with the same food powder. The urine was collected over a period of 3 days following the administration of catechin and ethereal extracts prepared for chromatography by the method of Booth *et al.*[1]. The amount of ethereal extract applied to each chromatogram was equivalent to 2 ml. of fresh urine.

Examination of the extracts in the two-dimensional system, chloroform/acetic acid/water, 2 : 1 : 1 (lower phase) and 20 per cent potassium chloride[1], revealed the presence of a compound (compound *X*, Table 1) in the urine of the catechin-fed rats which was shown to be chromatographically identical with an authentic specimen of *m*-hydroxyphenylpropionic acid. Although the compound was present in relatively large amounts in the urine of catechin-fed rats, it was completely absent from the control chromatograms. The identity of the compound was afterwards confirmed (Table 1) using a second two-dimensional system, employing isopropyl alcohol/aqueous ammonia/water, 8 : 1 : 1 (ref. 7), and benzene/acetic acid/water, 60 : 70 : 30 (ref. 8).

Table 1. CHROMATOGRAPHIC BEHAVIOUR OF *m*-HYDROXYPHENYLPROPIONIC ACID AND COMPOUND *X*

	m-OH-phenyl-propionic acid R_F	Compound *X* R_F
Chloroform, acetic acid, water	0·75	0·75
20 per cent KCl	0·71	0·71
Isopropyl alcohol aq. NH_3, water	0·64	0·64
Benzene, acetic acid, water	0·66	0·66
Diazotized *p*-nitraniline	Red-purple	Red-purple
Diazotized sulphanilic acid	Orange-yellow	Orange-yellow

Both the catechin metabolite described and *m*-hydroxyphenylpropionic acid gave identical colour reactions with the spray reagents diazotized *p*-nitraniline and diazotized sulphanilic acid (purple-red and orange-yellow respectively).

The formation of a phenyl-propionyl derivative from (+)-catechin indicates that ring fission occurs between C4 and the adjacent C atom of ring *A* without any break between C3 and C4. Since ring fission of this type is given by flavan-4-ones and flavones[6] but not by flavonols, which yield only phenylacetyl derivatives[1], it is thought likely that dehydroxylation at C3 accompanied by oxidation of the C4 atom to a carbonyl group occurs before ring fission. Conversion of (+)-catechin to a flavanone structure could be effected in two steps: (1) Oxidation of (+)-catechin to the corresponding flavan-3 : 4-diol. (2) Removal of the elements of water from the 3 : 4-diol grouping to give the corresponding flavan-4-one.

The dehydroxylation observed with respect to the C4′ of the benzenoid ring of the catechin molecule appears to parallel that already reported to occur during metabolism of both 3′,4′-dihydroxy flavonols and 3′ : 4′-dihydroxy-flavanones in the rat[1,6]. *p*-Dehydroxylation of a 3 : 4-dihydroxyphenylalkyl acid also was reported recently by Scheline, Williams and Witt[9].

Of three types of urine sample collected (namely, 0–24 hr., 24–48 hr., 48–72 hr. after administration of catechin), the maximal level of *m*-hydroxyphenylpropionic acid was usually found in the 24–48 hr. sample; the acid not infrequently being wholly absent from the first sample (0–24 hr.) This may be due either to catechin being slowly absorbed from the gut or to formation of *m*-hydroxyphenylpropionic acid from catechin being dependent on the action of the intestinal microflora. Experiments are at present being carried out to clarify this point.

The demonstration of the formation of *m*-hydroxyphenylpropionic acid from (+)-catechin in the rat suggests a possible origin for the *m*-hydroxyphenylpropionic acid, detected by Armstrong *et al.*[7], in human urine, since catechins and their derivatives are known to be present in tea[10] and cocoa[11,12].

Alkali Metal Requirements in Oxidative Phosphorylation

THE selective binding of potassium ions by mitochondria and their digitonin sub-fragments, coupled with the finding that active electron transport is required for maximal binding[1], indicates the importance of determining the effect of the alkali metal ions on oxidative phosphorylation processes in these organelles.

A loss of K^+ occurs from uncoupled mitochondria using a variety of metabolic inhibitors[1–3], and this effect can be produced even at 0° (refs. 4 and 5). Tapley[6] has suggested that the loss of K^+ from mitochondria may be the primary defect, and in fact be responsible for such uncoupling action.

Boyer, Lardy and Phillips[7] have shown that K^+ were required by liver minces to produce esterification of phosphate during the oxidation of pyruvate. Pressman and Lardy[8] have claimed a stimulation of mitochondrial respiration by K^+, with no effect on phosphorylation, although phosphorylation was not measured directly. Few direct studies have been made since, and most investigations have replaced one metal with another, changing sucrose to maintain tonicity. As sodium may substitute for potassium it was felt that the replacement of one ion by the other, either in part or in full, did not produce conclusive evidence. In addition sucrose alone is inhibitory to mitochondrial function[9].

In this work a medium which was both free of potassium and with a very low concentration of sodium was used. The source of inorganic phosphorus was obtained by neutralizing dilute phosphoric acid to *p*H 7·0 with *tris*hydroxymethylmethane buffer (*tris*). The substrates (α-oxo-glutaric and succinic acids) were used as the free acids also neutralized to pH 7·0 with *tris*. Adenosine triphosphate (Sigma) was included either as the disodium salt for low Na^+ concentrations or prepared as the free acid from a 'Dowex 50 × H' column and then neutralized to pH 7·0 with *tris* to give an Na^+ free medium. Human serum albumin, prepared by exhaustive dialysis of albumin concentrate (Commonwealth Serum Laboratories) against electrolyte free water, was used to provide tonicity.

Rat liver mitochondria were prepared essentially by the method of Schneider[10] and were examined in a conventional Warburg apparatus at 30° C. The mitochondria equivalent to 0·75 gm. of fresh liver tissue were added last, in 0·5 ml. of ice cold 0·25 M sucrose, to each vessel. The final concentration of reactants in each Warburg vessel was as follows: magnesium chloride 5 mM; adenosine triphosphate 2 mM; substrate 10 mM; glucose 16 mM; albumin 0·75 per cent. 30 units of Sigma (III) hexokinase in 1 per cent glucose When required, sodium and potassium ions were provided by the addition of the chloride salts.

The concentration of either Na^+ or K^+ in the alkali ion free medium was shown by flame spectrophotometry to be less than 10^{-4} M.

In this medium, liver mitochondria carried active oxidation and phosphorylation in the presence of both α-oxo-glutarate and succinate. The phosphorus/oxygen ratios obtained under these conditions were 1·9 and 1·0 respectively. The addition of 5 mM Na^+ had little effect but a marked inhibition of both oxidation and phosphorylation occurred when the concentration of Na^+ was increased to 75 mM. An increase in metabolic activity was not produced by the addition of 75 mM K^+ to the medium. A small but constant inhibition of both oxidation and phosphorylation occurred under these conditions. These results are shown in Table 1.

Table 1. EFFECT OF Na^+ AND K^+ ON THE EFFICIENCY OF MITOCHONDRIAL OXIDATIVE PHOSPHORYLATION

Substrate	Alkali ion	concentration (mM)	No of exp.	Mean Pi* uptake	Mean oxygen* utilization	P/O
α-oxo-glutarate	Na^+	0	4	20·9 (19·2–21·9)	10·7 (10·4–11·2)	1·9
	K^+	0				
	Na^+	5	4	19·7 (18·4–22·0)	10·4 (10·0–11·6)	1·9
	K^+	0

Table 2. EFFECT OF SUSPENDING MITOCHONDRIA FOR 10 MIN AT 0° C. IN A SUCROSE MEDIUM CONTAINING 5 mM SODIUM SALICYLATE, ON OXIDATIVE PHOSPHORYLATION

Substrate	Alkali ion	concentration (mM)	No. of exp.	Mean Pi* uptake	Mean oxygen* utilization	P/O
α-oxo-glutarate	Na^+	5	2	24·6 (24·5–24·8)	14·5 (14·5–14·6)	1·7
	K^+	0				
	Na^+	5	2	12·9 (11·5–14·3)	9·0 (8·0–10·0)	1·4
	K^+	75				
Succinate	Na^+	5	2	30·2 (29·9–30·6)	25·3 (24·6–26·0)	1·2
	K^+	0				
	Na^+	5	2	1·2 (0·9–1·54)	15·8 (15·8–15·8)	0·1
	K^+	75				

* μatoms/12·5 mgm. protein/15 min.

In some experiments the measurement of oxidative phosphorylation was made after suspending the mitochondria for 10 min. at 0° C. in a 0·44 M sucrose medium containing 5 mM sodium salicylate prior to final separation. This was done because previous work in these laboratories had shown that this procedure results in a marked increase in the loss of bound K^+ from mitochondria (> 60 per cent) under these conditions, and that the loss of K^+ is not compensated for by replacement with Na^+ (ref. 5).

Results of these experiments are given in Table 2, and demonstrate that even a considerable loss of bound mitochondrial K^+ prior to incubation had little effect on the efficiency of oxidative phosphorylation when the mitochondria were examined in a K^+ free medium, although an increase in respiratory activity was apparent in these mitochondria. The addition of 75 mM K^+ to the medium under these conditions produced considerable inhibition of respiration with either substrate. However, phosphorylation was only slightly reduced when α-oxo-glutarate was the substrate, but was markedly decreased when succinate was the substrate.

These results suggest that K^+ binding and K^+ exchange are not required for efficient mitochondrial respiration and phosphorylation, and that the loss of bound K^+ from mitochondria *per se* will not uncouple oxidative phosphorylation.

PHYSIOLOGY

Effect of DL-Methionine Sulphoximine on Incorporation of ^{35}S-Methionine into Proteins of Brain Cortex Slices

IT has been shown by a number of authors that the administration of methionine sulphoximine (MSI) to experimental animals produces convulsions similar to epileptic seizures. Many metabolic disturbances occurred in the tissue of the brain under these conditions[1,2], one of these being the inhibition of ^{35}S-methionine incorporation into brain proteins *in vivo*[3-5]. However, the exact mode of action of MSI remains, so far, unknown.

To obtain more information about the connexion between MSI and protein metabolism of the brain, I have examined the effect of this substance on incorporation of ^{35}S-methionine into proteins of brain cortex slices *in vitro*.

The brain was rapidly excised following decapitation of the animal and sliced on an ice-cold block. The slices were incubated in a Warburg apparatus in Krebs–Ringer phosphate-saline, pH 7·4, containing 0·01 M glucose and 6 μc. ^{35}S-methionine (per vessel) of 279 mc./gm. specific activity. DL-Methionine

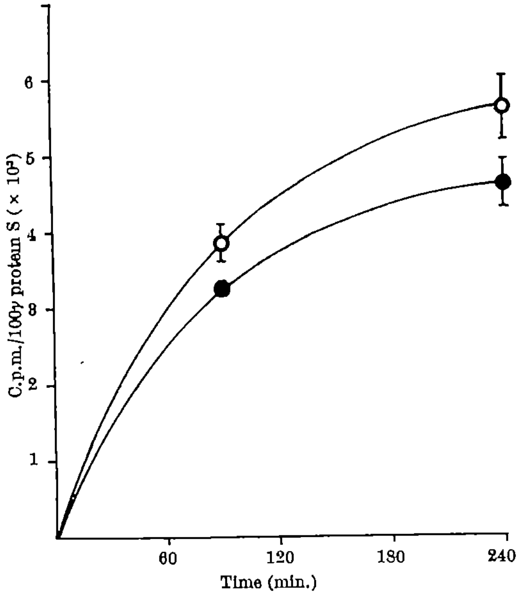

Fig. 1. Time course of ^{35}S-methionine incorporation into proteins of brain cortex slices in the presence (●) or absence (○) of MSI in the incubation medium. Slices were incubated in Krebs–Ringer phosphate-saline pH 7·4, containing glucose and ^{35}S-methionine, with or without MSI (10^{-2} *M*) at 37° C., gaseous phase oxygen. Curves are drawn through points corresponding to mean values of four independent experiments ± *S.E.*

sulphoximine (MSI) was obtained from the California Corporation for Biochemical Research, Los Angeles.

Following incubation, the protein fraction of brain cortex slices was obtained by the procedure described elsewhere[6]. Protein-bound sulphur was oxidized to sulphate, and then precipitated as benzidine sulphate, the radioactivity of which was measured in a Frieseke–Hoepfner scaler. The preparation of samples for the measurement of radioactivity and their further treatment has also been described in a previous report[6]. Results were expressed as c.p.m./100γ protein sulphur. Further details of experimental procedure are given in Table 1 and Figs. 1–3.

As can be seen from Table 1, the concentrations of MSI which are known to inhibit markedly proteosynthesis in other tissues *in vitro* (Ehrlich ascites carcinoma cells, liver, pancreas[7–10]) had no effect on ^{35}S-methionine incorporation into proteins of guinea pig brain cortex slices. Similar results were obtained with brain cortex slices of the rat and rabbit (Table 1). An increase in concentration of MSI to 10^{-2} *M* resulted in a slight inhibition of incorporation only. In the absence of substrate in the incubation medium, MSI failed to have any effect on the process investigated (Table 1).

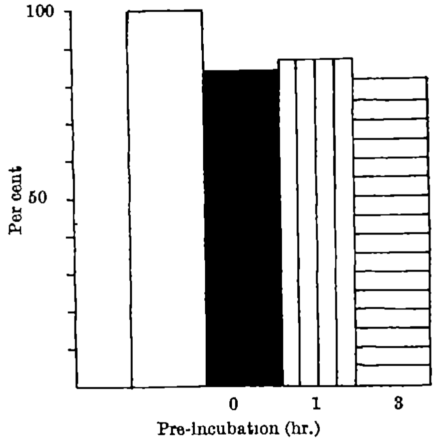

Fig. 2. Effect of pre-incubation of brain cortex slices with MSI on ^{35}S-methionine incorporation into brain proteins. Slices were pre-incubated in Krebs–Ringer phosphate-saline pH 7·4, containing glucose (10^{-2} *M*), with or without MSI (10^{-2} *M*) for 0, 1 or 3 hr and then incubated in the presence of ^{35}S-methionine for 90 min. at 37° C., gaseous phase oxygen. (The values of ^{35}S-methionine incorporation after the pre-incubation without MSI are expressed as 100 per cent; each column represents mean value of four independent experiments)

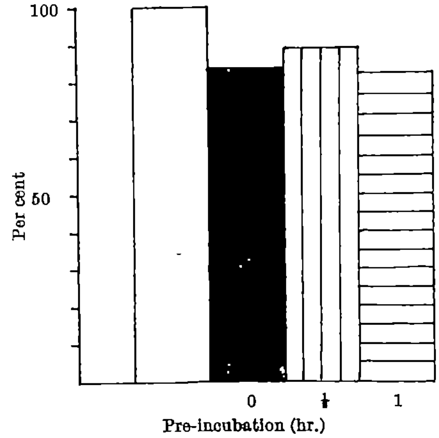

Fig. 3. Effect of pre-incubation of brain cortex slices in the absence of substrate upon MSI inhibition of ^{35}S-methionine incorporation into proteins. Slices were pre-incubated in Krebs–Ringer phosphate-saline pH 7·4, without glucose for 0, ½ or 1 hr. at 37° C. and then incubated in the presence of glucose, ^{35}S-methionine, with or without MSI (10^{-2} *M*) for 90 min. at 37° C., gaseous phase oxygen. (The values of ^{35}S-methionine incorporation in the absence of MSI are expressed as 100 per cent; each column represents mean value of four independent experiments)

Prolongation of the incubation period up to 4 hr. did not cause a further increase in the low degree of inhibition of incorporation (Fig. 1). Similarly, the pre-incubation of brain cortex slices with MSI did not influence further the inhibitory effect (Fig. 2).

Table 1. Effect of dl-Methionine Sulphoximine (MSI) on Uptake of Oxygen and ^{35}S-Methionine Incorporation into Proteins of Brain Cortex Slices

Animal	Concentration of MSI (*M*)	No. of exps.	c.p.m./100γ protein S	*P*	No. of exps.	μ*M*O$_2$/hr./gm. fresh tissue
Guinea pig	0	7	4,158±179		3	83·9±1·8
	2×10^{-3}	7	4,034±161		3	83·5±2·1
Guinea pig	0	8	3,269±210	<0 5	5	77·8±1·6
	4×10^{-3}	8	2,854±188		5	80 4±1·9
Rat	0	3	3,506±130			
	4×10^{-3}	3	3,680±183			
Rabbit	0	4	2,790±488		3	64 4±3 0
	4×10^{-3}	4	2,888±199		3	64·1±3·7
Guinea pig	0	5	3,800±209	<0·05	5	77·5±2 3
	10^{-2}	5	3,194±88		6	76·1±2·4
Guinea pig*	0	4	1,636±67			
	10^{-2}	4	1,594±145			

Slices were incubated in Krebs–Ringer phosphate-saline pH 7·4, containing glucose (without glucose*), ^{35}S-methionine, with or without MSI for 90 min. at 37° C., gaseous phase oxygen. Mean values ± *S.E.*, the number of experiments and statistical evaluation by *t*-test (*P*) are given.

When guinea pig brain cortex slices were pre-incubated in Krebs–Ringer phosphate-saline without substrate and then transferred to normal medium for incubation (Fig. 3), only a slight inhibition was also observed.

Preliminary experiments with homogenates of brain cortex tissue have shown that under these conditions MSI (4×10^{-3} *M*) failed to have any inhibitory effect on ^{35}S-methionine incorporation into proteins.

It follows from Table 1 that the uptake of oxygen by brain cortex slices in the presence of MSI concentrations used remained unaffected.

It is difficult to explain why MSI has little effect *in vitro* in spite of its inhibitory effect on ^{35}S-methionine incorporation into brain proteins *in vivo*. It seems that permeability phenomena are probably not the main factors involved. However, the possibility that, for example, some metabolic products of MSI are being formed in other tissues than the brain tissue cannot be ignored or that there is a connexion with the level of intracellular brain glutamine. These and other possibilities are under investigation.

Effect of Dimethylbenzanthracene on the Cellular Proliferation Cycle

THE carcinogenic hydrocarbon 7,12-dimethylbenz[α]anthracene (DMBA) inhibits the incorporation of tritiated thymidine into the deoxyribonucleic acid (DNA) of the cells of the growing hair follicle of the mouse to the extent of approximately 50 per cent in 24 hr.[1]. We have now examined the effect of this hydrocarbon on the timing of the phases of the proliferative cycle of these cells.

The animals used were females, 8–12 weeks old, of an inbred strain derived from Walter Reed Hospital Swiss mice. Hair was plucked from the back in order to stimulate cell division in the hair follicle[2]. Three days later, 0·15 ml. of 0·05 per cent DMBA in acetone was applied to 2 cm.^{2} of the plucked skin[3,4]. After 6 hr., when an effect on incorporation of the label could be expected[1], tritiated thymidine (50–100 μc., specific activity 3·9 c./m*M*) was injected intraperitoneally, and 1 hr.–24 hr. thereafter pairs of animals were killed. Small samples of the treated and adjacent untreated skin were fixed in ethanol/acetic acid (3 : 1). The skin was stained by the Feulgen procedure. The bulbs of individual hair follicles were then dissected and squashed. The slides were dipped in melted Kodak *NTB* emulsion, stored until suitably exposed, and developed. Mitotic figures (late prophase to early telophase) were scored for presence or absence of label. The results are recorded in Fig. 1.

The mean duration of the phase of DNA-synthesis (*S*-phase) and pre-mitotic G_2-phase[5] were estimated according to Quastler and Sherman[6]. G_2-phase occupied 1·5 hr. in both untreated and DMBA-treated follicles.

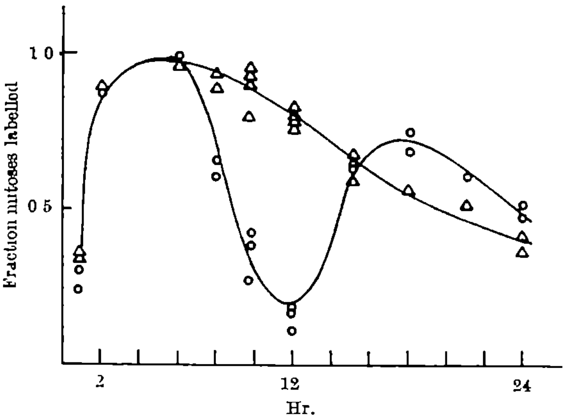

Fig. 1. Fraction of mitotic figures labelled in DMBA-treated (triangles) and untreated (circles) hair follicles of mice at different times after injection of tritiated thymidine. Each point derived from one mouse

In the untreated follicles, *S*-phase is about 7·5 hr. with a standard deviation of approximately 1 hr. The duration of the cell-cycle estimated from Fig. 1 is about 12 hr. These values agree closely with those obtained by Cattaneo *et al.*[7] in the growing hair follicle of *CF*-1 male mouse.

In contrast, the duration of *S*-phase in the DMBA-treated follicle is about 18·5 hr. with a standard deviation of approximately 9 hr. It is evident that DMBA has a marked but variable effect on cells synthesizing DNA.

The duration of mitosis was not measured, but it was evident that DMBA did not produce a block in mitosis, for the proportions of the various stages were not markedly changed in the treated cells.

In the animals which provided the data of Table 1, the fraction labelled cells/total cells was 57 per cent for control follicles and 65 per cent for treated. These values and those for the corresponding duration of *S*-phase provide a calculated mean duration of the cell-cycle of 13 hr. in the control (12 hr. from Fig. 1) and about 28·5 hr. for treated cells (cannot be estimated from Fig. 1).

Table 1. RELATIVE PROPORTIONS OF STAGES OF MITOSIS IN CONTROL AND DMBA-TREATED* GROWING HAIR FOLLICLES

Mouse		Prophase	Metaphase	Anaphase	Telophase
1	Treated	10	47	24	19
	Control	3	54	11	33
2	Treated	5	50	19	26
	Control	7	46	21	25
3	Treated	12	53	23	13
	Control	7	59	25	12

* 0 15 ml. of 0·05 per cent DMBA in acetone applied to 2 cm.^{2} of plucked skin. Animals killed 24 hr. later when percentage inhibition of incorporation of tritiated thymidine was: mouse 1 = 43, mouse 2 = 45, mouse 3 = 68

The uncertainty in the calculated duration of the generation time makes it impossible to decide if the post-mitotic phase (G_1) is affected by treatment with DMBA. The observation referred to here that the labelling index is somewhat higher (65 per cent) in the treated cells than in the untreated cells (57 per cent) shows that it is unlikely that DMBA produces a *block* in G_1. If cells were prevented from passing through G_1- into *S*-phase, fewer cells should be labelled in the treated than in the control follicles.

We conclude that cells of the growing hair follicle of this strain of mouse, treated with DMBA, are slowed in their passage through *S*-phase. The rate of passage is reduced to about the same degree as the rate of uptake of tracer into DNA[1]. There is no effect on the passage through G_2, and probably none on passage through G_1 and mitosis.

Response of the Hodgkin–Huxley Model to Temperature and Chemical Impulses

Tasaki *et al.*[1,2] have demonstrated the existence of prolonged action potentials in the squid axon under tetraethylammonium and of a "hyperpolarizing response" of the normal squid axon in enriched potassium solutions. In a series of experiments they have evaluated the properties of the squid axon membrane in these two particular environments and were led to the conclusion that the Hodgkin–Huxley[3] equations did not account for their observations, which had to be explained instead in terms of a "bi-stable state" hypothesis.

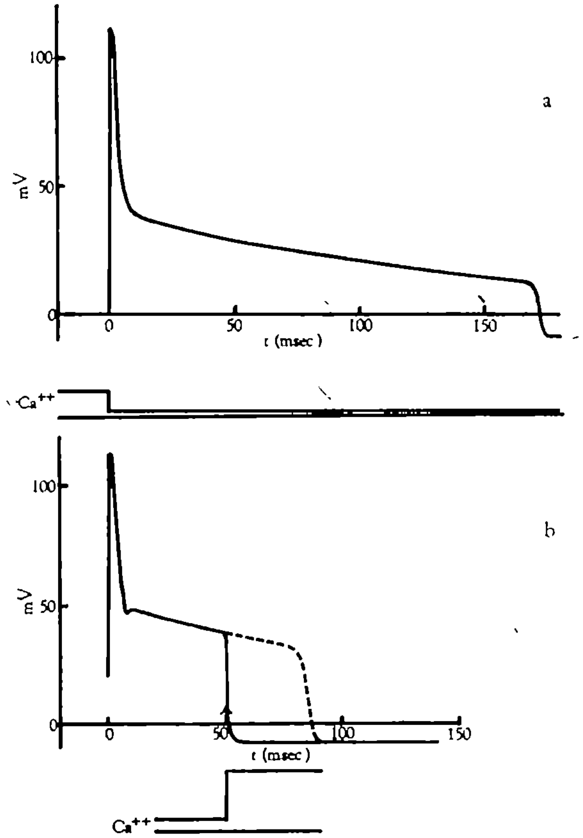

Fig. 1. Response of membrane with prolonged action potential to sudden changes of external calcium *a*, A five-fold reduction in [Ca]$_0$ initiates an action potential which is longer than normal; *b*, a five-fold increase in [Ca]$_0$ is seen to produce abolition

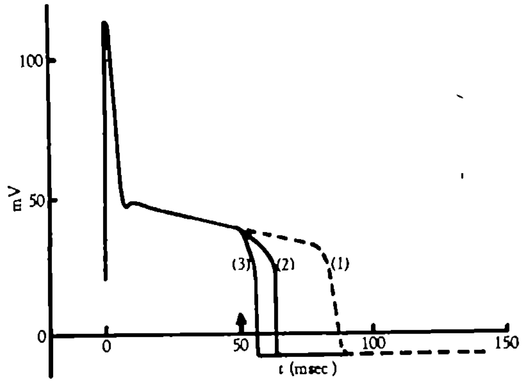

Fig. 2. Response of the Hodgkin–Huxley model to sudden increases of ambient temperatures. (1) Contact temperature; (2) $\Delta T = + 10°$ C. at $t = 50$ msec., (3) $\Delta T = + 20°$ C. at $t = 50$ msec.

In a recent communication[4] we demonstrated the existence of solutions of the Hodgkin–Huxley equations which correspond rather closely with the observations of Tasaki *et al.*, and that while the concept of a "bi-stable state" may form a useful aid to thought in considering action potentials in the squid axon under certain experimental conditions, it was in fact already implied in the Hodgkin–Huxley formalism. A similar conclusion had also been reached by Fitzhugh[5].

Recently, Spyropoulos[6] has published further findings on prolonged action potentials, this time on action potentials in frog node prolonged by the application of Ni^{++}. Spyropoulos has shown that a prolonged action potential may be initiated by a sudden reduction in the external Ca^{++} concentration, and may be abolished by a sudden increase in external Ca^{++}. Abolition may also be produced by sudden pulses of increased temperature.

Using the fast digital computer *Silliac*, we were therefore led to explore whether these responses also were consistent with the Hodgkin–Huxley equations and have found that they are.

Fig. 1, for example, shows the response to chemical pulses of Ca^{++}. The effect of changes in external calcium was simulated in the Hodgkin–Huxley equations by a prescription already used by Huxley[7], namely, to alter the voltages in the Hodgkin–Huxley equations involving the sodium and potassium current carriers by an amount:

$$\Delta V. = k \log[Ca]_0/[Ca]_i$$

where k was so adjusted such that a 5-fold change in [Ca]$_0$ corresponded to $\Delta V. = -15$ mV., as had been shown previously by Frankenhaeuser and Hodgkin[8].

Fig. 1*a* shows that a 5-fold decrease of [Ca]$_0$ will produce a response in a membrane satisfying the Hodgkin–Huxley equations and Fig. 1*b* that a 5-fold increase of [Ca]$_0$ will switch it off.

As in our previous computations[4], the prolonged action potentials were produced by slowing down the potassium current carrying mechanism by a factor of one hundred times.

The effect of a sudden increase in temperature is shown in Fig. 2. It is seen that the prolonged action potential in a Hodgkin–Huxley membrane is abolished by a rise in temperature of 10° C. and even more rapidly by an increase in temperature of 20° C.

Ageing and Environmental Manifestations in Pyruvate Metabolism of Rabbit Fœtal and Neonatal Liver

Fœtal and perinatal cell differentiation may be considered as a sequence of progressive metabolic alterations determined in part by genetic and in part by environmental influences. Implied in genetically organized differentiation are the biological processes of maturation, growth and senescence which are collectively referred to as the ageing of the cell.

In an effort to distinguish between metabolic activity related to environmental needs as contrasted with the requirement of the ageing process, the following investigation was carried out.

Pregnant rabbits were rendered post-mature by subcutaneous injection of 40 units/kgm. 'Antuitrin-*S*' (kindly supplied by Dr. L. T. Blouin, Parke, Davis Laboratories, Ann Arbor) at 24 days of gestation. The litters were delivered by Cæsarian section 4 days after the calculated day of confinement. In a second group of untreated rabbits, spontaneous delivery occurred at term and in a third group, term-delivered litters were allowed to be breast-fed for four days. Fœtus and new-born were killed by decapitation and the livers placed immediately in ice-cold isotonic sodium chloride. Following a previously described technique[1], liver slices 0·3–0·5 mm. thick were incubated with 30 μmoles of pyruvate-2-^{14}C in a Warburg respirator for 2 hr. in 100 per cent oxygen. Oxygen consumption, glycogen utilization, pyruvate utilization and production, conversion of labelled substrate to $^{14}CO_2$ and production of lipids and lactate were measured[1] and the results expressed per gram tissue dry weight. The data obtained were statistically analysed by Student's *t* (ref. 2).

In the 4-day-old rabbit, the liver utilized 112 per cent more oxygen, 61 per cent more pyruvate and produced 100 per cent more labelled respiratory $^{14}CO_2$, but formed only one-third as much lipid and contained only 32 per cent of the glycogen as compared with new-born liver. Post-mature rabbit liver utilized 75 per cent more oxygen, 63 per cent more pyruvate and converted 122 per cent more labelled substrate to respiratory carbon dioxide than new-born liver. On the other hand, post-mature liver consumed 18 per cent less oxygen, utilized the same amount of pyruvate and converted 10 times more labelled substrate to lipids as compared with 4-day-old liver. Net lactate production was higher in the 4-day old post-mature liver than in the liver of the 4-day-old and of the new-born. Glycogen content of post-mature liver was not statistically different from that in the 4-day-old liver.

Table 1. *In vitro* Incubation of Rabbit Liver Slices at Different Stages of Development with Pyruvate-2-^{14}C

	4-day-old	New-born	4-day post-mature
	μmoles/gm. tissue dry weight ± *S.E.*		
Oxygen utilization	*434 ± 21 (10)	204 ± 16 (10)	†357 ± 19 (15)
Glycogen content	*92 ± 87 (10)	290 ± 97 (6)	*64 ± 20·4 (8)
Utilized glycogen	*99 ± 26 (14)	236 ± 19 (11)	*44 ± 10 (10)

Lactate production	86·3 ± 7 (11)	82 ± 12 (11)	*113 ± 5 (11)

No. of determinations given in parentheses.
*$P < 0·05$ when compared to the new-born.
†$P < 0·05$ when compared to the 4-day-old.

Oxidation of pyruvate-2-^{14}C to respiratory carbon dioxide, pyruvate utilization and tissue oxygen consumption permit an estimate of the overall rate of cellular oxidative metabolism.

Our results indicate that pyruvate oxidative metabolism is twice as active in the 4-day-old rabbit liver than in the new-born. Since in the post-mature rabbit liver, the pyruvate oxidative metabolism is comparable to the 4-day-old liver, the characteristic metabolic determinants which support total oxidative metabolism *in utero* are functions of the ageing process of the fœtal liver cell and not of the environment.

In contrast to these findings, conversion of pyruvate to lipids, hepatic glycogen content and the rate of glycolysis are influenced by environmental factors. Thus, the liver of the new-born and of the post-mature has a higher rate of lipid synthesis than that of the 4-day-old. Dawkins[3] has demonstrated in the neonatal liver of the same animal that glucose-6-phosphatase activity increases as a result of environmental factors. Therefore, the liver of the 4-day-old has a lower glycogen content than that of the new-born.

The glycogen content of the post-mature is as low as that of the 4-day-old. As the glucose-6-phosphatase does not increase in the post-mature fœtus[3], the reason for this low glycogen content is that the post-mature fœtus is hypoxic[4] and the resistance to hypoxia has been shown to depend in part on the rate of glycolysis[5] in the fœtal tissue. The higher rate of lactate production (31 per cent) supports this assumption. The post-mature converts pyruvate to lipids at a rate 10 times as high as the 4-day-old and 3 times as much as the new-born. This is another indication of hypoxia as lipid synthesis could represent an adaptive mechanism for the conservation of oxygen.

Inhibition of Histamine Formation *in vivo*

Quantitative studies of the inhibition of histidine decarboxylase *in vivo* are now feasible with the introduction of two methods of assessing the rate of endogenous histamine formation in the rat. One method, devised by Schayer, measures the amount of ^{14}C-histamine excreted in the urine following the injection of a known amount of ^{14}C-histidine. The other method depends on the demonstration that in the female rat the urinary excretion of free histamine parallels the endogenous formation of the amine[1,2]. Using both these methods, it was found that omitting pyridoxine from the diet for a week causes a reduction in histamine formation to about half normal, and that the rate of formation can be reduced further by superimposing injections of semicarbazide on the pyridoxine-deficient diet[3].

In the present work α-methyl-histidine was found to be a more specific and less toxic inhibitor of histamine formation than semicarbazide, which is known to inhibit a variety of enzymes, among them various amino-acid decarboxylases and diamine oxidases. α-Methyl-histidine was provided by Merck, Rahway, New Jersey, through the kind office of Dr. Schayer. This compound was tested in two types of experiments. One group of rats was fed the standard, adequate, histamine-free diet[1]. In another group pyridoxine was omitted from the diet until a reduced steady level of histamine formation was obtained, and α-methyl-histidine administered while the deficient diet was maintained. This was done to see whether inhibition of histamine formation by this compound was due to interference with the active centre of histidine decarboxylase or merely to an action on the co-enzyme pyridoxal-5-phosphate, the probable mode of action of semicarbazide. In addition, the urinary excretion of 5-hydroxyindolyl acetic acid (5-HIAA), which is believed to reflect the rate of endogenous formation of 5-hydroxytryptamine (5-HT), was followed. This, again, was carried out to see if α-methyl-histidine also inhibits the formation of 5-HT, which is known to result from hydroxylation of tryptophan to 5-hydroxytryptophan and the subsequent decarboxylation of this amino-acid.

Typical results in a rat fed the adequate diet are shown in Fig. 1; α-methyl-histidine injected under the skin in doses of 200 mgm./kgm., 4 times daily during four days, results in a reduction of the over-all formation of histamine, as determined by the urinary excretion, to less than half normal. On discontinuing the injections the original level of histamine formation is promptly restored and even transitory rebounds above this level are seen. The excretion of 5-HIAA, by contrast, remains unaltered.

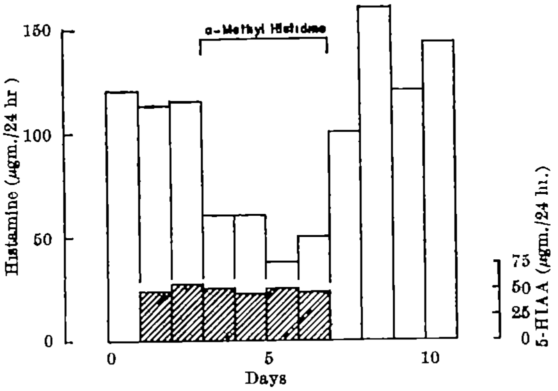

Fig. 1. The white columns represent amounts of daily excretion of free histamine in a female rat fed an adequate histamine-free diet. The hatched columns represent daily urinary excretion of 5-HIAA. α-Methyl-histidine was injected for a period of four days. Aminoguanidine was administered during the entire course of observations to prevent the inactivation of histamine by histaminase

In the group of rats on deficient diet, in a typical example, deficiency in pyridoxine for 24 days reduced the level of urinary histamine to about 40 per cent of normal, whence it remained steady for the period of observation. Superimposing injections of α-methyl-histidine on the maintained deficient diet, 4 × 200 mgm./kgm. daily for 4 days, beginning at the 24th day of deficiency, precipitated a further reduction in the formation of histamine to about half the level prevailing after 24 days of only pyridoxine deficiency. On cessation of the injections the level of urinary histamine promptly rose to the level at which administration of the inhibitor was begun. In the same group of rats ^{14}C-histidine was injected and the urinary ^{14}C-histamine measured, first on adequate diet, then at the reduced steady level of pyridoxine deficiency, and finally under conditions of superimposed injections of α-methyl-histidine on the deficient diet. The results with the radioactive method were the same as with the simpler one used simultaneously. Here again, injections of the inhibitor significantly reduced the ^{14}C-histamine excretion in the period when the deficiency of pyridoxine alone did not cause any further reduction in the formation of histamine. In these experiments α-methyl-histidine appears to act directly on the enzyme centre and not on the co-enzyme pyridoxal-5-phosphate, particularly because it does not inhibit the formation of 5-HT, as indicated by the excretion of 5-HIAA, to the production of which amine pyridoxal-5-phosphate is known to be a co-enzyme.

Injections of α-methyl-histidine in the amounts stated did not cause detectable psychical or physical ill effects, this in contrast to semicarbazide superimposed on the deficient diet which may elicit states of hyperirritability and panic, and in varying degrees a general deterioration of the physical state of the animal.

Finally, the effects of α-methyl-3,4-dihydroxyphenylalanine (α-methyl-DOPA) were similarly examined. In rats on adequate diet this compound in doses of 100–200 mgm./kgm., injected 4 times daily for four days, caused slight (about 25 per cent), or inconsistent, reductions in urinary histamine. In cases where the inhibition was definite, the urinary excretion of 5-HIAA was reduced to about the same extent as urinary histamine. Injections of α-methyl-DOPA caused prostration, diarrhoea, loss of appetite and body-weight.

In conclusion, α-methyl-histidine appears a promising weapon in further investigations of the physiology of histamine.

HÆMATOLOGY

A Direct Relationship between Adenosine Triphosphate-level and *in vivo* Viability of Erythrocytes

Although Loehr *et al.*[1] described in 1959 that adenosine triphosphate content (ATP) in erythrocytes decreased gradually during their life-span of 120 days on the average in blood vessels and suggested that the drop of the ATP-level caused destruction of erythrocytes *in vivo*, no concrete evidence for this theory has yet been presented.

Recently, some of the authors demonstrated that ATP increased rapidly through incubation with adenine and nucleoside in the erythrocytes which had been preserved for a long period[2,3], even when the addition of inosine alone was no longer effective. With the aid of this method of ATP regeneration, it was found that there was an intimate relationship between ATP-level in the erythrocytes and their shape[4,5]. In this communication, evidence will be presented concerning the relationship between ATP-level and *in vivo* viability of erythrocytes obtained by the same method as already described[4,5,11].

Acid-citrate-dextrose (ACD) blood collected from healthy volunteers was divided into three portions, to one of which one-tenth volume of physiological saline containing 12·5 µmoles/l. of adenine and 25 µmoles/l. of inosine was added (*B*) and nothing to the other two (*A*, *C*). After storage for eight weeks at 4° C. aseptically, the specimen *A*, preserved without any addition, was incubated with 12·5 µmoles/l. of adenine and 25 µmoles/l. of inosine for 2·5 hr. at 37° C. and then ATP content of the erythrocytes was estimated by Cohn and Carter's method[6]. The osmotic fragility was tested according to the median corpuscular fragility method[7]. Hexokinase activity in hæmolysate and utilization of glucose were determined according to the method of Kashket *et al.*[8]. Post-transfusion viability was determined by the method using chromate labelled with chromium-51. The shape of erythrocytes was observed with an ordinal light microscope using hanging-drop preparations.

After incubation with inosine and adenine ATP in the specimen *A* was regenerated to almost normal level, accompanying change of the shape from smooth sphere to discoidal, as reported before[2,3]. But the treatment had no effect on the osmotic fragility and hexokinase activity (Table 1). These results indicate that the damage to the enzyme activity, which occurred during storage, did not recover at all even when a great amount of ATP was regenerated. However, rather unexpected results were obtained on the post-transfusion viability of the erythrocytes as indicated in Fig. 1. The treatment with inosine and adenine showed a great deal of improvement on the post-transfusion viability of the erythrocytes preserved for a long period of time. These data were exactly reproducible through several series of experiments, although results of a single experiment alone are demonstrated in Table 1 and Fig. 1.

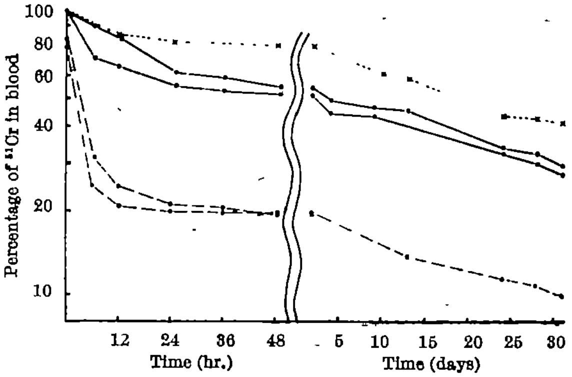

Fig. 1. Decay of radioactivity in circulating blood after transfusion of erythrocytes stored for eight weeks and labelled with radioactive chromate. Radioactivity of the blood 5 min. after the transfusion was represented as 100 per cent. ●—●, Erythrocytes stored in ACD and then incubated with inosine and adenine at 37° C. (specimen *A*); ×---×, erythrocytes stored in ACD containing inosine and adenine (specimen *B*); ●– – ●, erythrocytes stored in ACD alone (specimen *C*)

Table 1. Various Characteristics in the Erythrocytes treated with Inosine and Adenine after Preservation in ACD for Eight Weeks at 4° C.

	A Preserved in ACD without any addit. and then incubated with inosine and adenine	*B* Preserved in ACD with inosine and adenine	*C* Preserved in ACD
ATP µmoles per 100 ml. of cells	77	89	5 9
Osmotic fragility NaCl per cent at 50 per cent hæmolysis	0 66	0·49	0 61
Shape	discoidal	discoidal	smooth sphere
Hexokinase activ. in hæmolysate	127	206	124
Glucose utilizat. in cells, µgm /40 min 10·5 ml. blood	51	61	31

The results obtained emphasize a direct interrelationship between ATP content and a moment of *in vivo* destruction of the erythrocytes according to the following reasons.

(1) Although incubation with inosine and adenine resulted in no improvement either of hexokinase activity or of osmotic fragility, indicating that an irreversible change proceeded during storage, the reversal of post-transfusion viability was observed in association with the marked regeneration of ATP and the reversal of the shape of the erythrocytes. As the shape of erythrocytes depends on the ATP content in the cells as stated before, the great flexibility in shape of erythrocytes was observed even after eight weeks' storage. The viability seems to be essentially based not on the shape but on the ATP-level.

(2) The single addition either of inosine or of adenine to the erythrocytes, which had been stored in ACD solution for a long period of time, did not restore the ATP-level at all as reported before[3]. Furthermore, the preservation of erythrocytes in ACD solution containing either an adequate amount of inosine or adenine could maintain the ATP content and post-transfusion viability far less than that in ACD containing both of them[9-11]. These facts indicated that the effect of the treatment with inosine and adenine was not due to the mere presence of inosine or adenine itself, but to the metabolites derived from inosine and adenine. The metabolites related to inosine and adenine, which are generally accepted to be present in erythrocytes, are adenine nucleotides, hypoxanthine, inosine monophosphate, lactate, pyruvate, and phosphate esters which belong to the Warburg–Dickens and Embden–Meyerhof systems. The last five substances, however, could be demonstrated even in the erythrocytes incubated with inosine alone[12]. Recently, some of the authors presented evidence that the adenine nucleotide, especially ATP in the preserved erythrocytes, definitely regenerates through

incubation with inosine and adenine, and also a presumable pathway, by which the ATP regeneration may proceed during incubation, was advocated[13]. Now, an accumulation of results of our previous and recent experiments lead us reasonably to conclude that the ATP-level is most likely to be responsible for reversal of the post-transfusion viability of the preserved erythrocytes.

Thus, the organism may distinguish deteriorated erythrocytes from younger or vital cells not by their mechanical fragility, but by adenosine triphosphate-level in the erythrocytes. presumably mediated by the changes of still undetermined nature, which probably occur at the surface of the erythrocytes. These results also suggest an existence of an intimate and rather direct relationship between adenosine triphosphate-level and erythrocytes integrity.

Conditions Influencing the Stability of Human Antihæmophilic Factor

The lability of human antihæmophilic factor in both plasma and concentrates is a major hazard during purification, even when the reaction of solutions is maintained within the rather restricted optimum range of stability, which we find to be *p*H 7·1–7·2, and when preparative procedures are conducted at temperatures close to 0°.

Antihæmophilic factor is carried down with the fibrinogen fraction when this is separated from fresh normal human plasma. In addition the fibrinogen fraction, among other contaminants, contains plasminogen, and the separation of antihæmophilic factor from fibrinogen and plasminogen is a matter of some difficulty.

When solvents such as ethanol[1] or diethyl ether[2] are used to fractionate plasma proteins, small quantities of an actively fibrinogenolytic substance, probably plasmin, tend to be present in partially purified fibrinogen preparations. The presence of this fibrinogenolytic agent is manifested by the eventual loss of the ability of solutions of fibrinogen, after prolonged incubation under standard conditions, to form a clot when samples are added to a solution of thrombin. Concentrates of human antihæmophilic factor, which we have made by a modification of the method of Kekwick and Wolf[3], contain traces of this fibrinogenolytic agent, of the order of 0·001 Loomis fibrinolysin units/ml. Since Wagner, Brinkhous and Penick[4] have shown that canine antihæmophilic factor is destroyed rapidly by bovine plasmin, it was of interest to see whether the stability of human antihæmophilic factor concentrates could be enhanced by adding ε-aminocaproic acid, which is known to inhibit plasmin activity[5].

From the results presented in Table 1 it can be seen that 0·05 and 0·10 *M* ε-aminocaproic acid had no significant influence on the stability of the antihæmophilic factor in a concentrate although the fibrinogenolytic activity was reduced to 20–25 per cent of the initial level. With one preparation the stability of the antihæmophilic factor was slightly improved with 0·1 *M*, but an increase in the amount of ε-aminocaproic acid to 0·4 *M* caused no further improvement. When the concentrate (Table 1) was treated with 0·002 *M* di-isopropyl-phospho-fluoridate (DFP) there was no detectable decrement in antihæmophilic factor activity after 7 hr. and 92 per cent of the activity remained after 24 hr. incubation at 25°. The antihæmophilic factor activity of the test solutions was adjusted to be approximately equivalent to that of fresh normal human plasma, in a citrate–phosphate–saline buffer *p*H 7·2, *I* 0·30.

Table 1. Effect of ε-Aminocaproic Acid and Di-isopropyl phospho-fluoridate on the Stability of Human Antihæmophilic Factor (AHF) in Concentrates

Sample	ε-Amino-caproic acid (*M*)	Percentage AHF remaining after 7 hr. at 25°	Fibrinogen life (hr. at 37°)
Original concentrate	0 00	64	30
,, ,,	0 05	64	168
,, ,,	0 10	60	110
DFP-treated concentrate	—	100 (92 after 24 hr.)	—

The AHF activity was assayed in a thromboplastin generation test based on that described by Pool and Robinson (ref. 6).

The fibrinogen life. Solutions of a fraction containing 0·2 gm. protein/100 ml. in veronal saline *p*H 7·3 *I* 0 15, with other additions as indicated, were incubated at 37°. The fibrinogen life is the period of incubation for which the solution retained the ability to form a clot when 0 20 ml. was added to 0 20 ml. thrombin solution. Clotting time of samples at beginning of incubation about 10 sec. The fibrinogen content of all the fractions was about 70 per cent of the total protein.

When another antihæmophilic factor concentrate obtained as a precipitate was extracted at 0° with a citrate–phosphate buffer *p*H 7·2 *I* 0·15, the total protein was about equally divided between the extract and residue, but 90–95 per cent of the antihæmophilic factor activity remained in the residue. Despite the fact that most of the fibrinogenolytic activity also remained in the residue, the stability of the antihæmophilic factor in it was much higher than in the original concentrate. Thus under the conditions of testing, after 7 hr. incubation at 25°, 97 per cent of the antihæmophilic factor activity was present in solutions of the residue whereas only 74 per cent of the antihæmophilic factor activity remained in solutions of the original concentrate (Table 2). When the residue and the extract were mixed in the original proportions, the stability of the antihæmophilic factor was effectively the same as in solutions of the starting material. However, when the extract was treated with DFP, and the excess of this removed by dialysing before mixing the DFP-treated extract with the residue, the stability of the antihæmophilic factor in this mixture was the same as in solutions of the residue alone (Table 2).

Table 2. EFFECT OF TREATMENT OF CONCENTRATE AND EXTRACT WITH DI-ISOPROPYL-PHOSPHO-FLUORIDATE ON THE STABILITY OF AHF IN THE CONCENTRATE AND MIXTURES OF THE EXTRACT AND RESIDUE

Sample	Percentage AHF remaining after 7 hr. at 25°	Fibrinogen life (hr. at 37°)
Original concentrate	74	130
Residue	97	76
Extract	—	> 130
Residue + extract	70	—
Original concentrate treated with DFP	96	—
Residue + DFP-treated extract	94	—

See footnotes to Table 1.

These results suggest that the instability of human antihæmophilic factor in solutions of concentrates is largely due to the action of a DFP-sensitive component other than plasmin; the nature of this component is under investigation. The enhanced stability of antihæmophilic factor in DFP-treated concentrates should facilitate further purification.

Fuller details of this work, for the support of which we are indebted to the Medical Research Council, will be published elsewhere.

HISTOCHEMISTRY

Effect of 3-Methylcholanthrene Crystals and Solutions on the Chorioallantoic Membrane of the Developing Chick Embryo

METAPLASTIC changes of the chorioallantoic membrane of the developing chick embryo, such as keratinization and epidermoid pearl formation, have been reported by several authors[1-4].

We have subjected the chorioallantoic membrane of chick embryos of various ages to single topical applications of crystals of 3-methylcholanthrene as well as to various concentrations of the carcinogen dissolved in acetone or polyethylene glycol. In order to determine the effects of carcinogen *per se*, the vehicles alone, as well as particles of egg-shell, have also been tested.

The results so far have shown that the response depends in part on the age of the embryo. After initial necrosis and inflammation, the most impressive reaction of the chorionic ectoderm was metaplasia, such as stratification of epithelium and of prickle cell, keratin and epithelial pearl formation. An additional reaction seen in 10-day chorioallantoic membranes subjected to methylcholanthrene crystals was the presence of cords, columns and clusters of epithelial cells deep in the mesenchyme. Such accelerated response under similar conditions of embryonic age was not noticed with the application of the non-carcinogenic irritant.

The egg-shell powder produced a characteristic foreign-body giant cell response.

PATHOLOGY

Urinary Phenolic Acids in Infective Hepatitis

AN abnormal urinary excretion of aromatic metabolites of tyrosine (that is, tyrosyluria) is well known to occur in scurvy. Recently, Robinson and Smith[1,2] reported tyrosyluria in severe stress (spinal shock, burns, etc.) and various pathological conditions, in patients receiving an adequate dietary intake of ascorbic acid.

Since tyrosine is metabolized in the liver, it seemed worth while examining the urines of patients suffering from parenchymatous liver damage for tyrosine metabolites.

Urine specimens were collected over a period of 24 hr. from 6 patients suffering from infective hepatitis. All the patients had increased serum glutamic-oxalacetic transaminase activities, reduced serum albumin concentrations and raised thymol turbidities. Their dietary intake of ascorbic acid was adequate.

The urinary phenolic acids were extracted by the method of Hill *et al.*[3]. A quantity of extract equivalent to the volume of urine passed in 1 min. was subjected to two-dimensional paper chromatography using isopropanol–ammonia followed by *n*-butanol–pyridine–water[3]. After drying, the chromatograms were sprayed with 10 per cent sodium carbonate solution, dried again and resprayed with diazotized sulphanilic acid. Hydrolysed urine samples were not examined.

Using this technique, *p*-hydroxyphenylacetic acid is almost invariably found in small quantities in normal urine, but *p*-hydroxyphenyllactic acid is rarely detected.

All six patients suffering from infective hepatitis excreted increased amounts of both *p*-hydroxyphenylacetic and *p*-hydroxyphenyllactic acids. A seventh patient with hepatic cirrhosis also excreted increased amounts of these phenolic acids. None of the patients excreted significantly increased amounts of 4-hydroxy-3-methoxymandelic acid.

It seems probable that parenchymatous liver damage can be the commonest cause of tyrosyluria. The question arises whether the tyrosyluria which Robinson and Smith[1,2] observed in stress and in various pathological conditions was due to some degree of liver dysfunction. This is being investigated. Preliminary results show that in myocardial infarction this is probably true.

Cell Turnover in Pulmonary Tissues

In recent years considerable interest has been shown in the turnover of epithelial cells, particularly those in the gastro-intestinal tract[1,2]. These investigations have been facilitated by the introduction of autoradiographic techniques and the use of tritium-labelled thymidine. This is incorporated specifically by the nuclei of cells in pre-mitosis, at which time synthesis of deoxyribonucleic acid (DNA) is occurring[3].

Bertalanffy and Leblond[4] reported their findings in an investigation of cell turnover in the lung in the albino rat, in which they used the technique of mitotic counting after colchicine arrest; but extensive search of the literature has not revealed any other studies on the pattern of cell turnover in pulmonary tissue.

This communication records the findings of an investigation into turnover of the cells in mouse lung using tritium-labelled thymidine and autoradiography. It has been assumed that the labelled cells behave in the same way as normal cells although it is possible that the use of tritium-labelled substances may result in modification of the DNA molecule[5].

18-day albino mice were used. 100 μc. of tritium-labelled thymidine (Atomic Energy Research Establishment, Harwell; 100 mc./m*M*) in 0·2 ml. saline were injected intraperitoneally into each animal at 11 a.m. on the first day of the experiment. Afterwards the animals were maintained in free-run cages with full access to chow and water. Paired animals were killed by ether anæsthesia at intervals of 1, 6, 24, 48, 72 and 96 hr. after injection and further pairs after 1 week, 10 days and 3 weeks respectively.

The trachea and lungs were dissected immediately and fixed in 10 per cent formalin solution. Paraffin-embedded sections of whole lungs were cut to include parts of the main bronchi and autoradiographs were prepared using stripping-film technique (Kodak; *AR*10). After exposure for one month, and developing, the sections were stained with neutral red. All the slides were examined by light microscopy.

1 hr. following injection it was found that only scattered epithelial cells in the large bronchi showed nuclear labelling. The labelled cells were situated mainly, but not exclusively, in the basal layer of the bronchial epithelium. The superficial cells showing labelling at 1 hr. were no longer present at 3 days.

Over the three-week period of observation the labelled cells in the basal layer showed migration towards the surface of the epithelium. Very occasional labelled cells, however, were still present at the end of this time. In the small bronchi and respiratory bronchioles only scattered, labelled epithelial cells were seen at 1 hr. Turnover was faster than in the large bronchi and no labelled cells were present at 10 days.

With the techniques used it was clear that the scattered, labelled cells seen in the walls of pulmonary alveoli were macrophages. It was impossible, however, accurately to differentiate histologically between the vacuolated and non-vacuolated forms described by Bertalanffy and Leblond[4].

At 7 days the labelled cells showed an abrupt decrease, but thereafter the appearances remained roughly constant with, at 3 weeks, very occasional cells still showing labelling. There was no evidence of shedding of labelled cells into alveolar spaces in any of the sections.

In the pleural tissues scattered mesothelial cells showed labelling at 1 hr. While occasional cells still showed labelling at 10 days, none was evident at 3 weeks.

It is apparent, therefore, that unlike the widespread uptake of tritium-labelled thymidine shown by gastro-intestinal epithelium, the uptake by respiratory epithelium is limited to scattered cells. This low degree of mitotic activity and slow turnover of cells may be related to the fact that, under normal conditions, respiratory epithelium is not exposed to significant amounts of trauma, nor is it called on to secrete large quantities of enzyme, as is the situation, for example, in the small intestine. It is also of interest to find that, contrary to orthodox opinion, mitosis is not confined to cells in the basal layer of bronchial epithelium but also occurs in the intermediate and superficial layers.

From our observations we have concluded that the turnover time for epithelial cells in the small bronchi and respiratory bronchioles is 7–10 days. In the large bronchi it was apparent that the superficial cells showing labelling at 1 hr. had a shorter life-span (3 days) than the overall figure of 3 weeks while occasional basal cells had a longer life-span, since labelling was still present at 3 weeks. These epithelial cells with greater and lesser life-span did not differ histologically from those epithelial cells with a turnover time of 3 weeks.

In the pulmonary alveoli, despite the failure to make a histological differentiation between vacuolated and non-vacuolated macrophages with the techniques used, the marked decrease in labelled cells at 7 days indicated that the majority of these macrophage cells had a life-span of approximately 7 days. It is considered that these probably corresponded to non-vacuolated macrophage cells which were estimated by Bertalanffy and Leblond[4], using mitotic counting, to have a life-span of 8 days. The alveolar cells showing labelling after 7 days later proved to have a life-span in excess of 3 weeks. These probably represented vacuolated macrophages which Bertalanffy and Leblond[4] estimated to have a life-span of 29 days.

ANATOMY

Significance of Arachnoidal Cell Clusters in Man

Since the early part of this century arachnoidal cell clusters in man have generally been accepted as a manifestation of advancing age. They were first described by Meyer[1] as a post-mortem finding in the meninges of patients suffering from mental disease. It has since become evident that they occurred not only in man but also in various laboratory animals[2,3]. Their association with advancing age can be attributed largely to the work of Weed[4], who, in a series of cats of

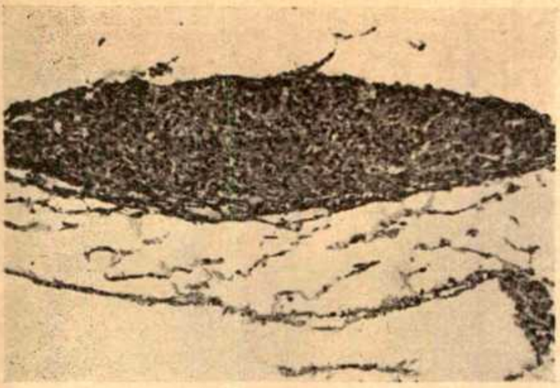

Fig. 1. An arachnoidal cell nest in the human fœtus. (× 107)

different ages, reported that in very old animals the cell clusters were always present, while in very young animals they were never found.

In man, however, arachnoidal cell proliferations can be found even in the unborn human fœtus and hence factors other than those of old age must be considered in their ætiology.

In a series of post-mortems on infants, 'milk-spots' in the meninges of the brain were observed in nearly two-thirds of all stillbirths and in about one-third of all neonatal deaths. They were more frequent in full term infants but were noted even in premature previable fœtuses. The histological features varied from typical arachnoidal cell clusters (Fig. 1) to a more fibrous structure sometimes containing capillary vessels and often showing degenerative changes. The example illustrated is from a stillborn fœtus (body-weight 3,350 gm.) that died of birth trauma.

The significance of these cell clusters in the human fœtus is uncertain. It has been shown experimentally that under conditions of anoxæmia the cells of the arachnoid do proliferate and form cell clusters as well as freely wandering macrophages[5]. Such a mechanism could certainly operate *in utero*, but it is likely that other factors are also involved. In any event, it would seem unnecessary at present to postulate that the human species may be afflicted with old age even from before birth.

IMMUNOLOGY

In vitro Synthesis of Auto-Antibodies by Rabbit Lymph Node Cells following Cross-Immunization *in vivo*

CROSS-reactions between phylogenically related antigens with an immune serum produced in an animal immunized with a substance similar to these antigens is a familiar concept. The idea that this cross-reaction could extend to self-substances of the immunized animal is not so widely accepted, although there are no essential differences between the cross-reactions involving two foreign substances or the cross-reaction between one foreign and one autologous substance. If auto-antibodies can be synthesized in certain circumstances of immunization (that is, by a mammal immunized with antigens of another species of mammal) then, *in vivo*, in the spectrum of different antibody molecules synthesized in response to the stimulation, those which will bear an antibody specificity complementary to self-substances will immediately disappear.

On the other hand, tissue culture conditions open new opportunities to detect the synthesis of such auto-antibodies since the auto-antigen is not necessarily present in the culture.

In vitro synthesis of anti-erythrocytes antibodies, by lymph-node cells of rabbits, in a stage of secondary response, has been followed by a technique described previously[1]. Sheep erythrocytes were injected in the foot-pad of rabbits and the popliteal lymph nodes were taken three days after a booster injection. All suspensions were made in Parker's medium 1066 supplemented with bovine amniotic fluid, with or without normal rabbit serum, depending on the experiment. All lymph-node cell suspensions were started with 10^7 cells/ml. fluid. In a few experiments small washed fragments (about 1 mm.^{3}) were used instead of cells. A mixture of carbon-14-labelled valine, leucine, lysine and threonine was added to the medium. The tissue culture fluids, obtained after short-term survival experiments (one or two days), were studied for their content in radioactive material precipitable by trichloroacetic acid or in radioactive material susceptible to be fixed on different erythrocytes. Three kinds of erythrocytes have been used: the homologous antigen sheep erythrocytes and cross-reacting antigens; normal rabbit erythrocytes or rabbit erythrocytes taken from the donor of the lymph node cells. It is thus possible to observe three kinds of antibody specificity: heterospecificity (of rabbit antibody towards sheep erythrocytes), isospecificity (of rabbit antibody towards normal rabbit erythrocyte) and auto-specificity (of rabbit antibody against its own erythrocytes; rabbit erythrocytes taken from the donor of the lymph node cells).

Our tracer results show that surviving cells can synthesize antibodies; the evidence that we are dealing with true antibodies being principally of two kinds: agglutination of rabbit red cells by the tissue culture medium and fixation of radioactivity on the red cells.

Agglutination has been performed with a micro-technique[2] using small concentrations of red cells (10^7/ml.) and microscopic examination. This micro-technique markedly increased the sensitivity of the detection. We have observed that, in most cases, antibodies agglutinating sheep erythrocytes, normal rabbit erythrocytes, and rabbit erythrocytes taken from the donor of the lymph node cells could be detected in the tissue culture fluid. Sometimes, this agglutination could be followed up to a final dilution of 1/80 for 10^7 cells, the end point of the reaction being given by the presence of occasional clusters of 2 or 3 cells clumped in the microscope field. Tissue culture fluids from non-immunized rabbits never showed any agglutinating activity.

By incubation with tissue culture fluid, radioactive material is fixed on sheep erythrocytes, normal rabbit erythrocytes and rabbit erythrocytes taken from the donor of the lymph node cells, as can be seen in Table 1, according to a technique described else-

Table 1

					Radioactivity fixable on erythrocytes			
					Sheep erythrocytes		Rabbit own erythrocytes	
Exp. no.	Lymph node weight (gm.)	Type of culture	Duration of exp. (hr.)	TCA precipitate (c.p.m./ml.)	in c.p.m./ml.	Per cent of TCA precipitate	in c.p.m./ml.	Per cent of TCA precipitate
20	2·31	Lymph node cells	24	8,200	1,890	23	1,230	15
34	1·46	Lymph node cells	24	7,000	560	8	308	4·4
38	0·5	Lymph node cells	48	26,500	6,600	25	500	2
38	0·5	Lymph node fragments	48	61,100	8,000	13	550	0·9
45	0·39	Lymph node fragments	48	30,000	990	3·3	300	1

where[1]. This radioactivity increases with the duration of culture, is related to the cell metabolism (inhibited by dinitrophenol) and is related also to the level of immunization (titre of agglutination of sheep erythrocyte in the serum). Normal rabbit lymph node cells kept in the same conditions with radioactive amino-acids did not show any formation of such radioactive substances. 'Cold' controls showed very little radioactivity fixation on red cells. Dialysis of the culture fluid did not decrease the radioactivity fixable on rabbit erythrocytes taken from the donor of the lymph node cells or on sheep erythrocytes, but the radioactive material is precipitated by ammonium sulphate at 40 per cent saturation or by a goat specific anti-rabbit γ-globulin serum. Presence of large amounts of 'cold' anti-sheep erythrocyte serum inhibits the fixation of the radioactive material, presumably by competition. The positive results given by micro-agglutination and tracer techniques with rabbit erythrocytes taken from the donor of the lymph node cells lead us to believe that we have observed the synthesis of auto-antibodies in tissue culture.

However, in most experiments radioactivity fixable on normal rabbit erythrocytes is higher than radioactivity fixable on rabbit erythrocytes taken from the donor of the lymph node cells. This can be interpreted in two ways: either that there are less auto-antibodies than iso-antibodies formed (just as there are less iso-antibodies than hetero-antibodies), or that the autologous red cells are already coated by some sort of auto-antibodies synthesized *in vivo*, when they are collected.

Synthesis of antibodies *in vitro* indicates that the usual absence of circulating auto-antibodies in an animal may not be due to the specific disappearance of all cells competent for the synthesis of this kind of antibodies, such as is postulated in the 'forbidden clone' theory[3].

The possibility that such a synthesis of antibodies occurs also *in vivo* must be considered and is actually under experimental analysis.

These experiments lead us to believe that tissue culture offers an approach to the problem of formation of true auto-antibodies, the synthesis of which has been stimulated by an immunization with an immunogen structurally related to an antigen of the body.

RADIOBIOLOGY

Cross-linking of Deoxyribonucleic Acid to Protein following Ultra-Violet Irradiation of Different Cells

If deoxyribonucleic acid is exposed to ultra-violet light, especially to the 2537 Å. mercury arc line, a variety of changes occur. In very dilute solution the first physicochemical change is denaturation leading to a fall in viscosity without a change in molecular weight[1]. With higher doses, main-chain scission occurs and this is markedly enhanced by the presence of oxygen. There is chemical evidence for the formation of a dimer when thymine is irradiated in frozen aqueous solution[2] and for cross-linking between molecules when DNA is irradiated in dilute solution[3] or as a thin film[4]. The work reported here has shown that the changes produced in DNA when irradiated as a nucleoprotein inside cells are qualitatively and quantitatively different from those that are produced when pure DNA is treated.

Well-agitated suspensions in physiological saline (equilibrated with either nitrogen or oxygen) of *E. coli B*, murine lymphoma cells or salmon sperm heads were irradiated in physiological saline with a low-pressure 'Vycor' jacketed mercury arc in an apparatus[1] which enabled the dose of radiation absorbed by the DNA in the different cells to be computed, allowance being made for scattered light. To ensure that the alterations produced in the DNA were the direct consequence of the ultra-violet light (and not secondary effects of metabolism), the cells were irradiated at 0° C. and their DNA content extracted immediately afterwards. The test for the detection of cross-links between DNA helices was the formation of an insoluble gel network.

The cells were dispersed in 2 *M* sodium chloride and centrifuged for 1 hr. at 10,000 r.p.m. at 0° C. In the unirradiated cells all the DNA (as determined by the Burton method) was present in the supernatant. After irradiation, the cells appeared to disperse in 2 *M* sodium chloride, but some DNA was removed from solution on centrifugation in the case of sperm heads (Fig. 1) though no such effect was seen with *E. coli* or the lymphoma cells. This readily sedimentable DNA was seen to be in the form of a loose gel which we assume to be covalently cross-linked because it does not disperse in 8 *M* urea[5].

When the DNA was isolated from the cells by standard deproteinization procedures (Marmur's method[6] for *E. coli* and lymphoma cells and modified Dounce's method for sperm heads) the amount recovered decreased markedly on irradiation in all three systems (Fig. 2). We assume that the reason why some of the DNA from the irradiated cells is found in the insoluble protein fraction, instead of in the supernatant, is due to the fact that protein became covalently linked to the DNA and that this

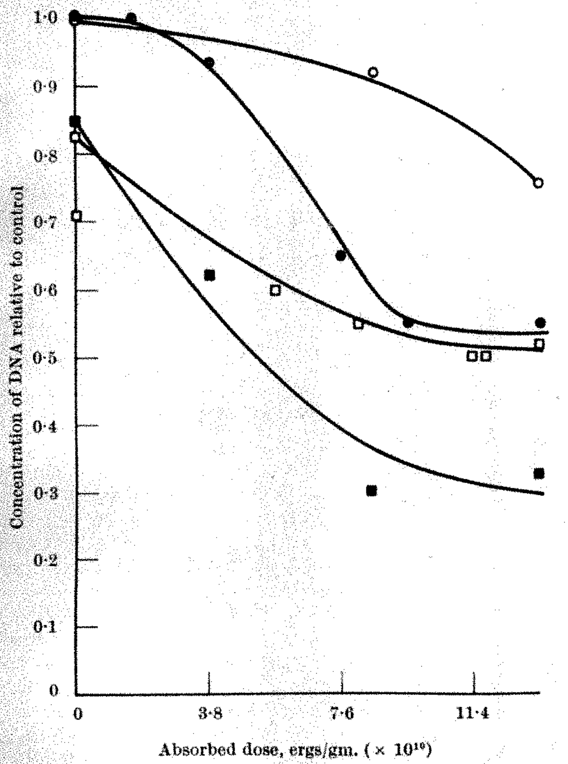

Fig. 1. Effect of ultra-violet light on the DNA in the nuclei of salmon sperm. Top lines, Fraction of DNA soluble in 2 *M* salt; the difference represents DNA in gel form due to DNA–DNA cross-links. ○, Irradiated under oxygen; ●, irradiated under nitrogen. Bottom lines, Fraction of DNA which can be isolated by the standard deproteinization procedure; the difference represents DNA in gel form + DNA linked to protein. ■, Irradiated under oxygen; □, irradiated under nitrogen

complex travels with the protein fraction during the separation procedure. This interpretation is supported by the fact that treatment of the cell suspensions with 0·5 per cent trypsin for 10 min. prior to deproteinization renders all the DNA extractable, presumably because the bound protein has been largely digested away. Trypsinization is without effect on the gel fraction ascribed to DNA–DNA cross-links in sperm heads.

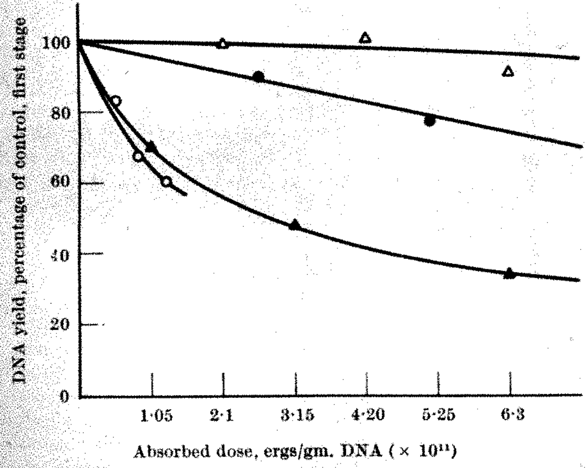

Fig. 2. Effect of ultra-violet light on the fraction of DNA that can be extracted from different cells by standard isolation procedures. ●, Murine lymphoma cells; ▲, *E. coli B*; △, *E. coli B* treated with trypsin before DNA extraction; ○, salmon sperm heads

Fig. 1 shows that while the presence of oxygen markedly reduces the extent of DNA–DNA cross-linking, it is initially without effect on the DNA-protein cross-links and at high radiation doses even enhances this reaction. The physical-chemical properties of the DNA which can be isolated are markedly affected by radiation and main-chain scission occurs much more readily when the DNA is irradiated within cells than in dilute solution. These results will be reported in detail elsewhere.

We suggest that the linking of protein to DNA may contribute significantly to the killing of cells by ultra-violet light, since this reaction is readily detectable by physico-chemical methods with amounts of radiation that are necessary for killing 99·9 per cent of the cells, and smaller doses are therefore likely to alter biologically significant amounts of DNA.

This investigation was supported by grants to the Chester Beatty Research Institute (Institute of Cancer Research: Royal Cancer Hospital) from the Medical Research Council, the British Empire Cancer Campaign, the Anna Fuller Fund, and the National Cancer Institute of the National Institutes of Health, U.S. Public Health Service.

Alterations in Deoxyribonucleic Acid from Regenerating Rat Liver after X-radiation *in vivo*

While it is thought that X-radiation *in vivo* does not produce any changes in the properties of deoxyribonucleic acid (DNA) which are associated with H bonding[1], alterations in its structure are suggested from differences in fractionation pattern on *ECTEOLA*[2,3] and from the diminished capacity of nuclei isolated after irradiation *in vivo* to act as templates for DNA synthesis[4]. The validity of the chromatographical evidence has been questioned for normal animals by Kondo and Osawa[5] and after irradiation[6,7], due to our ignorance of the means by which fractionation on *ECTEOLA* is attained and because of the possibility that the differences found between DNA from control and irradiated animals could be due to the action of DNases which are known to be activated in thymus after X-radiation. In view of these uncertainties, it was decided to extend our earlier observations on thymus DNA to regenerating rat liver. This tissue is advantageous since it is possible to irradiate at a known period in the mitotic cycle, and because in normal rat liver

activation of DNases post-irradiation is much less marked than in thymus[8]. DNA was isolated by Kirby's method[9], which would reduce to a minimum DNase action during the isolation.

Male animals (200 ± 20 gm.) of the laboratory stock of Wistar rats were used. 24 hr. after hepatectomy, that is, in the first peak of DNA synthesis, they were given 2,000 r. total-body irradiation (77 r./min.). Immediately following exposure they received 100 μc. phosphorus-32/100 gm. body-weight and were killed 30 min. later. Control animals were treated similarly except for the absence of irradiation. DNA from control and irradiated rats was prepared simultaneously. 24 animals were used per group, and 20 or 30 mgm. material was applied to *ECTEOLA* columns[10] and the fractionation carried out in parallel with a common reservoir and mixing flasks. Preliminary experiments established that identical samples of DNA on the two columns showed less than 3 per cent difference in ultra-violet and phosphorus-32 elution patterns in peaks 2 and 3 (Table 1) and less than 6 per cent difference in peak 4. Peak 1, which represented a minor component, was thought to contain denatured material and was more variable (13 per cent).

X-radiation (Table 1) produced no change in the ultra-violet absorption characteristics of the unfractionated material, although incorporation of phosphorus-32 was reduced to 40–50 per cent of the control-level. The material eluted by 2 *M* sodium chloride/0·1 *M* ammonia (peak 2) was increased after exposure at the expense of peaks 3 and 4. In both experiments the inhibition of the uptake of phosphorus-32 was most marked in peak 3. Measurement of the melting point temperatures[12] of peak 2 and the base ratios of peaks 2 and 3 failed to show any differences in these respects between the control and irradiated fractions.

The difference in behaviour of the different peaks after exposure and the lack of change in H bonding suggest that the altered fractionation pattern is not due to DNase action. Although the effects are small this is to be expected since the DNA was isolated by procedures which might eliminate grossly damaged molecules. The changes observed provide additional evidence for alterations in DNA structure after X-radiation *in vivo*.

We thank Dr. G. E. Harrison of the Medical Research Council Radiobiological Research Unit, Harwell, for providing some of the facilities for these experiments, and the Medical Research Council for a grant to one of us (R. F.). Financial assistance for this work has been provided by the Department of Scientific and Industrial Research and the International Atomic Energy Agency.

Ray Cataract in the Lens of the Eye caused by Wounding after X-Irradiation

SOME years ago I found that, on being turned about in the anterio-posterior direction, the inverted rounded lens of an amphibian larva underwent a reverse turn and in a few days came to occupy its previous position[1,2].

A single roentgen-ray action (500 r.) on a tadpole reduces the electric potential in the retina and the lens and prevents a reverse turning of the inverted lens, and a 1,500-r. dose results in destroying the lens. This unexpected result may be explained only by an intra-ocular surgical interference made after a relatively strong ionizing irradiation, because eyes irradiated with the same dose but left unoperated, or unirradiated but operated eyes, remained quite normal without showing any phenomenon of 'surgical after-action'[3].

I have now carried out similar experiments on adult frogs (*Rana temporaria*) and on white stock mice. The heads of these animals were irradiated in a diagnostic roentgen apparatus (*RUD* 100 kV./20 m.amp.) and after 2 days the X-rayed lenses were cut to a depth of half their diameter.

Up to the present time such operations have been made on 49 frogs and 30 mice. The right eye of the

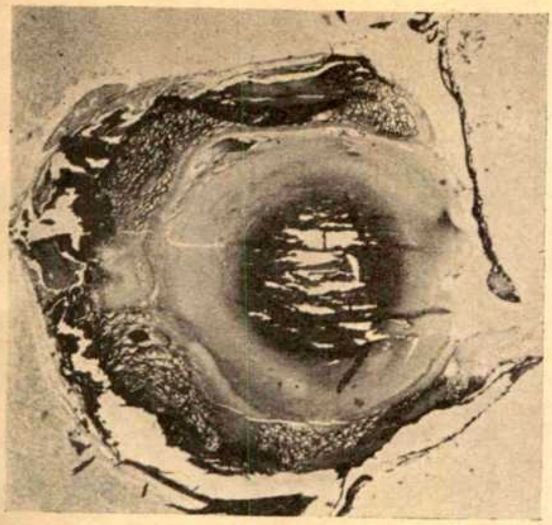

Fig. 1. Lens of a frog irradiated with 1,000 r. showing traces of incision 3–14 days after operation. A homogenized fibrous mass and numerous spheric cells can be seen. (× 20)

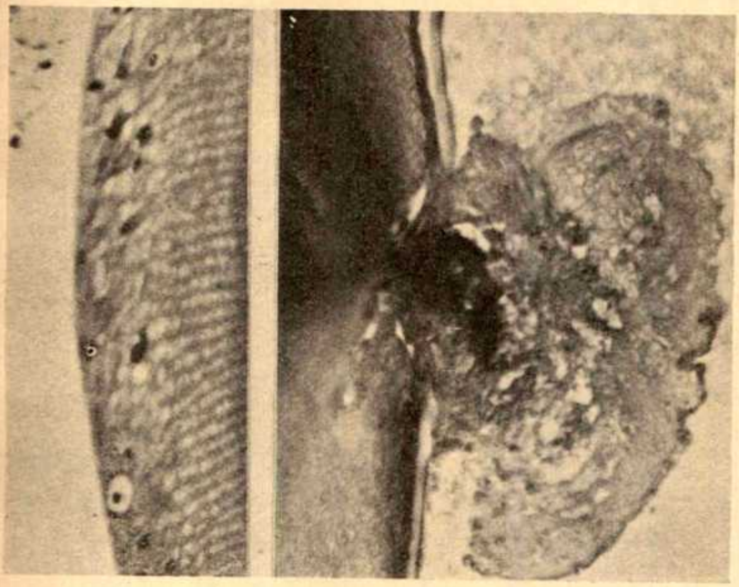

Fig. 2. Beginning of cataract-changes in the lens of a mouse irradiated with 800 r. on the second day after operation. The formation of epithelium on the posterior (left) and traces of incision on the anterior (right) poles. (× 230)

irradiated animal was operated on, while the left one served as control. Moreover, some control experiments took the form of incision of the lens of unirradiated animals.

Twenty frogs received 1,000 r., 18–2,000 r. and 11–4,000 r.

Even on the third or fourth day following the operation, either a slight or a most pronounced, but always a more or less steady, opacity of lens became evident. 8–9 days after operation 90 per cent of lenses were very opaque, and after about a fortnight the milk-white contents of a rather shrivelled lens began to emerge in the form of a loose mass into the aqueous humour of the anterior chamber of the eye. Similar changes took place after an irradiation with 2,000 r.; but in this case a very strong total opacity of lens appeared as a rule even on the first–second day after operation, reaching its limit in 7–9 days. Finally, after a 4,000-r. irradiation almost the entire lens became densely opaque on the day following treatment.

Nineteen mice received 350 r. and 11–800 r. There were ten control experiments.

Irradiation with 350 r. caused a change in the lens 10 days after operation in living mice. In this case, therefore, unlike frogs, the lens became opaque later and opacification was rather unsteady. Approximately by the eighteenth day it reached its greatest density. Irradiation with 800 r. resulted in accelerating the process, and as early as on the fifth day there began to form a rather dense cataract which reached its highest development by the eighth–tenth day.

It is worth noting that the left unoperated eyes of test frogs and mice remained clinically quite normal during the whole experiment, that is, for 20 days.

In the control experiments, the unirradiated lenses became slightly opaque in the region of incision; but this soon disappeared. In individual cases only such a local opacity, increasing somewhat in dimensions, remained until the end of the experiment. But even then no complete traumatic cataract of the lens appeared.

Histological examination of my material at different dates after operation has shown that opacity occurs very rapidly after the first irradiation, and there is a connexion between wounding and the formation of cataract. It seems that a ray cataract is caused by the act of wounding by incision.

The development of the cataract proceeded so violently, in frogs particularly, that it was impossible to follow the usual stages of its formation. In frogs the lens began to swell at once, which did not allow it to become separated from that of a ripe and often even an over-ripe cataract. The most characteristic stages in changes in the lens of frogs and mice are shown in Figs. 1 and 2.

The experiments render it necessary to take into consideration a possible risk during an intra-ocular operation on a patient, if such operation is preceded by a relatively strong ionizing irradiation. Furthermore, the question arises as to the terms of an intra-ocular surgical intervention in connexion with a probable increase and disappearance of a 'surgical after-action'. Moreover, it would be pertinent to investigate the probable importance of an accumulation of small, but multiple, doses of ionizing radiation for the manifestation of a negative effect detected in my experiments. Finally, it seems that the rapidly reacting eyes described here could be successfully used in more extensive work on chemical protection of the eye from the harmful action of ionizing radiations.

A Pool Size Problem associated with the Use of Tritiated Thymidine

HELL *et al.*[1] have directed the attention of research workers to the fact that errors may result from the use of high specific activity radioactive compounds when the intracellular concentration of the corresponding metabolites is very low. In particular they mentioned tritiated thymidine and showed that the apparent effects of irradiation on the incorporation of this compound by Ehrlich ascites cells depended on whether tritiated thymidine of high or low specific activity was used. They ascribed this effect to differences in pool size in the irradiated cells.

In a set of experiments designed to investigate variations in the amount of deoxyribonucleic acid (DNA) per HeLa cell during the course of infection with herpes virus, which have been described in detail elsewhere[2], we have obtained similar results which can be attributed to a marked variation in size of nucleotide pool during the course of the experiments.

Four of these experiments are relevant: (1) Measurements were made of the total amount of DNA in single HeLa cells in Feulgen-stained cultures fixed at various times after infection with herpes virus. These measurements were made using a microspectrophotometer and the two wave-length method[3-5]. Measurements on about 30 cells per culture gave an estimate, in arbitrary units, of the mean amount of DNA per cell and this was found to vary with time (Fig. 1). These results confirmed those obtained by Newton and Stoker[6], who measured the increase in DNA content of herpes-infected HeLa cells by a chemical method.

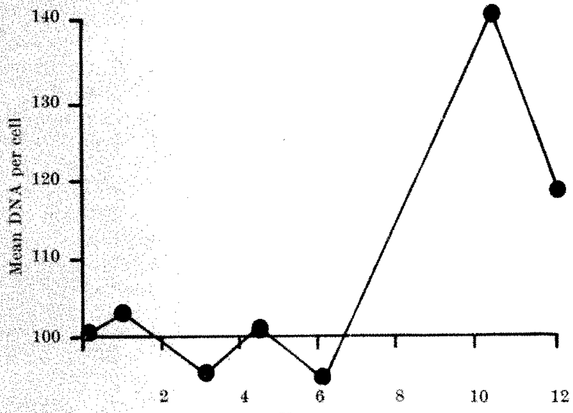

Fig. 1. Ratio of mean DNA per cell in the infected cells to that in controls averaged over three experiments

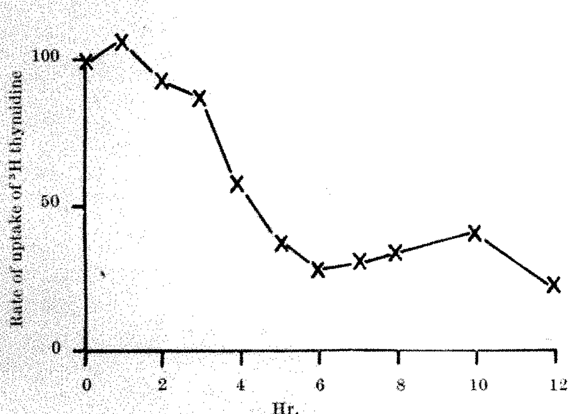

Fig. 2. Average of two experiments in which the rate of uptake of tritiated thymidine by infected cells in grains/nucleus/0·5 min. is expressed as a percentage of that in uninfected control cells

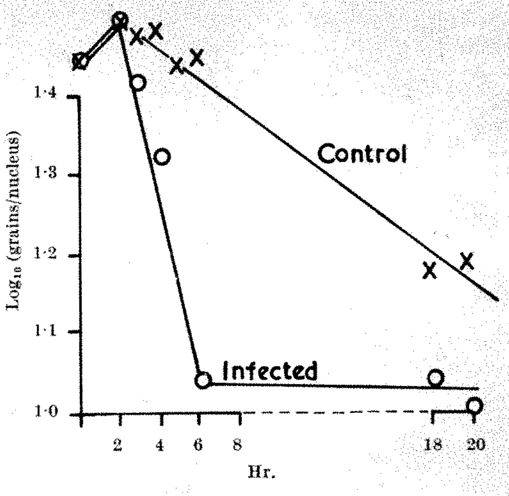

Fig. 3. Curve showing the loss of label from cells following infection. The cells had been incubated with 0·19 c./m.mole tritiated thymidine for 24 hr. prior to infection

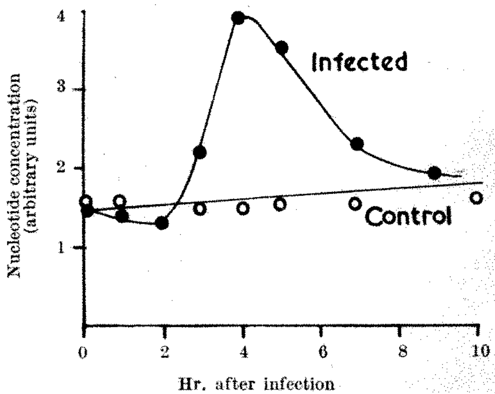

Fig. 4. Nucleotide content of HeLa cells infected with herpes virus

(2) The rate of uptake of tritiated thymidine into HeLa cells at various times after infection was measured by placing the cultures in tritiated thymidine for 0·5 hr. at varying times after infection, fixing immediately, making autoradiographs, and measuring the mean number of developed grains over the nuclei in the autoradiographs. This mean grain count reflects the rate of uptake of tritiated thymidine and might be thought to give an estimate of the rate of DNA synthesis. The results obtained are shown in Fig. 2.

(3) HeLa cells were labelled with tritiated thymidine before infection. Immediately before infection the tritiated thymidine was replaced by an equal concentration of unlabelled thymidine and the amount of label remaining in the cells was measured autoradiographically at different times after infection. The amount of label in infected cells fell rapidly to a low value and then remained constant (Fig. 3).

The second experiment indicates only a continuously decreasing rate of uptake of tritiated thymidine with time, whereas the microspectrophotometric results show that DNA is being rapidly synthesized between 6 and 10 hr. after infection. The explanation which we favour is that during the period

2–6 hr. after infection, cell nucleic acid is being rapidly broken down by the virus to give a large intracellular pool of nucleotides, polynucleotides and nucleosides. The results of the third experiment are consistent with these ideas.

(4) The fourth experiment was designed to investigate this point. The amount of acid soluble nucleotide extractable from the cells was estimated at varying times after infection (Fig. 4). These measurements indicate that there is indeed an increase in the size of pool in infected cells.

In consequence, even though DNA synthesis (probably induced by the virus) is rapid during the 6–10-hr. period, the tritiated thymidine is now only a small fraction of the nucleotide pool. Hence the rate of incorporation of label decreases continuously and in no way reflects the rate of DNA synthesis. This seems to be an extreme example of phenomena in which the effects of size of pool must be taken into account and in this case the difficulty would arise even with low specific activity precursor.

BIOLOGY

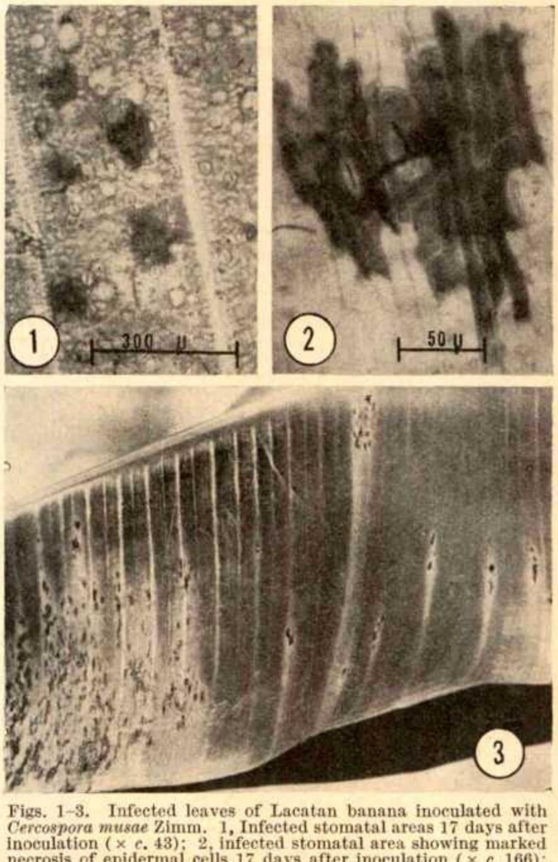
Establishment of Sigatoka Disease of Bananas in the Greenhouse

ALTHOUGH Sigatoka disease of banana has been known for a half-century and is a serious problem in most banana-growing areas, many fundamental aspects of the disease and of the life-history of the causal organism, *Mycosphaerella musicola* Leach (= *Cercospora musae* Zimm.), remain poorly understood. Present knowledge has been derived largely from field observation of the disease and pathogen and from field inoculation studies[1–4]. Successful greenhouse inoculations have not been reported, although many investigators have been interested in studying the disease under controlled conditions. In the field, Sigatoka outbreaks are coincident with periods of wet, humid weather[1,2], and laboratory investigations have shown that conidia of *C. musae* must be immersed in a water film for germination to occur[2]. Failure to obtain adequate humidity and/or moisture films on the leaf surface may account for the lack of reported greenhouse studies of this disease.

This communication is a preliminary report on greenhouse inoculation studies with *C. musae*, and describes a method by which successful infections were obtained.

A sporulating culture of *C. musae*[5], originally obtained from Dr. L. Calpouzos, U.S. Department of Agriculture Experimental Station, Mayaguez, Puerto Rico, and maintained in our laboratory for three or more years, was used for this work. Inoculum was obtained from week-old plate cultures grown on Difco mycological agar. Plates were inoculated by spreading a heavy conidial suspension evenly over the agar surface, and were incubated at 25° C. Conidia were collected by flooding the plates with sterile distilled water and gently massaging the culture surface with a rubber 'policeman'. Inoculations were made on susceptible varieties by spraying conidia on to the lower surface of the youngest unfurled leaf with an atomizer and compressed air. Microscopic observations of spore germination and stomatal penetration were made periodically by examining sections of inoculated leaves stained with aqueous crystal violet.

In preliminary experiments, inoculated leaves were enclosed individually in plastic bags immediately after inoculation to maintain a high relative humidity near the leaf surface. Uncovered inoculated leaves were maintained as controls. On covered leaves, germination began with 24 hr. of inoculation, and 80–95 per cent germination was attained within 48 hr. No germination occurred on uncovered leaves, even after several weeks. Stomatal penetration was generally evident on covered leaves 4–6 days after



Figs. 1–3. Infected leaves of Lacatan banana inoculated with *Cercospora musae* Zimm. 1, Infected stomatal areas 17 days after inoculation (× *c*. 43); 2, infected stomatal area showing marked necrosis of epidermal cells 17 days after inoculation (× *c*. 166); 3, streak and spot symptoms 7 weeks after inoculation

inoculation, and nine to sixteen days after inoculation infected areas were barely visible macroscopically as small necrotic spots (Figs. 1, 2). Symptom development ceased at approximately this stage, even on leaves kept continuously covered for as long as two months. Adjustment of environmental conditions by daily removal and replacement of bags was also without effect in inducing streak and spot development. The fungus was recovered from infected leaves 12 weeks after inoculation, however, indicating that failure to obtain advanced symptoms was not due to death of the fungus.

Results of these experiments suggested that suitable environmental conditions for pathogenesis had not been achieved by bagging the leaves, or that an avirulent strain of the fungus had been used. Subsequent experiments were attempted, therefore, in which inoculated plants were placed in a plastic tent equipped with an overhead misting system controlled by a humidistat. With this system, relative humidity was maintained near 100 per cent, and the plants were subjected to a simulated mist rain. Plants were inoculated as in the previous experiments with two strains of *C. musae*: (1) the strain used in the preliminary experiments; (2) an isolate newly recovered from infected leaf material in Puerto Rico and sent to us by Dr. L. Calpouzos. Inoculated leaves covered with plastic bags, or left uncovered in the open greenhouse, were also included in the experiment. Following inoculation, plants in the plastic tent were maintained under constant high humidity for a period of nine days to induce spore germination. For the next three weeks, these plants were subjected to periods of alternate wetting and drying by daily opening of the tent for 6-hr. periods. It has been suggested that alternate wetting and drying may be a factor favouring development of this disease[6]. Four weeks after inoculation, the plants were removed from the tent to normal greenhouse conditions. At this time, small necrotic areas, similar to those observed on bagged leaves in the preliminary experiments, were the only visible evidence of infection.

Seven weeks after inoculation, typical streak and spot symptoms began to develop on those leaves inoculated with the newly isolated strain of *C. musae*, but only on those plants which had been held in the plastic tent (Fig. 3). Streaks and spots failed to develop on leaves inoculated with the strain used in the preliminary studies, indicating that this strain was probably avirulent. Neither strain induced symptoms beyond the small necrotic spots on leaves enclosed individually in plastic bags even after eleven weeks, although a few spots did develop on a single leaf inoculated with the virulent strain after thirteen weeks. Conidia failed to germinate on uncovered leaves. The fungus was readily recovered from infected leaves by placing leaf spots in moist chambers to induce sporulation, and transferring conidia to agar slants.

Work is now in progress to determine more precisely the conditions necessary for stomatal penetration and development of disease. Greenhouse investigations of this disease may be applicable to a variety of unsolved problems, including examination of the use of fungicides and oils in disease control, natural resistance mechanisms, selection of resistant varieties from hybrid progeny, determination of the factors influencing development of the ascigerous stage, and the role of the ascospore in the establishment of new infections.

We thank Dr. L. Calpouzos for providing cultures and for his suggestions.

Control of Penicillium Decay of Citrus Fruits with 2-Aminobutane

IN evaluating a number of simple aliphatic amines as volatile post-harvest fungicides for use on citrus fruits, we found that 2-aminobutane (*sec*-butylamine) was remarkably effective in reducing decay incited by *Penicillium digitatum* Sacc.[1]. Subsequent experiments[2] revealed that effectiveness of this amine is mainly due to the fungistatic action of butylammonium salt residues persisting on the fruit after fumigation. *In vitro* tests showed that germination of *Penicillium* spores was almost completely inhibited by 10^{-3} *M* 2-aminobutane, and, furthermore, that this inhibition could be completely reversed by washing the spores in neutral phosphate buffer, followed by transfer of the spores to amine-free medium. A number of other lower ($< C_6$) primary monoamines were tested by this procedure and found to be ineffective in preventing spore germination. These results prompted an evaluation of 2-aminobutane in fruit washes and wax emulsions for control of *Penicillium* decay of citrus fruits.

Ice-cold aqueous solutions of 2-aminobutane were neutralized with an equivalent quantity of dilute hydrochloric acid and the resulting salt solution diluted with either water or wax emulsion to the desired amine concentration. For evaluation as a wash treatment, the diluted amine solution was adjusted to *p*H 10·5 (*pKa* 2-aminobutane = 10·56) or to *p*H 6·5. Since the paraffin-carnuba wax used was emulsified with triethanolamine oleate, the *p*H of the concentrated amine hydrochloride solution was adjusted to that of the emulsion, *p*H 8, before the two were combined. Valencia oranges or Eureka lemons were inoculated by scratching the fruit with a rotary saw blade[3] passing through a suspension of *Penicillium* spores containing 5×10^6 spores per c.c. The inoculated fruit was then incubated at 24° C. for 16 hr. before application of the amine treatments. The inoculated oranges were submerged in the amine solution for 4 min. and either dried directly or rinsed in a tank of water for 5 sec. and then dried. Three replicate lots of 30 oranges each were treated with each of the solutions listed in Table 1 and packed in 6 × 9 × 11 in. fibreboard cartons. Lemons were inoculated in the manner described for oranges, immersed in the appropriate wax formulation (Table 2) for 5 sec. and, after the excess wax drained from the fruit, were placed in open wood boxes. All fruit were stored at 20° C. to permit development of decay. Sodium *o*-phenylphenate, an extensively used citrus decay control agent, was included for comparison in both wash and wax tests.

Table 1. CONTROL OF *Penicillium digitatum* ON ORANGES BY AQUEOUS SOLUTIONS OF 2-AMINOBUTANE

	Treating solution	*p*H	Water rinse	Per cent decay in	
				7 days	14 days
A	Water only—control	10·5	yes	98	100
B	0·5 per cent 2-aminobutane	10·5	yes	1	22
C	0·5 per cent 2-aminobutane	10·5	no	0	2
D	0·5 per cent 2-aminobutane	6·5	yes	12	49
E	0·5 per cent 2-aminobutane	6·5	no	1	14
F	0·5 per cent sodium *o*-phenylphenate	12·0	yes	1	14

Table 2. COMPARISON OF WATER WAX EMULSIONS CONTAINING 2-AMINOBUTANE AND SODIUM *o*-PHENYLPHENATE IN RETARDING *Penicillium digitatum* ON LEMONS

Fruit treatment	Per cent decay in 14 days
Wax emulsion only	58
Wax emulsion with 1 per cent 2-aminobutane	7
Wax emulsion with 2 per cent 2-aminobutane	0
Wax emulsion with 1 per cent sodium *o*-phenylphenate	2

Table 1 shows that washing oranges in aqueous 0·5 per cent 2-aminobutane solutions greatly retarded the development of *Penicillium* decay and, at *p*H 10·5, the fungistatic activity of the rinsed amine treatment was only slightly less than that of sodium *o*-phenylphenate. The solutions at *p*H 10·5, which contained appreciable quantities of non-ionized amine, were more effective than those adjusted to *p*H 6·5, and efficiency at both *p*H values was enhanced by allowing 2-aminobutane residues to remain on the fruit. Although non-ionized 2-aminobutane undoubtedly penetrates lypophilic barriers of the fruit and fungus more readily than the butylammonium ion, persistence of amine salts on the fruit can satisfactorily account for the effectiveness of the wash treatment (cf. treatments *B*, *C*, and *E*, Table 1). The greater penetrating power of the non-ionized amine probably facilitates movement of the amine to the potential infection site. In other experiments, treatment of fruit with 1 per cent 2-aminobutane solution at any *p*H, followed by rinsing, has virtually eliminated decay.

Table 2 shows that a water wax emulsion containing 2-aminobutane provides decay control equivalent to one containing sodium *o*-phenylphenate. Although the triethanolamine oleate emulsifier necessitated treatment at *p*H 8 in this instance, we have obtained excellent decay control at *p*H 6 with 2-aminobutane water waxes containing non-ionic emulsifiers.

A number of other simple monoamines have been tested as citrus fruit washes at the molar equivalent of 0·5 per cent 2-aminobutane and at their respective *pKa* values. All other amines evaluated were completely ineffective. In screening trials carried out in Florida[4-6], a number of amines have been evaluated in wash solutions for control of citrus fruit decay. With the exception of several complex quaternary ammonium compounds, the amines tested were not considered effective for this purpose. Furthermore, certain amines were reported[5,6] to cause fruit rind injury. In our tests with 2-aminobutane we have never observed fruit injury attributable to the amine treatment, even when residues from 2 per cent 2-aminobutane solutions were permitted to dry on the fruit.

Unlike many commonly used citrus fruit-wash chemicals, such as sodium tetraborate and sodium carbonate, 2-aminobutane is an efficient decay-control agent when applied at room temperatures (about 25° C.). Sodium *o*-phenylphenate is widely used as a low-temperature fruit-wash; but the potential hazard of fruit injury from this chemical is well known[7]. Furthermore, there is considerable evidence[8] that continuous use of sodium *o*-phenylphenate washes in lemon packing houses may lead to the build-up of *P. digitatum* strains which possess resistance not only to *o*-phenylphenol, but also to biphenyl, a fungistat commonly used in citrus shipments. We have tested 2-aminobutane against both biphenyl-sensitive and biphenyl-resistant strains of *P. digitatum* and found both groups equally inhibited at concentration of 10^{-3} *M* amine. The dissimilarities in chemical structure, and probably mechanism of inhibition, makes it highly unlikely that *P. digitatum* could develop cross-resistance to biphenyl and 2-aminobutane.

From results obtained in the small-scale tests reported here, 2-aminobutane appears to offer considerable advantage over existing commercial fruit-wash and wax fungicides. The combined virtues of effective control of *P. digitatum* at room temperatures and over a wide *p*H-range, with negligible hazard of fruit injury, give 2-aminobutane considerable potential as a fruit decay control agent for use in California. However, in other citrus producing areas where major decay problems are due to organisms other than *Penicillium*, the utility of this fungistat may be limited.

Preliminary tests have shown that 0·5 per cent 2-aminobutane solutions effectively control *Penicillium expansum* Thom on apples, even when the solution temperature is held at 2° C.

An analytical method has been developed for 2-aminobutane residues on treated fruit, and commercial citrus fruit treatment trials are in progress.

We thank Mr. R. L. Slusher, of this laboratory, for assistance in conducting the fruit decay control tests and Mr. D. Cothron, Brogdex Co., for assistance in the development of commercial water wax formulations containing 2-aminobutane. Generous samples of 2-aminobutane were supplied by the Pennsalt Chemicals Corp.

A Peculiar Ericalean Pollen Grain

IN the genus *Styphelia* Sm., the Epacridaceae include a pollen form previously not known in this or related families. I have examined the patterns of ektexine ornamentation in pollen from all genera of the Epacridaceae. The grains are mostly similar to those of allied families, in that they are either smooth or have an ornamentation which is inconspicuous except under oil immersion. Those of *Styphelia*, however, are strikingly different. Of the eleven species recognized by Bentham[1], I have been able to investigate ten, and in these the grains are always provided with warts (Fig. 1), the largest of

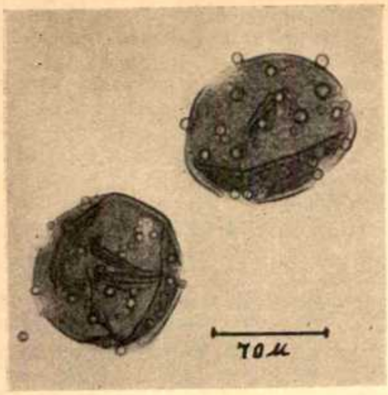

Fig. 1. Acetolysed pollen grains of *Styphelia triflora* Andr.

which are usually conspicuous at quite low magnifications and may be more than 10μ in diameter. As can be seen in the photograph, the warts are rather easily detached, and at first sight they could be mistaken for oil droplets. The grains of *S. tenuiflora* and *S. melaleucoides* have smaller warts than do the other species, but even here they are easily distinguished from those of related groups. Similar forms occur in distant families (for example, Nymphaeaceae), but the pollen of *Styphelia* appears to be without parallel in the Ericales.

Styphelia is now confined to Australia, with the disjunct distribution of a relict genus. Its near relatives are almost exclusively Australasian or Malaysian, but from the occurrence of *Leucopogon* fruits in the London clay[2], it is evident that the group must formerly have had a far wider range. Therefore it is possible that *Styphelia* pollen has been observed in fossil samples, and that palynologists failed to identify it.

Several taxonomists, including a few modern ones, have suggested that a number of allied genera should be regarded as sections of *Styphelia*. Australian botanists, however, who are more intimately concerned with these plants than anyone else, would not welcome the addition of several hundred synonyms to a confused nomenclature. Furthermore, the evidence from pollen structure indicates that the amalgamation might be as taxonomically unsound as it is unpractical.

I thank Dr. J. W. Franks, of the Manchester Museum, for his advice; the Keeper of the Herbarium at the Royal Botanic Gardens, Kew, for the loan of specimens; and the Department of Scientific and Industrial Research, for financial support.

Role of the Corpus Luteum in Marsupial Reproduction

IN marsupials the histological changes which occur in the ovaries and uteri of unmated females after ovulation appear to be very similar both in degree and duration to those occurring during pregnancy[1]. The gestation period is shorter than the length of an œstrous cycle in all the polyœstrous marsupial species so far investigated, and some workers consider that this can be accounted for by a similarity between the duration of the functional life of the corpus luteum in pregnant and non-pregnant females, and of the gestation period[2]. Thus, Sharman[3] and Amoroso[4] postulate that the hormonal control both of the œstrous cycle and of pregnancy may be identical and that the simple yolk-sac placenta characteristic of most marsupials probably has little or no endocrine function comparable to that of the true allantoic placenta of eutherian mammals. One of the implications of this hypothesis is that pregnancy in marsupials would be largely maintained by the progesterone produced by the corpus luteum. However, a few marsupials, including the long-nosed bandicoot *Perameles nasuta* Geoffroy, have true allantoic placentæ[5,6] and therefore the reproductive physiology of such species is of considerable interest.

Observations were made on 57 *P. nasuta* females. Vaginal smears were taken from 31 animals. The interval separating successive peaks of vaginal cornification in 8 œstrous cycles averaged 26 days (range 17–34 days). Ovulation occurred irrespective of the presence of males. Examination of the reproductive tracts of 21 females on capture indicated that both ovaries were functional. The total number of ova shed in one cycle was most frequently either two or three. In all but two of the females the number of corpora lutea corresponded exactly with either the number of uterine embryos or of pouch-young. In the two exceptions the number of pouch-young was less than the number of corpora lutea. The gestation period (the interval separating copulation and parturition) was greater than 8 days in one instance, and 12 ± 1 days in another.

In the examination of reproductive tracts, uteri from four pregnant females were included (the blood vascular system of the trophoblast was either in the process of development or recently developed). Seventeen females were carrying pouch-young and represented a graded series during pouch life; seven were killed between parturition and 11 days of pouch life. There was no macroscopic evidence of degenerative changes in the corpora lutea or of the imminence of œstrus until the litter was more than 40 days old (the ages of pouch-young were estimated from unpublished growth-curves of Dr. A. G. Lyne). Vaginal smears taken during pregnancy and the first 40 days of lactation likewise gave no evidence of œstrus.

The fully formed corpora lutea of pregnancy had a diameter of about 2·8 mm. During the first week of pouch life the diameter decreased to about 2·2 mm. Microscopic examination of the ovaries showed that the large spherical nuclei of the luteal cells also decreased in diameter at this time. No further reduction occurred in the size of the corpora lutea until the litter was more than 40 days old. Rapid regression then followed, the luteal cells degenerating and being replaced by connective tissue which also eventually disappeared.

It appears that the corpora lutea of pregnancy do not normally involute until the offspring have suckled for about 45 days (approximately two-thirds of the total period of lactation). The degeneration of the corpora lutea at this stage permits females to return to heat and become pregnant before the completion of suckling (6 records). Parturition occurs after the suckling litter was weaned. If suckling is terminated by removal of the litter from the pouch the corpora lutea disappear within 10–14 days. Five females carrying litters between 27 and 40 days of age returned to œstrus 8–9 days after removal of the litter. Twelve other females carrying litters younger than 27 days or older than 40 days failed to return to œstrus after the removal of their litters. Œstrus was taken as the degree of vaginal cornification or uterine proliferation and vascularity that had previously been found to be associated with mating and ovulation.

The persistence of the corpus luteum of pregnancy as the corpus luteum of lactation has also been reported in another Australian marsupial, *Dasyurus quoll* (= *D. viverrinus*). Sandes[7] found that the corpus luteum in this species formed within 3 days after ovulation and persisted virtually unchanged throughout pregnancy and the greater part of lactation, ultimately disappearing when the litter was capable of leading an independent life. Although the allantois in *D. quoll* does not enter into the formation of the placenta in the same way as it does in *P. nasuta*, it nevertheless shows a greater development than that found in the majority of marsupial species that have only a yolk-sac placenta.

P. nasuta is similar to all other polyœstrous marsupials investigated in that the gestation period is less than the length of an œstrous cycle. However, the occurrence of parturition in the presence of an apparently functional corpus luteum raises some doubts as to the validity of the hypothesis that the hormonal control of pregnancy is identical with that of the normal œstrous cycle. This hypothesis rests largely on the occurrence of parturition after the degeneration of the corpora lutea of pregnancy in *Setonix*, *Trichosurus* and *Didelphys*[2].

In *Setonix brachyurus* the corpus luteum begins to degenerate quite some time (about 7 days) prior to parturition[1], so that it appears parturition is not as closely related to the functional life of the corpus luteum, at least in *Setonix*, *Perameles* and *Dasyurus*, as was originally thought. It would be premature at this juncture to speculate whether or not the marsupial placenta produces hormones.

Effect of Cortisone on the Developing Mouse Fœtus

THE discovery that cortisone acts as a teratogenic agent was made first in Fraser's laboratory at McGill[1]. In the intervening years, Fraser and his students have published a number of papers reporting investigations which have extended the original findings (for a general review see Fraser[2]). Within the framework of these experiments it appears that the effect of the cortisone on the mouse fœtus is specific. The only gross defect which has been reported so far is cleft palate (although some minor morphological effects have been recorded by Kalter[3]). The purpose of this communication is to report a new effect of cortisone on the developing mouse fœtus.

During the course of an investigation[4] in which cortisone and fasting[5] were used as teratogenic agents in various inbred mouse strains, areas of yellow-brown pigment were noted in the birth membranes of the fœtuses of a *C57BL/6* Jax strain female autopsied on the nineteenth day of pregnancy. This female had received cortisone injections (2·5 mgm. of cortisone acetate intramuscularly in the flank) on the twelfth, thirteenth and fourteenth day of pregnancy. All fœtuses removed from uteri during the remainder of the experiment were examined for this feature. The results of these observations are recorded in Table 1. There was an inter- and intra-litter variability in the amount of pigment in the birth membranes and since a quantitative scoring method was not feasible, Table 1 is based simply on the presence or absence of pigment.

Table 1. FREQUENCY OF OCCURRENCE OF PIGMENTED AREAS ON FOETAL MEMBRANES AND ITS RELATION TO CLEFT PALATE IN THE *C57BL/6* JAX FOETUSES

			Relation of cleft palate and occurrence of pigment areas in birth membranes					
			Fœtuses with cleft palate			Fœtuses without cleft palate		
Treatment	No. of litters	No. of fœtuses	No.	No. with pigment	Per cent with pigment	No.	No. with pigment	Per cent with pigment
Controls	10	61	1	1	100	60	2	3
Cortisone	28	154	49	47	96	105	97	92
Fast 9th day + cortisone	10	43	21	21	100	22	20	91
Fast*	19	99	0	0	0	99	2†	2

* Combining data from groups fasted on 8th or 9th day

† Both animals with exencephaly and bilateral eye defects.

The most significant feature of the observations is the high frequency of pigment patches in the fœtal membranes of fœtuses the dams of which had received cortisone. However, the presence of the pigment appears to be independent of the occurrence of cleft palate, since 96 per cent of the fœtuses with cleft palate and 92 per cent of the fœtuses without cleft palate in the cortisone-treated group had pigmented membranes. It will be noted that five animals with pigmented membranes (three in the control series and two in the fasted group) were born to dams which had not received cortisone. The three animals in the control series were all much lighter than their litter mates when they were removed from the uterus. Two of these, including the one with cleft palate, occurred in one litter. The two animals in the fasting-treatment series were the only fœtuses in a litter of a female who was fasted during the eighth day of pregnancy. Both fœtuses had exencephaly and bilateral eye defects, and were much lighter in weight than the average new-born of this strain.

In addition to these observations on the *C57BL/6* Jax strain, pigmented birth membranes were noted in the fœtuses of some strain *LG/Rr* females which had received cortisone. The pigment was not easy to detect in this strain, and may well have been overlooked during some of the earlier autopsies. As a result, the numbers are so few and unreliable that they are not included in this communication. Pigmented membranes were also observed in a fœtus with exencephaly but a normal plate the dam (*LG/Rr* strain) of which had been subjected to the fasting plus cortisone treatment.

To my knowledge, there have been two previous instances in which similar pigmented fœtal membranes have been observed after the administration of teratogenic agents. In Runner's laboratory at the R. B. Jackson Memorial Laboratory, similar patches of yellowish-brown pigment were observed in the birth membranes of fœtuses the dams of which (prepuberal) had received insulin injections (Runner, M. N., personal communication). Haskins[6], using nitrogen mustard as a teratogenic agent in the rat, describes areas of "brown, necrotic tissue . . . around the periphery of the placentæ of the more grossly affected fœtuses".

On the basis of the present observations, it would seem reasonable to conclude that the abnormal features of placental development, manifested by the pigment areas, represent expressions of the cortisone treatment which are not related causally to the production of cleft palate. Confirmation of this conclusion must await the results of further studies. However, the findings presented in this communication do direct attention to the fact that the placenta is an integral part of the maternal-fœtal complex and, as such, cannot be neglected in the study of mammalian development.

This work was carried out while I was holding a fellowship from the Roscoe B. Jackson Memorial Laboratory.

Auto-inhibition of Reproduction in *Cura formanii* (Turbellaria)

EVIDENCE for the widespread phenomenon of organismic interaction through chemicals released into the environment is summarized by Lucas[1]. One type of such interaction occurs between organisms of the same species. In tadpoles[2], for example, the effect of such substances is to inhibit the growth of individuals exposed to sufficient concentrations. This mechanism tends to limit the number of individuals of a given species within an area and thereby also limits depletion of environmental resources.

The eggs of the triclad turbellarian, *Cura* (= *Curtesia*) *formanii*, are normally fertilized by sperm from the same animal[3]. Copulation has never been observed, and individuals isolated from birth produce cocoons from which normal young emerge[4]. A clone of this flatworm was produced from a single individual by cycles of bisection and subsequent regeneration.

When the clone contained 160 adults, the worms were randomly distributed among 64 straight-sided bottles so that groups of 16 bottles contained 1, 2, 3 and 4 worms per bottle, respectively. One half of the worms, equally divided with respect to number of worms per bottle, were cultured in 40 ml of pond-water; the remainder were cultured in 80 ml. All animals were fed as much fresh mouse liver as they would consume three times a week, and following each feeding the water in the bottle was replaced with fresh pond-water.

Fig. 1 gives the number of cocoons produced per eight worms as a function of time.

Chi-squares for the differences between the various populations illustrated in Fig. 1 are given in Table 1.

Table 1.

	No. of worms per bottle 1 vs. 2	2 vs. 3	3 vs. 4	
40 ml. H_2O	7·5*	3·2	2·5	
80 ml. H_2O	8 7*	0·5	6 1†	
	No. of worms per bottle 1	2	3	4
Between 40 and 80 ml. per bottle	1 5	1 0	0 0	0 9

* Significant at the 99 per cent level.
† Significant at the 95 per cent level.

In a similar experiment (except that the design was factorial) 63 cocoons were produced within 64 bottles, each containing one worm, and 50 cocoons were produced in an equal number of bottles containing two worms each. The χ^2 for the difference is 25·5, which is very significant. In addition, 63 cocoons were produced by worms living in aerated water while 50 were produced by an equal number of worms which were not aerated but otherwise were living under similar conditions. The χ^2 here is 1·5.

The results of these experiments are consistent with the hypothesis that *Cura formanii* releases materials into the environment which inhibit reproduction by individuals of the species. The very small effect, if any, of aeration, indicates that the inhibitory material is not highly volatile and that the major inhibitory effect is not the result of change in concentration of dissolved oxygen or carbon dioxide. The lack of a demonstrable difference between the number of cocoons produced in 40 and 80 ml. of water indicates that cocoon production was not limited by scarcity of some substance present in the water and required for reproduction. The inhibitory effect is not decreased by the presence of snails (*Physa*) as is the case with the anti-growth factor produced by tadpoles.

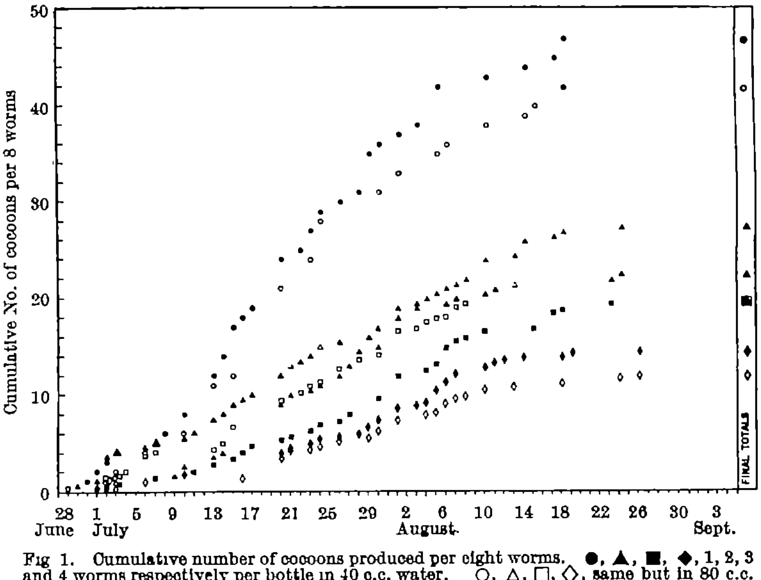

Fig 1. Cumulative number of cocoons produced per eight worms. ●, ▲, ■, ◆, 1, 2, 3 and 4 worms respectively per bottle in 40 c.c. water. ○, △, □, ◇, same but in 80 c.c. water

The growth inhibition mechanism of tadpoles does not prevent the production of many young individuals in an already crowded environment. The population regulation mechanism in *Cura formanii* is more efficient. Here, when the population density reaches a certain level, reproduction is inhibited and no further increase of drain on environmental resources occurs.

VIROLOGY

Properties of Bovine Virus Diarrhœa Virus

RECENTLY it has been shown[1] that a virus isolated from cattle with signs of 'mucosal disease'[2] is antigenically related to the virus of bovine virus diarrhœa[3]. In northern Sweden, a type of mucosal disease ('Umeå disease') was found to be accompanied or preceded by a respiratory disease. In paired serum samples from diseased animals increasing titres of antibodies were demonstrated against both bovine virus diarrhœa virus and para-influenza 3 virus[4], but only para-influenza 3 virus was isolated[5]. The incidence of infections with bovine virus diarrhœa virus among Swedish cattle seems to be about 20 per cent as judged from the results of a serological survey in 1959–60[4]. In the present work the properties on which Cooper[6] bases his classification of animal viruses have been investigated for bovine virus diarrhœa virus.

The bovine virus diarrhœa virus was represented by the strain Oregon *C24V*, which exerts a cytopathic effect on embryonic calf kidney cultures[7]. Since embryonic cells have a tendency to early spontaneous degeneration, new-born calf kidney cultures were used for propagation and titration of the virus. The maintenance medium consisted of Hanks's salt solution with 0·5 per cent lactalbumin hydrolysate.

The sedimentation coefficient of bovine virus diarrhœa virus was estimated by centrifugation in a Spinco model *L* centrifuge and compared with that of poliovirus type 1 and reovirus type 3. The viruses in infective tissue culture fluids were centrifuged in a *SW*39 rotor at different speeds and for different lengths of time and the supernatants titrated in roller tubes. In order to remove aggregates of virus the virus suspensions were pre-centrifuged for 1 hr. at 25,000*g* for poliovirus and bovine virus diarrhœa virus and for 1 hr. at 6,000*g* for reovirus. Poliovirus and reovirus were titrated in monkey kidney cultures and bovine virus diarrhœa virus in calf kidney cultures. The results for one experiment are recorded in Table 1. The bovine virus diarrhœa virus appears to sediment slower than reovirus and faster than poliovirus. The sedimentation coefficient of bovine virus diarrhœa virus was estimated to be approximately 80–90 Svedberg units (*S*). Since the calculated sedimentation coefficient of poliovirus is lower than the values reported previously[8], the value of bovine virus diarrhœa virus may actually be higher.

Table 1. ESTIMATION OF SIZE BY CENTRIFUGATION

Speed (r.p.m.)	Poliovirus* 1 hr.	Poliovirus* 2 hr.	Reovirus* 1 hr.	Reovirus* 2 hr.	Bovine virus diarrhœa virus* 1 hr.	Bovine virus diarrhœa virus* 2 hr
19,000	5 3	ND	4 7	ND	5 3	ND
27,000	4 9	4 9	3 7	ND	5·3	4 9
32,000	4·7	3 5	3 5	3·1	5 1	3 5
40,000	4 9	3 5	2 9	3·1	4·1	2·9
Sedimentation coefficient	60–80*S*		>180*S*		80–90*S*	

* Titre in neg. ^{10}log TCD_{50}/ml. of the supernatant.
ND, not done

The virus suspensions were filtrated through Millipore filters (Bedford, Mass.) of different pore size. Poliovirus and bovine virus diarrhœa virus passed through 50 mμ filters while reovirus was retained by 100 mμ filters (Table 2).

Table 2. ESTIMATION OF SIZE BY FILTRATION

Pore size (mμ)	Poliovirus*	Reovirus*	Bovine virus diarrhœa virus*
50	6 1	<0·5	1 1
100	7·5	<0·5	3 3
Not filtered	7·9	5 5	4 3

* Titre in neg. ^{10}log TCD_{50}/ml.

Electron micrographs of ultra-thin sections of virus pellets revealed a few spherical particles with a diameter of about 40 mμ. Specimens for electron microscopy were prepared from infective tissue culture fluid. The virus was concentrated in aqueous two-phase systems[9] and sedimented by centrifugation at 105,000*g* for 1 hr. Since the titre of the tissue culture fluid and disrupted cells never exceeded $10^{5\cdot7}$ TCD_{50}/ml. the concentration of virus in the pellet was too low to permit an identification of the spherical particles as the virus particles of bovine virus diarrhœa virus.

The sensitivity of the Oregon strain to ether and chloroform was tested according to methods described previously[10,11]. The Oregon virus was readily inactivated by these lipid-solvents and appears therefore to be a lipo-virus.

The type of nucleic acid of this virus was investigated by the use of 5-iodo-deoxyuridine, which is known as an inhibitor of synthesis of deoxyribonucleic acid (DNA)[12]. Calf kidney cultures containing 50 μgm. of the inhibitor per ml. medium were inoculated with bovine virus diarrhœa virus, and as a control, with bovine enterovirus and pseudorabies virus. The multiplication of pseudorabies virus, a DNA virus, was clearly inhibited by 5-iodo-deoxy-

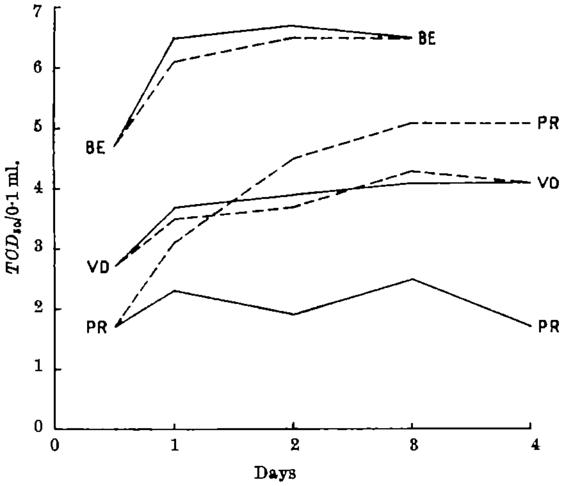

Fig. 1. Growth of different viruses with or without 5-iodo-deoxyuridine (IUDR) added to the medium. BE, bovine enterovirus; PR, pseudorabies virus; VD, virus diarrhœa virus. ——, with IUDR; – – –, without IUDR

uridine whereas bovine virus diarrhœa virus and bovine enterovirus were not inhibited at all (Fig. 1). Bovine virus diarrhœa virus can therefore be tentatively considered as an RNA virus.

Other compounds known as inhibitors of DNA synthesis[12–14] were also tested. 5-bromo-deoxyuridine[12] was found to be less inhibitory for the multiplication of pseudorabies virus than 5-iodo-deoxyuridine while 5-fluoro-deoxyuridine[13] and aminopterine[14] had no effect on the growth of this virus in calf kidney cultures. The results presented here confirm the observation[12] that 5-iodo- and 5-bromo-deoxyuridine are superior to other inhibitors of DNA synthesis in some species of cells.

The results of cross-neutralization tests showed no antigenical relationship between the Oregon strain and para-influenza-3 virus, infectious bovine rhinotracheitis virus, or bovine enteroviruses. On the other hand, hyperimmune swine fever serums had a neutralizing effect on the Oregon strain[15], and bovine virus diarrhœa virus will protect pigs against swine fever[16]. Darbyshire[17] has shown earlier that antigens in organ suspensions derived from pigs with swine fever and from cattle with a British mucosal disease[18] cross-precipitate in agar-gel.

To summarize, the bovine virus diarrhœa virus as represented by the strain Oregon *C24V* appears to be an RNA-containing lipo-virus with a size of approximately 40 mμ and antigenically related to the swine fever virus.

We are indebted to Prof. J. H. Gillespie, of Cornell University, for kindly supplying the Oregon strain.

Release of Deoxyribonucleic Acid from Vaccinia Virus by 2-Mercaptoethanol and Pronase

IN an earlier report the isolation of a single-stranded DNA from highly purified vaccinia virus was described[1]. The DNA was extracted under mild conditions with water-saturated phenol and deoxycholate, according to the standard procedure used for obtaining purified and undegraded nucleic acids from many other viruses and micro-organisms[2]. It was considered unlikely that this single-stranded DNA was derived by denaturation of originally double-stranded DNA as a result of phenol treatment; first, because there are no reports in the extensive literature that phenol extraction at 4° C. can cause such degradation, and secondly because salmon-sperm DNA treated in our laboratory with the identical procedure used for vaccinia showed no evidence of denaturation. Despite repeated attempts to improve the yield of phenol-extracted DNA from vaccinia, the method was quantitatively unsatisfactory as not more than 10–20 per cent of the total viral DNA was recovered. Alternative methods of isolating the DNA from the virus in higher yield and in as pure a form as possible have therefore been investigated.

Earlier workers disrupted vaccinia by treatment with 1 per cent sodium carbonate[3] or 5 per cent sodium hydroxide[4]. In our hands these classic methods, which were originally applied to virus cultivated on rabbit skin, released less than 1 per cent of the total DNA from the egg-adapted Levaditi strain purified with fluorocarbon. About the same efficiency of extraction (1 per cent) has been obtained on treatment with the following reagents: 2 per cent sodium lauryl sulphate[5], saturated guanidinium chloride[6], 8 *M* urea[7], 1 per cent sodium deoxycholate[8], and hot (50° C.) phenol[9]. Furthermore, we have found that treatment with *N* sodium hydroxide at 20° C., as used by Wyatt and Cohen[10] to disrupt vaccinia for base-ratio determinations, gave about the same yield as the above methods. Sonication (Raytheon-10*KC*) of fluorocarbon-purified vaccinia for 15 min. at 4° C. in the presence of 80 per cent phenol released about 50 per cent of the total DNA. Although this DNA was highly purified (260/280 mμ ratio of 2 0), the method was not pursued further since the DNA was undoubtedly being degraded[11]. Various combinations of enzymatic treatment (lysozyme, trypsin, chymotrypsin) also failed to release nucleic acid.

Strikingly similar difficulties have been encountered in attempting to liberate DNA from human and bull sperm[12]. Successful release of DNA from sperm was recently reported by Borenfreund, Fitt and Bendich by degrading the keratin-like outer membrane on incubation with 2-mercaptoethanol and trypsin[13]. This technique, with certain essential modifications, has now been applied to vaccinia with the result that we have routinely been able to extract 90–95 per cent of the DNA from the virus.

Purified virus[1] was washed once with absolute ethanol, deposited by centrifugation at 20,000*g* for 1 hr., and resuspended in a 1 : 1 mixture of absolute ethanol and ether (about 6 ml./5–10 mgm. dry weight of virus). The vaccinia was sedimented again and dried overnight in a 40° C. oven. The dried virus was resuspended in 5 ml. of 0·15 *M* sodium chloride–0·015 *M* sodium citrate, and sufficient 2-mercaptoethanol was added to bring the final concentration to 2 per cent. This suspension was then stirred slowly for 18–24 hr. at 4° C. During the first few hours of stirring it was important to break up clumped material with a glass rod. Slow stirring was then continued for 12 hr. at 37° C. in the presence of 0·5 mgm. 'Pronase'[14], a broad spectrum protease from *Streptomyces griseus* (Calif. Corp. Biochem. Res Lot. No. 109080). This was followed by centrifugation at 20,000*g* for 1 hr. After the supernatant was set aside, the pellet was resuspended in saline–citrate and 'Pronase', as above. This was stirred for 8 hr. at 37° C. and then treated exactly as before. A third cycle involved stirring for only 4 hr. The 3 supernatants were then combined and the DNA was sedimented in a Spinco *SW* 39 rotor at 35,000 r.p.m. for 5 hr. Thus, in contrast to the original method[12], the periods of incubation were generally longer, 'Pronase' was used instead of trypsin, and enzymatic digestion was carried out at 37° C. (at 4° C. only about 20 per cent of the total amount of DNA was released).

The sedimented DNA, its supernatant, and the final pellet containing disrupted vaccinia (the latter hydrolysed with 5 per cent TCA for 15 min. at 90° C. (ref. 14)) were analysed by the method of Keck[15]. Typical DNA content of these fractions was 96, 1, and 3 per cent respectively of the total contained in the virus. That vaccinia contains 5·6 per cent DNA[4] seems to be substantiated from our calculations based on the amount of DNA extracted in the present experiments from weighed samples of dried vaccinia. A typical nucleic acid absorption spectrum (260/280 mμ ratio of 2·0) was obtained from the mercaptoethanol-released DNA. The purity of this DNA was also established by following its thermal transition (temperature versus absorbance at 260 mμ)[1,16]. There was no detectable increase in absorbance up to 75° C., but thereafter a sharp rise in absorbance occurred with the midpoint of this rise, or T_m, at 84° C. This indicated that the bulk of the DNA was double-stranded. The average hyperchromic effect was about 25 per cent. Further treatment of the DNA with dupanol[11] or phenol[1] altered neither the absorption spectrum nor the T_m.

Base ratio analysis of the DNA was carried out by hydrolysis with 90 per cent formic acid (175° C. for 30 min.)[10], followed by chromatography using Whatman No. 1 filter paper and the standard isopropanol–water–hydrochloric acid solvent system[10]. A short wave-length 'Mineralight' was used to locate the ultra-violet absorbing spots, which were then eluted with 0·1 *N* hydrochloric acid. The absorbance of each base was determined in the Beckman *DU* spectrophotometer, and their concentration was calculated from the values of Bendich[17]. The mole per cent (based on two determinations) of adenine, thymine, guanine, and cytosine was 30, 31, 20, and 19, respectively. The guanine–cytosine content of 39 is consistent with that value predicted[16] by the T_m, and with that previously reported for vaccinia[10].

It would be of interest to determine whether the nucleic acid released by 2-mercaptoethanol contains a small fraction of single-stranded DNA, and, if so, whether this fraction is similar to that extracted from the virus by phenol. Assuming that the single-stranded DNA extracted in phenol is not produced by denaturation, as seems likely from past experience[18] and from our finding that the double-stranded DNA extracted with 2-mercaptoethanol has the same T_m after phenol treatment, then it seems possible that phenol preferentially extracts only one type of DNA from vaccinia (that is, single-stranded). Thus each virus particle may contain both types of DNA, or, alternatively, there may be two classes of virus particles, the majority containing double-stranded DNA and the remainder, possibly incomplete, containing single-stranded DNA. Since the presence or absence of a small single-stranded fraction in the DNA isolated by mercaptoethanol cannot be established by the thermal denaturation curves obtained, or from the base ratios, further experiments designed to clarify this point are in progress.

The failure of repeated attempts in our laboratory[19] and elsewhere (Fenner, F., personal communication) to isolate infectious DNA from vaccinia by the standard phenol procedures may well be due to the fact that phenol removes a relatively small atypical sample of the total DNA from the virus. Thus phenol may not be suitable for the preparation of infectious nucleic acids from certain large viruses, although it has been the standard reagent used for this purpose with many small DNA and RNA animal viruses[2]. Following our experience with vaccinia it seems that 2-mercaptoethanol might be worth investigating as a means of releasing nucleic acids, and possibly infectious nucleic acids, from other viruses. Preliminary attempts to demonstrate infectious DNA from vaccinia by this method have so far been unsuccessful.

Effect of Irradiation on Poliovirus Yield of Cultured Kidney Cells of the Rhesus Monkey

ALTHOUGH X-irradiation of established lines was followed by the formation of giant cells[1], irradiation of primary cells was not[2]. Irradiation of cells also consistently increased the poliovirus yield per cell in the established lines, but not in primary monkey kidney, which suggested a relationship between the formation of giant cells and the yield of virus[3]. This communication demonstrates that irradiated monkey kidney cells which consistently form giants also yield more poliovirus per cell.

Giant cells were obtained consistently when cell suspensions were prepared from monolayers of primary monkey kidney and were irradiated at the time of plating. For these experiments, monolayers of primary rhesus monkey kidney were treated with 0·05 per cent trypsin (Difco, 1 : 250) containing 0·15 per cent disodium dihydrogen 'Versinate' (Dow Chemical Co. Trade name for disodium salt of ethylenediamine tetraacetic acid dihydrate). The cells were distributed into 50-mm. Petri dishes (plastic) in a 20 per cent calf-serum lactal medium[3], at a level of 1×10^5 or 3×10^5 cells per dish, and were subjected to 1,500–2,000 r. of X-ray from a Westinghouse Industrial X-ray machine operating at 140 kV. and 9 m.amp., filtered with 0·25 mm. copper and 1 mm. aluminium. Control monolayers prepared at the same time were seeded with 5×10^4 or 1×10^5 non-irradiated cells. All plates were incubated at 37° C. in an atmosphere of 4 per cent carbon dioxide in air. The medium was renewed every 2–3 days until the plates were infected. Then the growth medium was removed, and the monolayers were washed once with phosphate-buffered saline[4], infected with 0·5 ml. of Leon strain type 3 poliovirus (titre: $1 \cdot 2 \times 10^8$ per ml.) in 0·5 ml. of phosphate-buffered saline, incubated for 1–1½ hr. at 37° to permit virus attachment, washed 3 times with phosphate-buffered saline, overlaid with Eagle's medium[5] enriched with 2 per cent calf-serum, and returned to the carbon dioxide incubator. When the cells had been destroyed, monolayers were collected.

For the counting of virus yields, cell suspensions were prepared at the time of infection from representative irradiated and non-irradiated monolayers, as described. Table 1 summarizes the results of several experiments in which monolayers were infected 6 or 7 days after plating. In all cases the irradiated cells yielded more virus.

Table 1. POLIOVIRUS YIELDS OF RHESUS MONKEY KIDNEY CELLS NON-IRRADIATED AND IRRADIATED ON THE DAY OF PLATING

Time of infection (No. days after plating)	Exp. No	Virus yield (plaque-forming units per cell) Non-irrad.	Irradiated
6	1	195	1,200
	2	160	425
	3	380	1,000
7	1	120	540
	2	208	1,150
	3	150	640

Since microscopic examination of the plates revealed that almost all cells were enlarged, an experiment was designed to determine the size of the irradiated and non-irradiated cells 6 and 7 days after plating. For calculation of cell volume, the monolayers were trypsinized and the diameters of the first 10 cells in each set were measured with a calibrated ocular micrometer. Both the major and the minor axes of ellipsoidal cells were measured. Since in the series studied the axial ratio never exceeded 1 : 4, the volumes were calculated as though the ellipsoidal cells were spheres with diameters equal to the mean of their major and minor axes. This resulted in an over-estimation of volume of no more than 25 per cent. Table 2 gives the mean volumes obtained, with their standard deviations. Irradiation obviously resulted in an increase in cell volume, as well as an increased poliovirus yield approximately equal to this increase in volume. A similar correlation for X-irradiated HeLa cells, which formed giants and yielded more Newcastle disease virus, was reported by Marcus and Tolmach[6].

Apparently the correlation between the development of large cells and an increase in virus yield, which was observed in non-irradiated cells by Dunnebacke and Reaume[7], applies also to irradiated cells.

Table 2. MEAN VOLUMES (WITH STANDARD DEVIATIONS) OF RHESUS MONKEY KIDNEY CELLS, NON-IRRADIATED AND IRRADIATED ON THE DAY OF PLATING

No. of days after plating	Cell volume Non-irradiated	Irradiated
6	$(1 \cdot 68 \pm 0 \cdot 82) 10^4 \mu^3$	$(9 \cdot 6 \pm 1 \cdot 71) 10^4 \mu^3$
7	$(1 \cdot 75 \pm 0 \cdot 57) 10^4 \mu^3$	$(7 \cdot 45 \pm 1 \cdot 35) 10^4 \mu^3$

SOIL SCIENCE

Free Monosaccharides in Soil Organic Matter

IN view of the vital importance of carbohydrate fraction of soil organic matter on physical and biochemical properties of soils, a number of workers[1–4] have elucidated the composition of soil polysaccharides by their work on the hydrolysates. The consensus of opinion is that the sugar residues comprise at least 5 per cent of the soil organic matter and the polysaccharides are composed of galactose, glucose, mannose, arabinose, xylose, and rhamnose. Brown, Robinson and Johnson[5] examined the effect of D-xyloketose on the roots of plants and observed that even a minute concentration of the carbohydrate can perform important physiological functions. The present work was designed to determine the presence of free monosaccharides in soils.

Four widely different pedological, vegetational and climatic type soils, namely, a half-bog soil from southern Delaware (Pocomoke), a prairie soil from Illinois (Sable), a red-yellow podzol from North Carolina (Cecil), and a tropical latosol from Brazil (samples passing through 60 mesh sieve) were used for the investigation. 1-kgm. samples of soil were extracted with 1 litre of 80 per cent alcohol five times at room temperature. The filtrates were concentrated under vacuum at 45° C. and reduced to dry residue by lyophilization. The residue was extracted with three 10-ml. portions of dry pyridine, and the pyridine was removed under reduced pressure. The pyridine-soluble material was extracted with 5 c.c. of 50 per cent aqueous isopropanol and centrifuged for 15 min. at 2,000 r.p.m. The supernatant was dried *in vacuo* at 45° and the residue taken up in 5 ml. of 50 per cent isopropanol. The centrifuging, decanting and drying steps were repeated a number of times. The residue was extracted with 1 ml. of 50 per cent aqueous isopropanol and was then used for the qualitative chromatographic determinations. 25λ of this solution was spotted for paper chromatography against known solutions of monosaccharides. The solvent was 4 : 1 : 5 *n*-butanol/acetic acid/water (organic phase in trough and aqueous phase in chamber). Ascending chromatography was used and the dried chromatograph was dipped in 2 per cent aniline trichloroacetate (in glacial acetic acid). This was air-dried and then oven-heated (110° C. for 5 min.). A similar determination of sugars was also made by the descending paper chromatographic technique using pyridine, butanol, glacial acetic acid and water (6 : 4 : 1 : 3) as solvent. The concurrent results by aforementioned two techniques are given in Table 1.

Table 1. FREE MONOSACCHARIDES PRESENT IN FOUR TYPICAL SOILS

Monosaccharides	Pocomoke soil	Sable soil	Cecil soil	Brazil soil
Galactose	—	–	–	—
Glucose	+	+	+	+
Mannose	–	–	–	–
Arabinose	–	–	–	–
Xylose	–	–	–	–
Fucose	–	–	–	–
Rhamnose	–	–	–	–

Sable soil and Brazil soil have two more same unidentified monosaccharides.

The present results indicate that common sugars exist in free condition in soil organic matter. It is very significant to note that glucose was observed in all the four samples. Further work is in progress on the determination of these sugars in widely different soil samples and to investigate the importance of this observation.

I thank Prof. G. T. Felbeck, jun., for advice.

Alteration in the Surface Properties of Soils by Ion Exchange Resins

WHEN soils suspended in glass-distilled water were labelled with phosphorus-32, the rapidly exchanging fraction of the isotopically labile phosphate reacted during the first 10 hr. according to a first-order mechanism, either by 'film' diffusion or by 'mass action'. Suspensions of the soils with mixed resins (Na^+ : 'Zeokarb 225', and Cl^- : 'Amberlite *IRA* 401') behaved quite differently. The rate at which this fraction of the soil phosphate was exchanged by chloride ions from the strongly dissociating resin exchanger was governed by 'bulk' or 'intra-particle' diffusion during 4 days. The mixed resins removed little or none of the remaining 'slowly' exchangeable part of the isotopically labile soil phosphate. (In the absence of resins, this 'slow' fraction exchanged isotopically according to a single 'bulk' diffusion mechanism.) Phosphate diffusion within the resin particle was not the factor controlling the rate of exchange in mixed suspensions of soil and resin because exchange equilibrium was reached in less than 15 min. with Cl : 'Amberlite *IRA* 401' alone in phosphate solutions.

A typical soil in water exchanged 4·8 mgm. of phosphorus per 100 gm. soil isotopically during 10 hr by first order kinetics. When reacted with the 'mixed' resin system the soil exchanged a maximum of 7·3 mgm phosphorus for Cl^- ions, of the same specific activity as the 'rapid' isotopically labile phosphate, in 4 days by 'bulk' diffusion kinetics. The apparent diffusion coefficient, D_i, for the movement of phosphate ions through soil particles of weighted mean diameter 2·9μ in the clay + silt fraction was 3·0 ± 0·5 × 10^{-10} cm.^{2} hr.$^{-1}$.

This evidence suggests that poly-electrolyte anions, products of the chemical and abrasive decomposition of resins, are formed when resin and soil are suspended in water. Phosphate ions held on the soil surface initially must diffuse to the soil solution through multi-layers of such surface-active poly-electrolyte anions on the soil. This leads to the large differences observed in both the mechanisms and the specific rate of exchange of phosphate ions in soil suspended in water with and without resins.

Anomalous surface effects on glass in conductivity water, prepared by using 'mixed bed' ion-exchange resins, have been attributed to weakly basic poly-electrolytes released from the resins[1]. These contaminants appear to be removed by passing through 'Millipore' filters[2], but their size prevents them from penetrating resin particles of opposite charge[3]. Similarly, non-chelating anions like monovalent phenyl-barbiturate 'block' soil pores and decrease the rate of isotopic exchange of the soil phosphate[4].

Increasing use is being made of resins to extract nutrients from the soil and to supply nutrients to plants in studying plant nutrition. Our work indicates that caution is needed in interpreting results from such experiments especially when considering rates of reaction and rates of uptake by plants.

In the example given here the 'slow' fraction of the isotopically labile phosphate, 12·8 mgm. phosphorus per 100 gm. soil, exchanged isotopically during 10–288 hr. with an internal self-diffusion coefficient, D_i^*, equal to 0·8 ± 0·1 × 10^{-10} cm.^{2} hr.$^{-1}$. This is a quarter of the diffusion coefficient obtained by 'mass flow' in the resin : soil system for the phosphate exchanging for Cl^- ions, suggesting that little of this 'slow' fraction would be extracted by the 'mixed' resins.

PSYCHIATRY

Isolation and Characterization of a Compound from the Urine of Schizophrenics

THE systematic screening of schizophrenic and normal urine in this laboratory has led to the identification of a biologically active compound in urine of schizophrenics. This compound is of particular interest since it does not have the usual sympathomimetic actions of the closely related catecholamines, but does have a depressant effect on the central nervous system[1].

Samples of urine were collected from a series of 19 schizophrenic patients and 14 normal subjects. Neither patients nor controls had been treated medically for at least 48 hr. and had received no tranquillizing drugs for a minimum period of two weeks. The diagnosis of schizophrenia was confirmed by two psychiatrists. The normal controls were selected from the surgical wards and hospital staff. The urine was customarily collected for a period of 20 hr., from noon–8 a.m., and was analysed immediately after the collection. Occasional urines were successfully refrigerated for 48 hr.

A creatinine determination was carried out initially and a volume of urine equivalent to 300 mgm. of creatinine constituted a sample. The urines were treated with barium chloride until no further precipitate formed. The sample was adjusted to 500 c.c. with distilled water and the urine was acidified to *p*H 2 with concentrated hydrochloric acid. Some samples were hydrolysed at this *p*H for 30 min. at 100° C. without effect on the unknown. The sample was then extracted three times with chloroform to remove interfering compounds. The aqueous portion was adjusted to *p*H 9 with 2 *N* sodium hydroxide and the urine was extracted three times with chloroform. These extractions were done quickly inasmuch as the unknown was readily oxidized in base. The organic phase was dried with anhydrous sodium sulphate and evaporated to suitable volumes for application for paper chromatography (an equivalent of 100 mgm. creatinine per spot). The chromatography was developed in butanol/acetic acid/water (4 : 1 : 1) for a period of 16 hr. and the compounds were located with ninhydrin-pyridine reagent. A blue-purple spot appeared repeatedly at R_F 0·60 which was not observed in extractions from samples of normal urine. Further investigations revealed that the application of a modified Ehrlich's reagent (2 gm. *p*-dimethylaminobenzaldehyde dissolved in 90 c.c. acetone and 10 c.c. concentrated hydrochloric acid) to the strips over the purple spot produced by dipping in ninhydrin-pyridine resulted in an immediate pink spot turning to orange on standing. This colour corresponded to the purple ninhydrin spot at R_F 0·60. In this test the strip was first dipped in ninhydrin-pyridine reagent (9 : 1), dried and heated at 80° C. for 1 min. at which time the ninhydrin colours appeared. The strip was then dipped in the modified Ehrlich's reagent. The appearance of a pink or orange spot after the purple ninhydrin spot fades is specific for β-phenylethylamine and other β-phenylethylamino compounds with a free amino-group and substituted only on the ring[2]. These compounds do not react with Ehrlich's reagent alone. Further characterization of the unknown spot revealed that it had an R_F of 0·79 in isopropanol/ammonia/water (200 : 10 : 20). It also produced a purple colour with ninhydrin-acetate reagent and did not fluoresce in the ultra-violet after this treatment. It should be noted that there is occasionally present a purple ninhydrin-pyridine reacting spot slightly slower but not always separated from the unknown. This interfering material has a strong red fluorescence in ultra-violet light: (360 mμ) after reaction with ninhydrin-pyridine and produces a blue colour rather than pink with modified Ehrlich's over ninhydrin.

The unknown did not react with diazotized sulphanilic acid reagent, nitraniline or 2,6-dichloroquinone chlorimide-borate buffer. It also resisted hydrolysis with hydrochloric acid at *p*H 2 for 30 min. These reactions demonstrate that the compound is not phenolic in character nor is it a conjugated phenol. The unknown substance produces a pale brown colour when the strip is sprayed with iodine in chloroform, and does not react with *p*-anisidine amyl nitrite reagent.

After a study of the β-phenylethylamines the above reactions were found to be consistent only with those for authentic 3,4-dimethoxyphenylethylamine (K. and K. Laboratories). This compound has the same R_F values as the unknown substance in the solvent systems described. Also, when 3,4-dimethoxyphenylethylamine is chromatographed with the unknown substance, it enlarges the unknown spot by an appropriate amount.

A dinitrophenyl derivative was made from the unknown substance and the reference compound and chromatographed in methanol/water (8 : 2). The R_F for the dinitrophenol-derivative of both the unknown and the reference was 0·60. Both the unknown and the reference were oxidized to 3,4-dimethoxyphenylacetic acid with potassium permanganate. The R_F of the unknown substance and the reference both coincided with authentic 3,4-dimethoxyphenylacetic acid (butanol/acetic acid/water, 4 : 1 : 1, R_F 0·91).

Identical spectra were obtained from hydrochlorides made from both the unknown and the reference compound (absorption max. 234 mμ and 279 mμ, water).

Thus far, we have demonstrated the presence of a compound, 3,4-dimethoxyphenylethylamine, in the urine of 15 patients with a confirmed diagnosis of schizophrenia. In 2 additional patients a substance which had a bright red fluorescence in ultra-violet, after the application of ninhydrin-pyridine, interfered with the procedure. In 2 patients 3,4-dimethoxyphenylethylamine could not be detected. As yet we have not been able to identify this compound in the urine of the normal subjects examined.

It is necessary that these results be interpreted with considerable caution at the present time. Since we have succeeded in identifying the unknown compound, we plan to investigate additional normal controls inasmuch as we are now able to formulate more specific and sensitive methods. Also, many other possible experimental variables remain to be examined. If this compound does in fact represent an abnormal metabolite it would suggest the presence of a 4,*O*-methyltransferase in schizophrenic patients. It has already been demonstrated that 3,4-dihydroxyphenylethylamine can be metabolized by the action of 3,*O*-methyltransferase in brain homogenates[3]. Recently it has also been shown that 3,4-dihydroxyphenylethylamine can undergo 4,*O*-methylation in liver homogenates *in vitro* in the presence of *S*-adenosyl methionine[4]. We are conducting further investigations to determine the significance of 3,4-dimethoxyphenylethylamine and its possible enzymatic origin.

This research was supported by U.S. Public Health Research Career Development Award No. *MSF*-14,024. We thank Dr. Irving Goodman for helpful discussions.

Wednesday, June 6

University of London (at the Postgraduate Medical School of London, Ducane Road, London, W.12), at 2 p.m.—Dr. A. E. Mourant. "Blood Groups, Populations, and Races".*

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. F. G. H. Blyth: "The Structure of the North-eastern Tract of the Dartmoor Granite".

British Nuclear Energy Society (at the Institution of Civil Engineers, 1–7 Great George Street, London, S.W.1), at 5.30 p.m.—Dr. J. M. Kay and Dr. S. C. Curran: "Nuclear Education" (two papers).

University of London (in the Gustave Tuck Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. John Chadwick: "The Decipherment of Linear B—The First Ten Years".*

Women's Engineering Society, London Branch ((at "Hope House", 45 Great Peter Street, Westminster, London, S.W.1), at 7 p.m.—Annual General Meeting.

Thursday, June 7

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Prof F. S. Dainton, F.R.S., and Mr. D. B. Peterson: "Forms of H and OH Produced in the Radiolysis of Aqueous Systems"; Mr. M. Z. Hoffman and Prof. G. Porter, F.R.S.. "Radiationless Conversion from the Triplet State".

Mineralogical Society (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—General Meeting.

University of Leeds (in the Arts Lecture Theatre, The University, Leeds), at 5.15 p.m.—Prof. P. P. Ewald, F.R.S. (Polytechnic Institute of Brooklyn): "William Henry Bragg and the New Crystallography"* (First Bragg Lecture).

Institution of Polish Engineers in Great Britain, Group for Economic, Social and Management Studies (at 55 Princes Gate, Exhibition Road, London, S.W.7), at 7 p.m.—Mr. M. C. C. M. d'Abranyi. "English Versus Continental Attitudes in Education".

Chemical Society (at Burlington House, Piccadilly, London, W.1.), at 7.30 p.m.—Scientific Papers.

Friday, June 8

Biochemical Society (in the Department of Biochemistry, The University, Edinburgh), at 10 a.m.—Scientific Papers.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Head (with an honours degree in mathematics, suitable teaching experience, and preferably industrial or research experience in a related field) of the Department of Mathematics (Grade III), Enfield Technical College, Queensway, Enfield, Middlesex—The Chief Education Officer (F.1), Middlesex County Council, 10 Great George Street, Westminster, London, S.W.1 (June 7).

British Nylon Spinners Post-doctoral Fellowship in Physics—The Registrar, The University, Bristol 8 (June 8).

Lecturer (with a good honours degree in physics or electrical engineering, together with experience in the field of communications, rather than in electronics) in Telecommunications—The Clerk to the Governors, Woolwich Polytechnic, London, S.E.18 (June 8).

Demonstrator in Agriculture, for duties on the University Farms—The Registrar, The University, Leeds 2 (June 9).

Demonstrator or Assistant Lecturer (medically qualified and/or a good honours degree in physiology) in Physiology—The Registrar, The University, Manchester 13 (June 9).

Lecturer in Theoretical Chemistry—The Secretary of University Court, The University, Glasgow (June 9).

Lecturers (2) in the Department of Mathematics—The Secretary, The University, Edinburgh (June 9).

Research Assistant (with postgraduate experience of research in mycology and plant pathology, preferably to Ph.D. level) in the Department of Botany, to participate in a research project in plant pathology which is supported by a grant from the Agricultural Research Council—The Registrar, The University, Manchester (June 9).

Lecturer or Assistant Lecturer in Analytical Chemistry—The Clerk to the Governors, Chelsea College of Science and Technology, Manresa Road, London, S.W.3 (June 13).

Lecturer (with a good honours degree, and preferably a special interest in the design aspects of digital computers, or in low temperature developments) in Electrical Engineering—The Registrar, King's College (University of London), Strand, London, W.C.2 (June 15).

Lecturer in Philosophy—The Registrar and Secretary, King's College (University of Durham), Newcastle upon Tyne (June 16).

Lecturer or Assistant (with special interests in economic statistics and econometrics) in the Department of Statistics—The Secretary, The University, Aberdeen (June 16).

Research Assistant in Physiology—The Registrar, The University, Sheffield (June 16).

Research Assistant (science or medical graduate) in the Department of Physiology, for the study of contact inhibition and invasiveness of malignant cells—The Registrar, The University, Bristol (June 16).

Lecturer or Assistant Lecturer (Probationary) (man or woman graduate) in Psychology—The Secretary, Bedford College (University of London), Regent's Park, London, N.W.1 (June 22).

Assistant Lecturer in Pure Mathematics—The Registrar, The University Sheffield (June 23).

Chair of Geology; and Lecturer or Assistant Lecturer in Geology at the University College Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (June 23).

Senior Lecturer or Lecturer (preferably specialist in pure mathematics) in the School of Mathematics, The University of New South Wales—The Agent-General for New South Wales, 56–57 Strand, London, W.C.2; and the Appointments Section, The University of New South Wales, Box 1, Post Office, Kensington, N.S.W., Australia (June 29).

Lecturer in Mathematics at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, June 30).

Lecturer in Physics at Rhodes University, Grahamstown, South Africa—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa and London, June 30).

Senior Lecturer or Lecturer in Mathematics at Wollongong University College, The University of New South Wales—The Agent-General for New South Wales, 56–57 Strand, London, W.C 2; and the Appointments Section, The University of New South Wales, Box 1, Post Office, Kensington, N.S.W., Australia (June 30).

Senior Lecturers or Lecturers (with a special interest in agronomy, animal husbandry, agricultural botany, agricultural zoology, agricultural chemistry or soil science) in the Faculty of Agriculture, Ahmadu Bello University, Northern Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (June 30).

Teaching Fellow (with an honours degree or equivalent qualification) in the School of Chemistry, University of New South Wales, to undertake research for a higher degree, preferably in organic chemistry, and also some teaching duties—The Agent-General for New South Wales, 56–57 Strand, London, W.C.2; and the Appointments Section, The University of New South Wales, Box 1, Post Office, Kensington, N.S.W., Australia (June 30).

Professor or Senior Lecturer (with a first degree in agriculture, or preferably horticulture together with M.Sc. and/or Ph. D. degrees, with preference for a Ph.D. in a strictly horticultural subject) in Horticulture at the University of Khartoum—The Registrar, University of Khartoum, c/o Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (July 30).

Lecturer (with a science degree specializing in geology, and research experience to Ph.D. or comparable level) in Geology (Palæontologist) at the University of Queensland, Brisbane—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (London and Brisbane, July 31).

Assistant Master to teach Chemistry up to G.C.E. "A" and "S" levels—The Headmaster, Wrekin College, Wellington, Shropshire.

Chemist (with a first- or good second-class honours degree in chemistry, or an equivalent qualification, and preferably experience in the inorganic analytical field and a knowledge of geochemical techniques) in Nyasaland, to take charge of the Geological Survey Department's chemical laboratory and to undertake assaying and chemical testing of rocks, including full silicate rock analyses—The Director of Recruitment, Department of Technical Co-operation, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting Ref. *T*/RC 218/110/01.

Lecturer, and an Assistant Lecturer (Grade B) to teach Chemistry mainly to G.C.E. "A" level and Ordinary National Certificate courses—The Principal, Cambridgeshire College of Arts and Technology, Collier Road, Cambridge.

Lecturer (man or woman, with good academic qualifications, and preferably with experience in schools) to teach General Science and Biology—The Principal, Avery Hill Training College, Bexley Road, Eltham, London, S.E.9, quoting Ref. TS.3/T/1109/5.

Master to teach Mathematics, mainly to Sixth Form—The Headmaster, Latymer Upper School, London, W.6.

SALARIES AND THE EXPANDING BRITISH UNIVERSITIES

THE motion which was moved by the Leader of the Opposition, Mr. Hugh Gaitskell, in the House of Commons on April 5 was concerned with two distinct but related issues arising out of the statement which the Chief Secretary to the Treasury, Mr. H. Brooke, made on March 14. The rejection of the recommendations of the University Grants Committee regarding the provision for university expansion raises the whole question of the scale of university expansion in the quinquennium 1962–67 and indeed of higher education in general in that period. The statement regarding the salaries of university teachers bears no less closely on that expansion, because, even before the statement from the Exchequer, the limiting factor in the rate and scale of university expansion was not so much the financial resources available as the ability of the universities to recruit teachers of the requisite capacity and to retain their services in the face of competitive demands.

To look first at this question of university staff may perhaps help to put the problem of university expansion and its finance in proper perspective, particularly as even the debate on April 5 scarcely removes the doubts expressed in the universities that neither Parliament nor electorate is fully convinced of the importance of the universities or appreciates their significance in relation to national survival. Moreover, the question of recruiting and retaining staff touches closely a further matter which in recent months has been causing serious concern outside as well as within the universities—the question of the scale and balance of university research. The research effort of the universities is a matter of staff as well as of facilities and the two are largely interdependent.

It is, in fact, the more important that the implications of the Government decision not to authorize an increase of more than 3 per cent in the bill for academic salaries at present, although the scales will be reviewed afresh next year, should be clearly understood in that, as Mr. Gaitskell rightly said, university teachers do not much like getting involved in politics and are normally disinclined to make a fuss about salaries and conditions of service. Indeed, even now, the dissatisfaction of the teachers themselves seems to centre as much on the disagreement between the Government and the University Grants Committee revealed in Mr. Brooke's statement as on the treatment of their claim for an increase in salaries. Mr. Gaitskell, nevertheless, showed clearly that it is the very moderation and restraint with which this claim, originally advanced in November 1959, for an increase of 15–20 per cent has been put forward, although in the meantime further increases have been awarded both in the Civil Service and to lecturers in technical colleges, that has put them in a relatively unfavourable position. The University Grants Committee, after hearing evidence, agreed to present a further claim on behalf of the university teachers in April 1961, and only submitted the claim in July 1961, as was indicated in the Committee's survey published last September.

It is in these circumstances that it is difficult to accept the Government's rigid application of the pay pause or to entertain the confidence which Mr. Brooke expressed on April 5 that neither recruiting nor staff numbers would suffer. Mr. Brooke himself admitted that the university teaching staff had been treated less generously than teachers, and that the former stood at some disadvantage in the negotiating arrangements. He could, however, scarcely have hoped to command assent to his view that the universities now offer a much better career prospect than the colleges of technology.

Nevertheless, there is substance in the argument that rigid comparison between the remuneration of different posts is full of difficulties, and it is hard to say what is proper remuneration of high intellectual attainment in any sphere. University salaries are unlikely ever to compete in such terms with posts in industry, and in some respects university posts are unique and owe their attractiveness to the nature of the work and conditions. If, however, the basic remuneration falls below a certain level that attraction ceases to function, and it is a key contention in the present situation that the starting level for an assistant lecturer of £800 or £1,050 for a lecturer, compared with £1,600 in a college of technology has been allowed to fall below the point at which that attraction can exert its normal and reasonable effect.

Mr. Brooke claimed indeed that in recent years recruitment to the higher ranks of the Civil Service had been feeling the competition of the attraction of a university appointment, rather than vice visa; but there is no evidence one way or another in the recent report of the Civil Service Commissioners. Moreover, it is all to the good that there should be a certain amount of interchange, as was strongly emphasized in the Zuckerman Report, and from that point of view alone, the gap between scales in the Civil Service and in the universities should not be allowed to become too wide. Further, in reaffirming that the 3 per cent increase in salary bill had been fixed in accordance with national considerations which extended far beyond the position of the universities, Mr. Brooke added that, while it was not for the Government to say how the 3 per cent increase should be distributed, the Government was prepared to accept the recommendation of the University Grants Committee that the increase should be concentrated on lecturers and assistant lecturers.

In concluding the debate on April 5, the Financial Secretary to the Treasury, Sir Edward Boyle, pointed out that it should not be supposed that the cost of salary increases had to be met out of the ordinary recurrent grant. During the present quinquennium, earmarked grants for salaries had already been made twice and the present award would require a further addition to the £8·75 million earmarked in the present year. He agreed that the real test of a university salary scale must be whether it attracts and retains the right numbers of staff. There was nothing else like universtiy work, and one could not arrive at right figures for salaries simply by means of external comparison.

Sir Edward Boyle spoke at the end of a debate in which, however, not only Mr. Gaitskell but also other speakers, such as Mr. J. Grimond, Mr. F. Mulley and Mr. F. Willey, had quoted instances of the universities losing staff to the colleges of technology as well as overseas. Mr. Willey, in particular, referred to the evidence recently submitted to the Robbins Committee by the Institute of Physics and the Physical Society on the loss of physicists to the United States and Canada. Apart from the list of some seventy British physicists now holding senior permanent appointments in America appended to this report, the report supplied disturbing evidence that conditions in British universities were for the first time failing to attract physicists of the front rank and that at a time when the projected expansion called for a net annual increase of some seventy-five physicists.

This is partly due to insufficient salaries, but only partly in the sense that is represented by the 3 per cent award. It arises to some extent out of the low proportion of senior posts, and this is a problem that affects the science departments at least generally. Sir Howard Florey put the point plainly in his anniversary address to the Royal Society on November 30, 1961. It is the promotion prospects that, coupled with the low salaries for lecturers and assistant lecturers, are responsible for the present anxiety over the staffing of British universities, and this anxiety found free expression at the discussion on the university teaching profession at the Home Universities Conference last December. Dr. Chilver flatly questioned whether it was reasonable to accept a proportion of 30 per cent of all staff for professors and other senior staff, and pointed out that the proportion of professors throughout the universities appeared to be only three-fifths of what it was before the Second World War. Prof. R. L. Brett's analysis of the returns from the University Grants Committee suggested that the chances of a lecturer or assistant lecturer becoming a professor were only about half what they were in the pre-war years: the ratio had fallen from 1 professor to 1·7 lecturers in 1937–38 to 1 to 3·5 in 1959–60.

The difficulty is not simply one of wide discrepancies in prospects between one faculty and another, but also avenues of promotion being blocked by age structure and mobility between one university and another being restricted. Mr. D. W. Reece, of the Association of University Teachers, was obviously most disquieted about the situation in December, and a memorandum submitted in March by the Manchester Local Association to the Robbins Committee argued that, quite apart from the widening of the gap between university salaries and those in comparable professions, the barriers to promotion and the 2: 7 ratio of senior to junior posts were already responsible for some migration of staff. Nor is it very likely that the development of the new university institutions will improve the situation, and, in any event, it must be remembered that, altogether apart from the salary scales in force, the universities have to budget for the appropriate rises on those scales in their recurrent expenditure each year. Taken with the automatic increase in expenditure on non-academic salaries—administrative, technicians-clerical, maintenance and the like—arising out of scales over which the universities have no control, as well as out of deliberate efforts to improve conditions which are responsible for waste of highly trained manpower and in which the universities often compare badly with research institutions either in Government or in industry—much of the 55 per cent increase in the Government recurrent grant will be absorbed in such ways before the universities can begin to plan to meet the needs of 35 per cent more students. The universities are already seriously considering, for example, a marked increase in the number of technicians available for the science departments.

This aspect was virtually ignored by both Mr. Brooke and Sir Edward Boyle from the Government side, although it was strongly put by Mr. G. Johnson Smith in the debate, who pointed out that the universities were facing a most significant rise in unavoidable charges, which were likely to absorb the extra money and leave none available for expansion. He welcomed Mr. Brooke's statement that if building costs became inflated the Government intended to insulate the universities by increasing non-recurrent grants for the building programmes, but this appears to be the only point at which the Government appears to have faced fairly the full implications of the request to the universities to provide for an expansion to 150,000 students by 1966–67. Even so, it seems optimistic to assume that any adjustment of the non-recurrent grants previously arranged is contemplated sufficient for the rise in costs which has already occurred and to falsify the belief of the Committee of Vice-Chancellors and Principals that the building programme to increase the number of places to 150,000 cannot be completed by 1966–67.

Apart from this, however, the Vice-Chancellors and Principals do not believe that this target can be achieved by that date with the limited recurrent grants now proposed by the Government. To disregard the other obligations of the universities in an attempt to come as near as possible to this target would inevitably result in a wholly unacceptable deterioration of standards, not only in staff–student ratios and research but also in academic and residential accommodation. The staff–student ratio has some bearing on the general question of staff, for the full impact of the salary situation cannot be appreciated except in the context of the past decade or more—a period of unprecedented expansion in which university teachers have often been desperately improvising and looking forward for improved conditions in which fuller justice could be done to the university ideal. Still more is this true of research, and here one of the keenest notes of anxiety in the universities is as to the effect of the Government decision on the scale and quality of university research.
